## 24.5 Functional description

The following sections describe functional details of the SEMC module.

### 24.5.1 Clocks

This section describes clocks and special clocking requirements of the SEMC module.

There is only one clock domain which is used for AXI bus interface, IP bus interface, internal logic and external interface.

## 24.5.2 Reset

This section describes how to reset the SEMC module and explains special requirements related to reset.

## 24.5.3 Pin Mux in SEMC

This table describes the pin mux in SEMC module.

Signal	SDRAM	NAND	NOR	SRAM	DBI (Display Interface)	Comment
SEMC_DAT A00	D0	D0	D0/A0	D0/A0	D0	HW MUX SEMC will determine the pin function according to its internal state (which device is been accessing).

## 24.5.4 Device access by AXI Command

Devices could be read/written by AXI bus access directly. AXI command is the device access sequence triggered by AXI bus access. The device access sequence for AXI command will be described in the following sections.

### NOTE

- The AXI bus memory map for each device is defined by SEMC\_BRx registers.
- There is no software configuration or polling need for AXI command except SEMC controller initialization. AXI master access external flash device transparently similar as normal AXI slave.

- AXI command is normally used to read/write access device memory space. IP command should be used to any other access, such as device register/OTP space access, device initialization.
- IP command could be used for memory read/write also similar as AXI command. But it's not recommended if only AXI command is available.

### 24.5.5 Device access by IP Command

Device could be accessed (initialized/configured/read/written) by IP bus access also. IP command is the device access sequence triggered by IP bus access. The device access sequene for IP command will be described in the following sections.

Device access could be triggered by IP command in following steps:

1. Set register IPCR0/IPCR1/IPCR2/IPTXD for Device address/Data Size/Write Data/Write Mask.
2. Set register IPCMD with valid command code (IPCMD.CMD) and command key (IPCMD.KEY).
3. Wait for IP Command Done (Wait for interrupt IPCMDDONE generated).
4. Read the device data from IPRXD. This is needed for read access only.

#### NOTE

- If device address or command code setting is not valid, there will be IP command error interrupt generated (INTR.IPCMDERR) and no device access at all.
- If another IP command triggered when the previous IP command not finished yet, there will be IP command error interrupt generated.
- IPCR0/IPCR1/IPCR2/IPTXD is protected when IP command triggered by not finished yet. Any write access to these register will be ignored.
- IPCR0 device address field should be configured even the device don't need any address bit information such as WRITE ENABLE command. SEMC need the device address to determine which device should be accessed.

### 24.5.6 SDRAM Controller Operations

This section describes the SDRAM controller module's operations.

### 24.5.6.1 SDRAM address map

SDRAM device address map on SoC is indicated in following diagram:

SDRAM device address map when SDRAMCR0.PS=0x1 (16 bit mode)

SDRAM device address map when SDRAMCR0.PS=0x0 (8 bit mode)

**Figure 24-2. SDRAM device address map**

### 24.5.6.2 SDRAM device access by IP Command

Following SDRAM device access could be triggered by IP command:

1. SELF REFRESH
2. AUTO REFRESH
3. MODE REGISTER SET
4. PRECHARGE
5. PRECHARGE ALL
6. ACTIVE
7. READ
8. WRITE

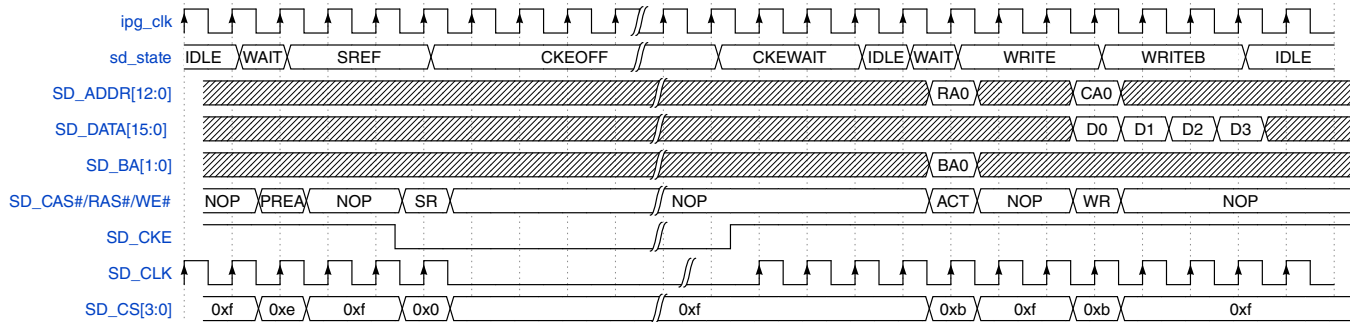

#### 24.5.6.2.1 IP command - SDRAM Self Refresh

When IP command triggered with command code - SELF REFRESH to any SDRAM device, SEMC would send SELF REFRESH command to all SDRAM devices. After SELF REFRESH command finished, all SDRAM device should be in self refresh state and SEMC will keep this state on SDRAM interface (SEMC\_CKE=0x0 and SEMC\_CLK=0x0).

SEMC will bring all SDRAM device out from self refresh state when there is any new IP command or AXI command triggered to SDRAM device.

## Functional description

Following timing diagram illustrates the sequence for self-refresh entering and exiting by AXI command.

**Figure 24-3. IP command - SDRAM Self Refresh**

### 24.5.6.2.2 IP command - SDRAM Auto Refresh

When IP command triggered with command code - AUTO REFRESH, SEMC would send AUTO REFRESH command to the SDRAM device accessed.

Following timing diagram illustrates the sequence for IP command - AUTO REFRESH.

**Figure 24-4. IP command - SDRAM Auto Refresh**

### 24.5.6.2.3 IP command - SDRAM Mode Register Set

When IP command triggered with command code - Mode Register Set, SEMC would send MODE REGISTER SET command to the SDRAM device accessed.

Following timing diagram illustrates the sequence for IP command - MODE REGISTER SET.

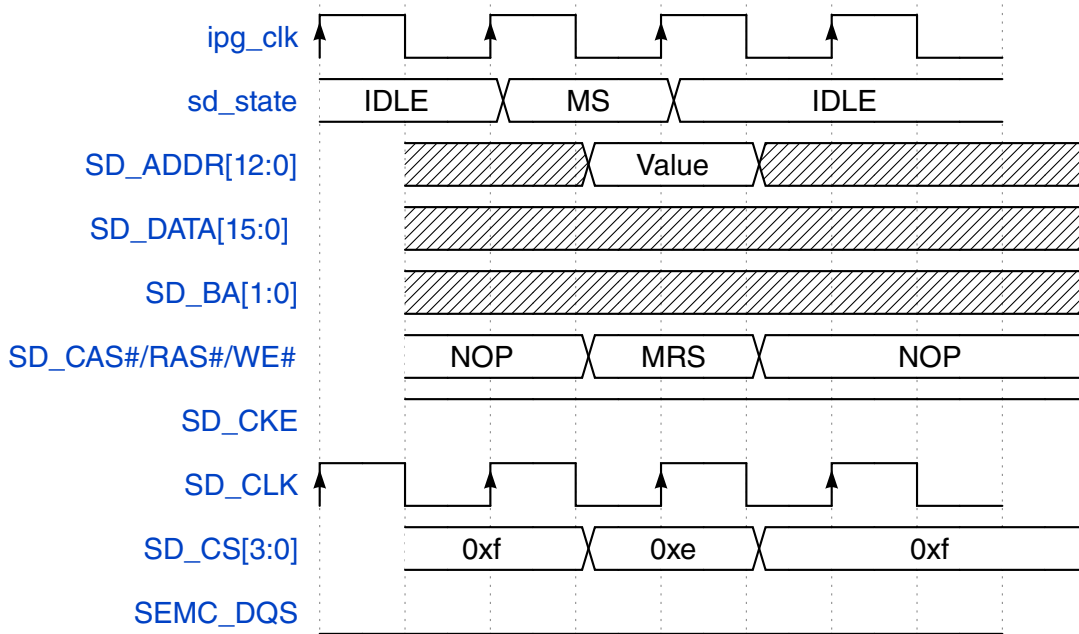

Figure 24-5. IP command - SDRAM MODE REGISTER SET

### 24.5.6.2.4 IP command - SDRAM Precharge

When IP command triggered with command code - Precharge, SEMC would send PRECHARGE command to the SDRAM device accessed.

Following timing diagram illustrates the sequence for IP command - PRECHARGE.

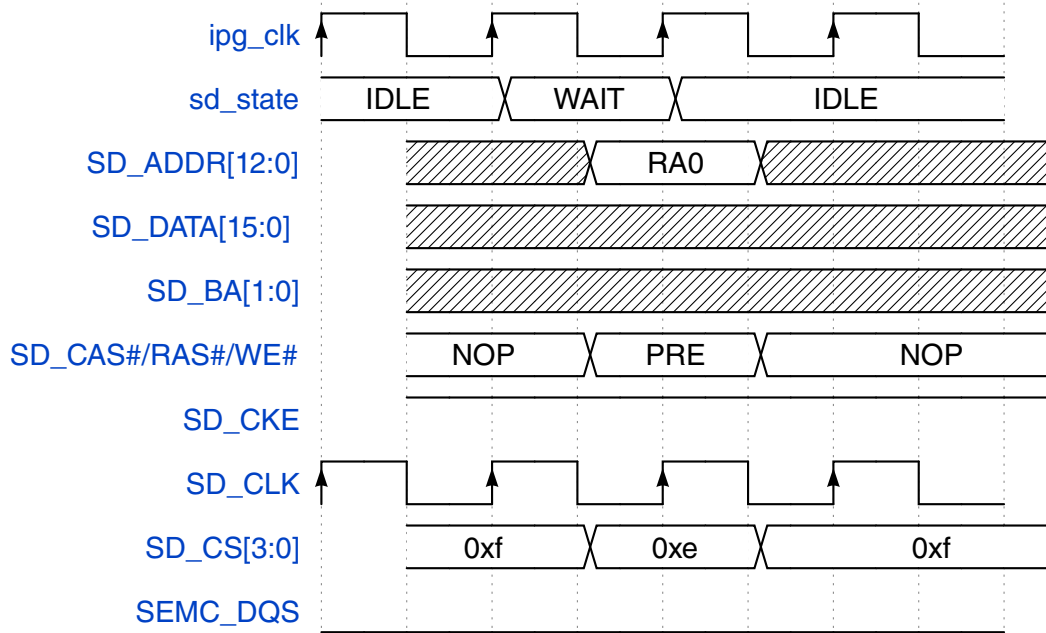

Figure 24-6. IP command - SDRAM PRECHARGE

#### 24.5.6.2.5 IP command - SDRAM Precharge ALL

When IP command triggered with command code - Precharge ALL, SEMC would send PRECHARGE ALL command to the SDRAM device accessed.

Following timing diagram illustrates the sequence for IP command - PRECHARGE ALL.

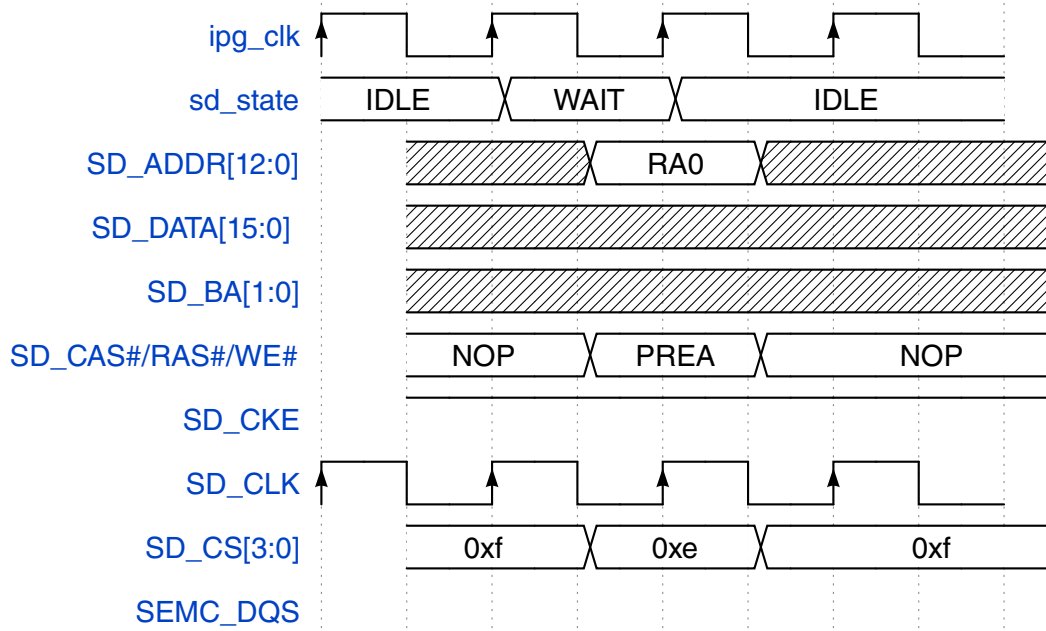

Figure 24-7. IP command - SDRAM PRECHARGE ALL

### 24.5.6.2.6 IP command - SDRAM Active

When IP command triggered with command code - Active, SEMC would send ACTIVE command to the SDRAM device accessed.

Following timing diagram illustrates the sequence for IP command - ACTIVE.

Figure 24-8. IP command - SDRAM PRECHARGE ALL

### 24.5.6.2.7 IP command - SDRAM READ

When IP command triggered with command code - READ, SEMC would send READ command to the SDRAM device accessed.

Following timing diagram illustrates the sequence for IP command - READ.

Figure 24-9. IP command - SDRAM READ

### 24.5.6.2.8 IP command - SDRAM WRITE

When IP command triggered with command code - WRITE, SEMC would send WRITE command to the SDRAM device accessed.

Following timing diagram illustrates the sequence for IP command - WRITE.

Figure 24-10. IP command - SDRAM WRITE

### 24.5.6.3 SDRAM device access by AXI Command

SDRAM device read/write access could be triggered by AXI Command. For AXI read access, SEMC would send READ commands to SDRAM device automatically and return data on AXI bus. For AXI write access, SEMC would save AXI bus write data and send WRITE commands to SDRAM device automatically

#### 24.5.6.3.1 SDRAM device read access by AXI Command

Following timing diagram illustrates the SDRAM device access triggered by AXI command (Read).

Figure 24-11. AXI command - SDRAM Read

### 24.5.6.3.2 SDRAM device write access by AXI Command

Following timing diagram illustrates the SDRAM device access triggered by AXI command (Write).

Figure 24-12. AXI command - SDRAM Write

### 24.5.6.3.3 SDRAM device pipelined access by AXI Command

Following timing diagram illustrates the SDRAM device pipelined read access triggered by AXI command (Read).

## Functional description

**Figure 24-13. AXI command - Pipelined SDRAM Read**

Following timing diagram illustrates the SDRAM device pipelined write access triggered by AXI command (Write).

**Figure 24-14. AXI command - Pipelined SDRAM Write**

### 24.5.6.3.4 SDRAM back-to-back access

This section describes the SDRAM back-to-back access.

#### 24.5.6.3.4.1 SDRAM read-to-read access

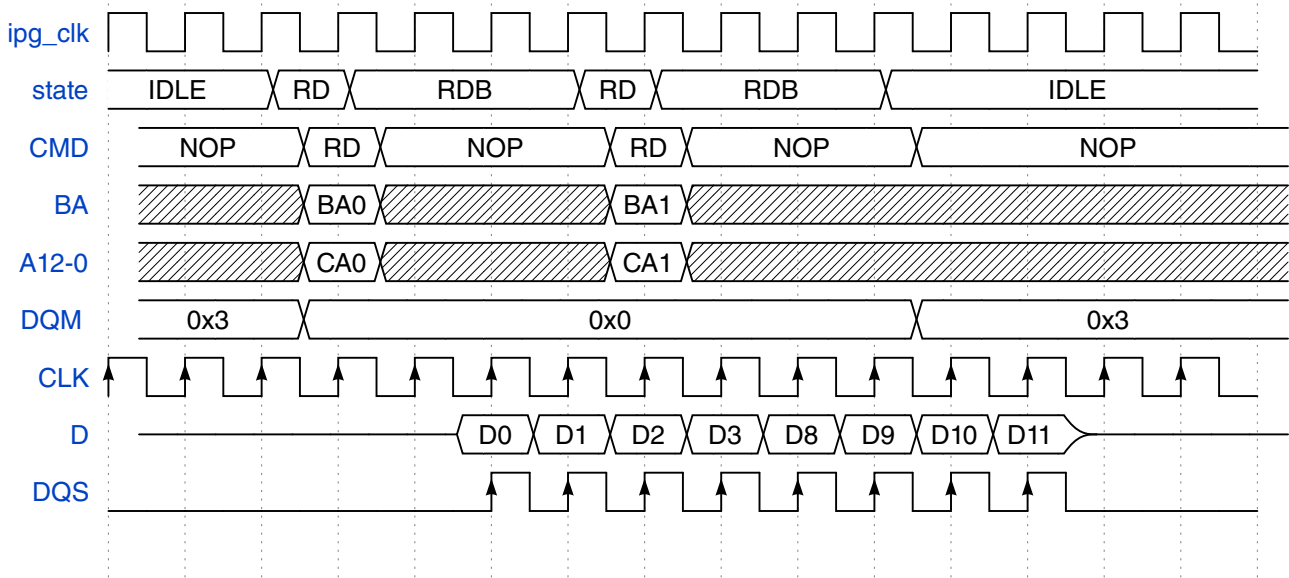

SDRAM read-to-read access timing when CL=1 is as following:

**Figure 24-15. SDRAM Read-to-Read access (CL=1)**

SDRAM read-to-read access timing when CL=2 is as following:

**Figure 24-16. SDRAM Read-to-Read access (CL=2)**

SDRAM read-to-read access timing when CL=3 is as following:

Functional description

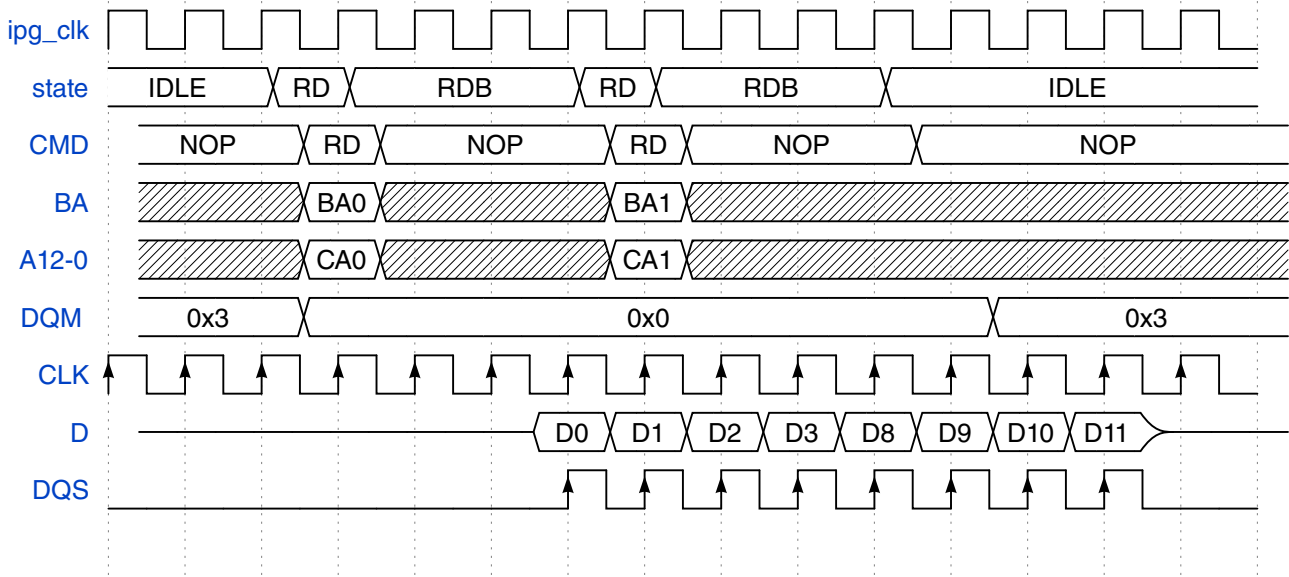

Figure 24-17. SDRAM Read-to-Read access (CL=3)

24.5.6.3.4.2 SDRAM read-to-write access

SDRAM read-to-write access timing when CL=1 is as following:

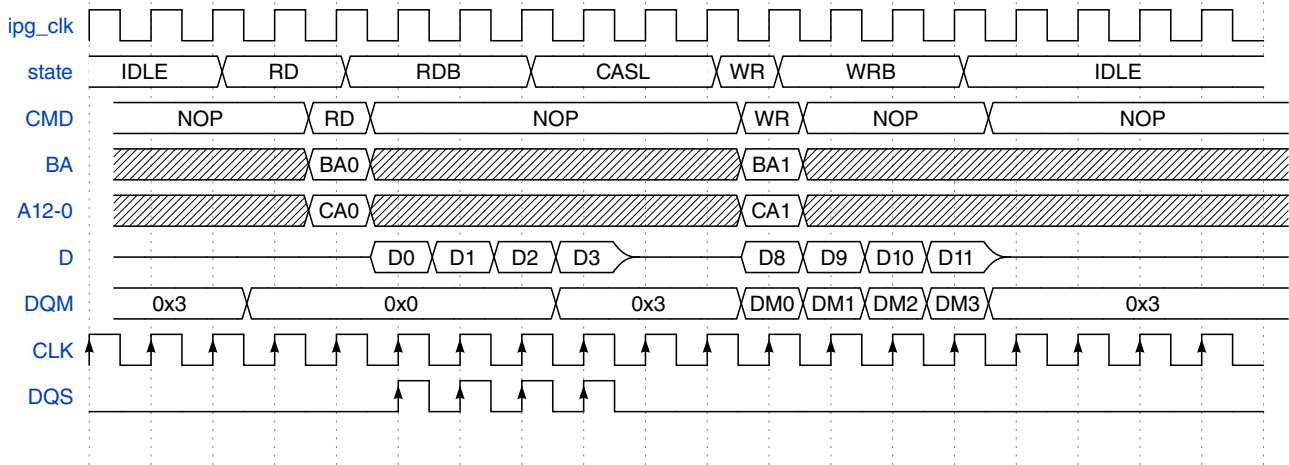

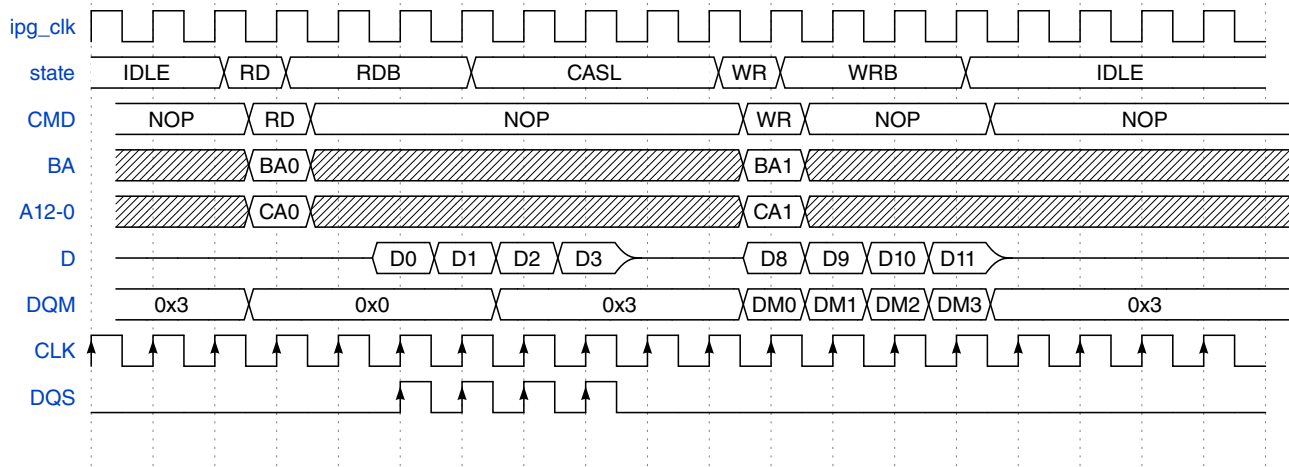

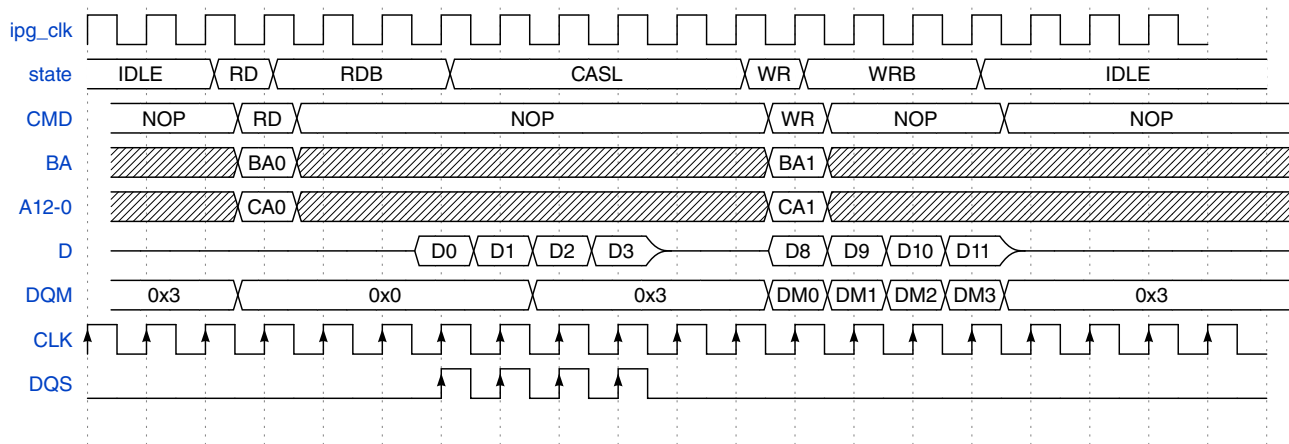

Figure 24-18. SDRAM Read-to-Write access (CL=1)

SDRAM read-to-write access timing when CL=2 is as following:

**Figure 24-19. SDRAM Read-to-Write access (CL=2)**

SDRAM read-to-write access timing when CL=3 is as following:

**Figure 24-20. SDRAM Read-to-Write access (CL=3)**

#### 24.5.6.3.4.3 SDRAM write-to-write access

SDRAM write-to-write access timing is as following:

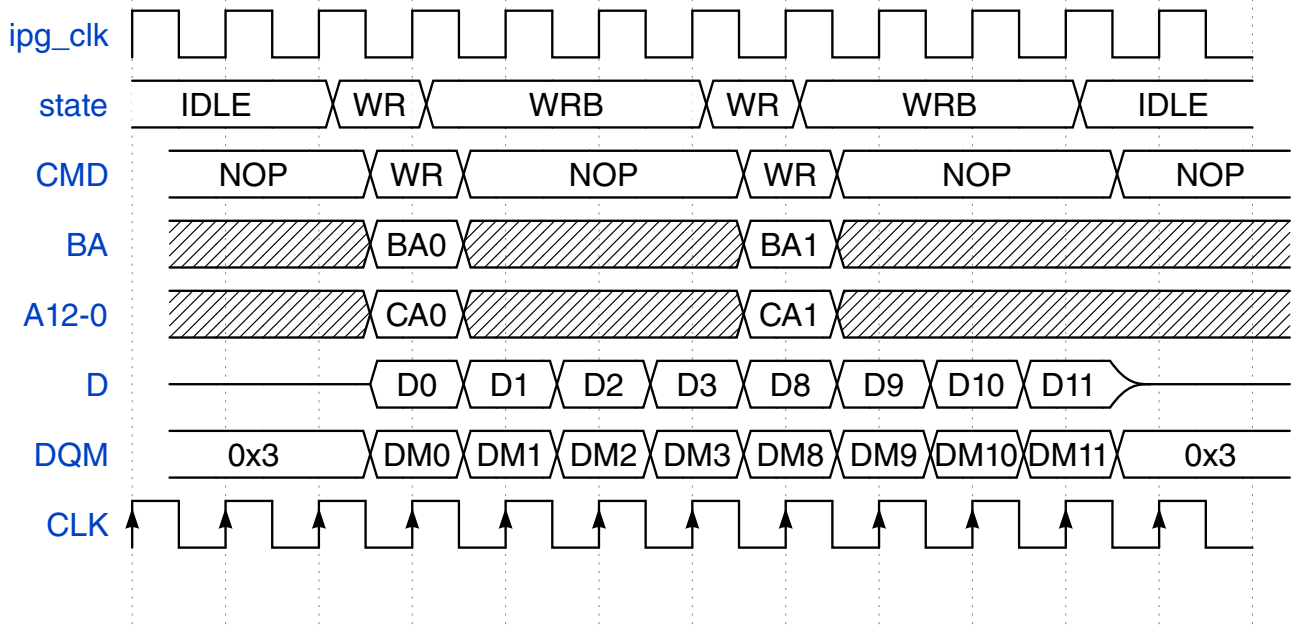

Figure 24-21. SDRAM Write-to-Write access

#### 24.5.6.3.4.4 SDRAM write-to-read access

SDRAM write-to-read access timing when CL=1 is as following:

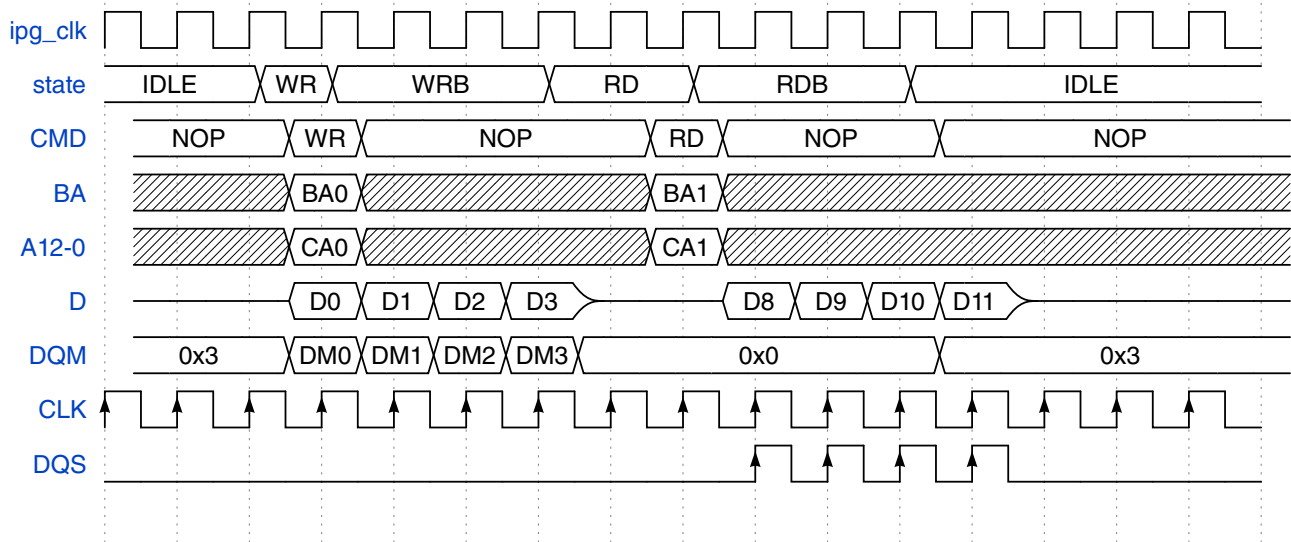

Figure 24-22. SDRAM Write-to-Read access (CL=1)

SDRAM write-to-read access timing when CL=2 is as following:

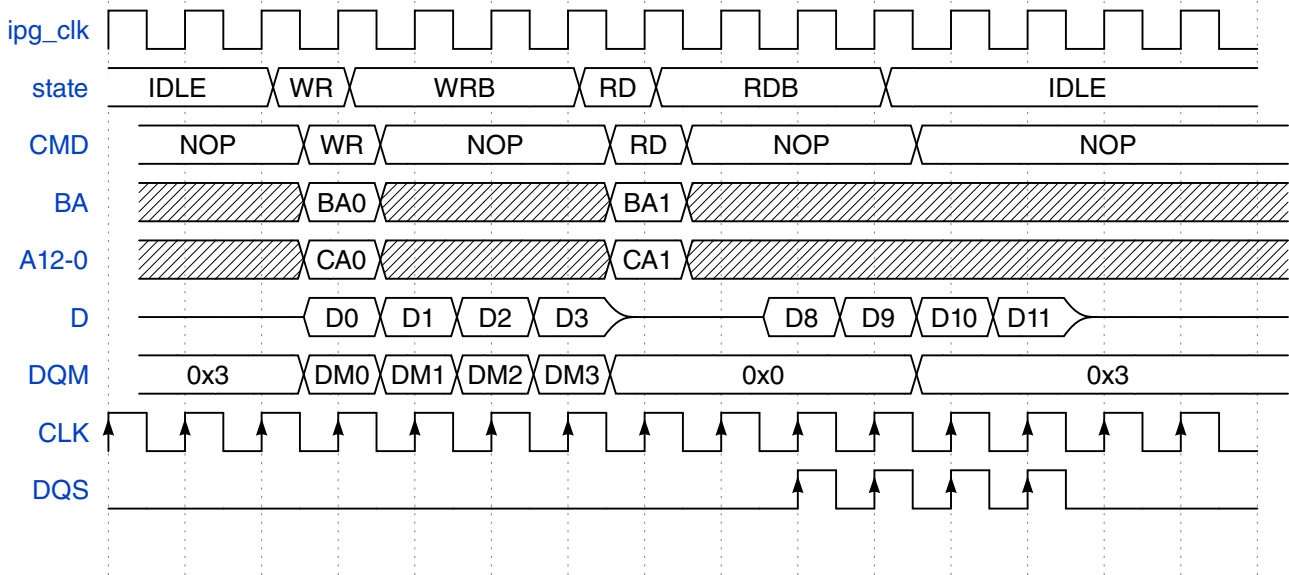

Figure 24-23. SDRAM Write-to-Read access (CL=2)

SDRAM write-to-read access timing when CL=3 is as following:

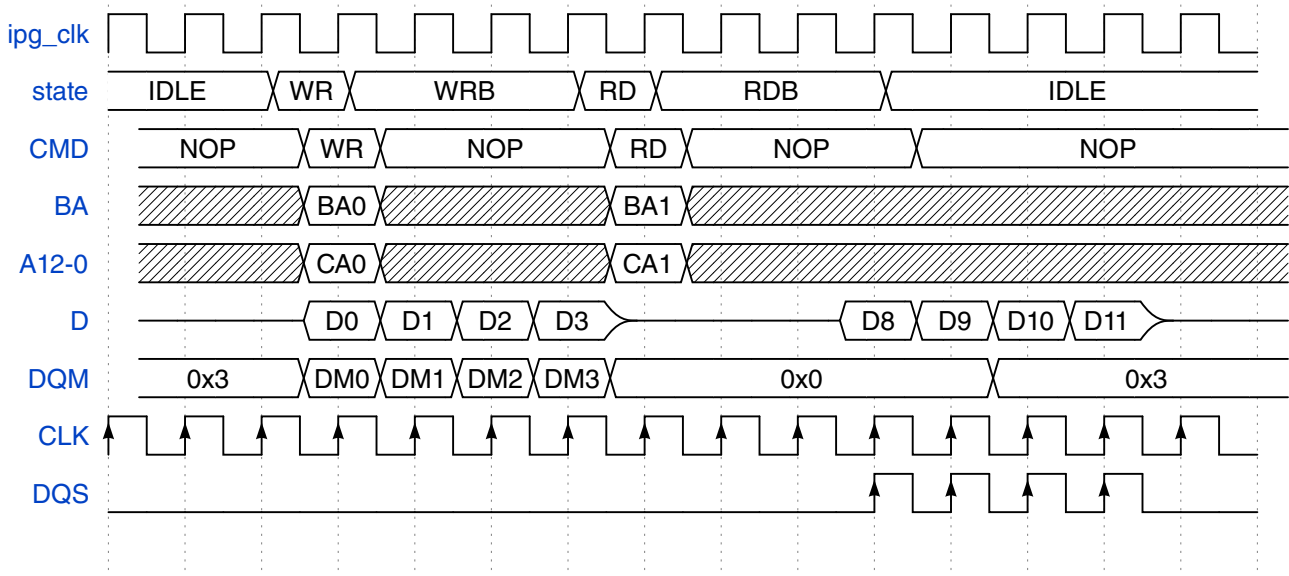

Figure 24-24. SDRAM Write-to-Read access (CL=3)

### 24.5.6.4 Refresh command - SDRAM AUTO Refresh

SEMC would send AUTO REFRESH command to all SDRAM devices when the refresh timer expired and SDRAM Refresh enabled (SDRAMCR3.REN=0x1). Multiple AUTO REFRESH command could be sent if refresh burst is not set to one (SDRAMCR3.REBL!=0x0).

Refresh command is triggered by interval refresh timer period.

Following timing diagram illustrates the sequence for Refresh Command.

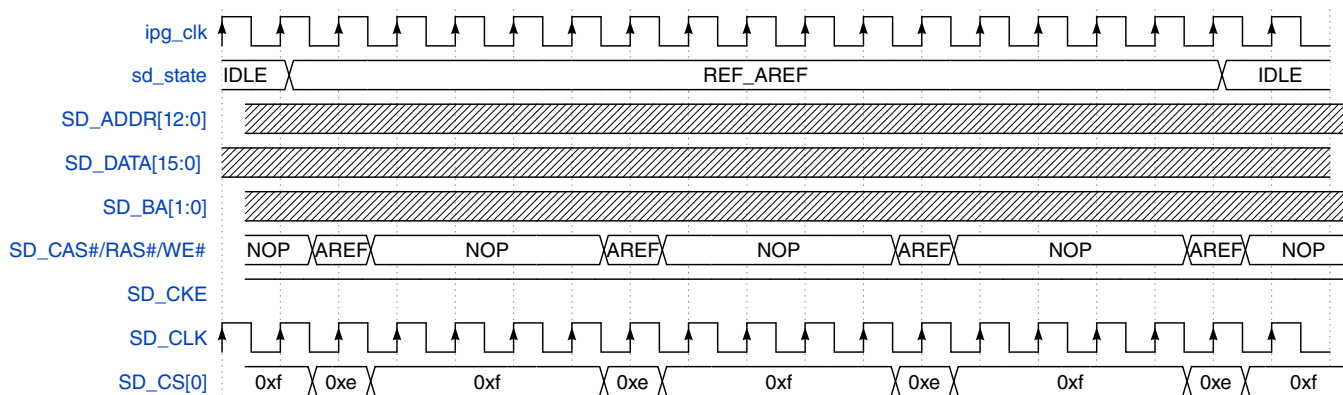

Figure 24-25. Refresh command - SDRAM Auto Refresh

### 24.5.6.5 SDRAM low power feature

This section describes the low power feature implemented for SDRAM.

#### 24.5.6.5.1 Stop mode - SDRAM

When system enter STOP mode, SEMC will put all SDRAM device into self refresh state automatically. When system exit STOP mode, SEMC will bring SDRAM device out from self refresh state.

Following timing diagram illustrates the sequence for stop mode entering and exiting.

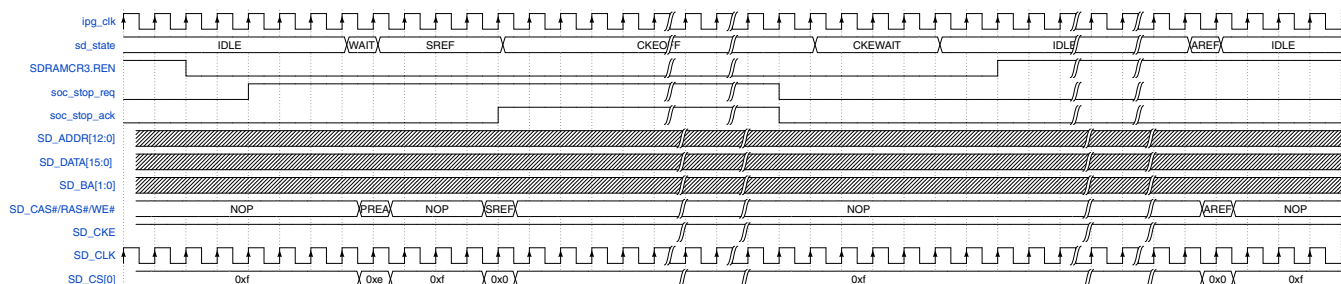

Figure 24-26. Stop mode Enter and Exit- SDRAM

### 24.5.6.5.2 BUS Idle - SDRAM

When there is no IP/AXI/Refresh command, SDRAM interface would be in IDLE state (NOP command and chip selection invalid). When SDRAM interface bus idle timer expired, SEMC will close all pages opened on all SDRAM devices. Please see xx for more detail about bus idle timer.

### 24.5.6.6 SDRAM Page Management

This section describes the SDRAM page management.

There are 8 pages row address saved internally: 4 pages for CS0/CS2 (4 bank), 4 pages for CS1/CS3 (4 bank). Device CS0 and CS2 page will never be opened at the same time. Before SEMC open pages on CS2, it will close all opened pages on CS0. This is similar for CS1/CS3.

SEMC close all pages on all CS in following cases:

1. SELF REFRESH triggered by IP command
2. SELF REFRESH triggered by stop mode enter
3. The idle time on AXI bus and SDRAM interface is longer than SDRAM idle timeout time (SDRAMCR2.ITO).

#### NOTE

SEMC will not sent out PRECHARGE-ALL command if there is no page opened on any bank/CS.

SEMC close all pages on one CS in following cases:

1. PRECHARGE ALL command triggered by IP command
2. AUTO REFRESH command triggered by IP command
3. ACTIVE/WRITE/READ command triggered by IP command and CS miss
4. WRITE/READ command triggered by current AXI command and CS miss

5. WRITE/READ command triggered by next AXI command (not accepted yet), CS miss and not same CS as current AXI command

### NOTE

One example for CS miss: Current IP command will access CS2 but there is page opened on CS0 already.

SEMC close one page on one CS in following cases:

1. PRECHARGE command triggered by IP command and this bank is opened
2. ACTIVE/READ/WRITE command triggered by IP command, this bank is opened and page missed.
3. WRITE/READ command triggered by current AXI command this bank is opened and page missed.
4. WRITE/READ command triggered by next AXI command (not accepted yet), this bank is opened, page missed and different bank accessed with current AXI command.

### NOTE

One example for page miss: current bank is opened but the opened page row address is different with current SDRAM command access.

SEMC open one page on one CS in following cases:

1. ACTIVE/READ/WRITE command triggered by IP command, this bank is not opened.
2. WRITE/READ command triggered by current AXI command this bank is not opened.
3. WRITE/READ command triggered by next AXI command (not accepted yet), this bank is not opened and different bank accessed with current AXI command.

### NOTE

One example for page miss: current bank is opened but the opened page row address is different with current SDRAM command access.

## 24.5.6.7 SDRAM Timers

This section describes the timers used for SDRAM operation

#### **24.5.6.7.1 Prescaler**

The prescaler timer in SDRAM controller count freely with the period defined by SDRAM3.PRESCALE. When the prescaler timer expired, urgent refresh timer and SDRAM BUS IDLE timer count by 1.

#### **24.5.6.7.2 Refresh interval timer**

The refresh interval timer also count when prescaler timer expires. The timer period is determined by SDRAMCR3.RT and SDRAMCR3.PRESCALE. When refresh interval timer expired, an internal refresh command will be triggered and SEMC will sent one or multiple AUTO REFRESH command on SDRAM interface.

#### **24.5.6.7.3 Urgent Refresh timer**

Urgent refresh timer is used to determine whether current refresh request is urgent or normal. Before urgent refresh timer timeout, refresh request is handled in lower priority than AXI/IP command. When urgent refresh timer timed out, refresh request becomes urgent. SDRAM controller will handle Auto-Refresh command in higher priority than AXI/IP command.

#### **24.5.6.7.4 Beat timer**

The beat timer is used to control SDRAM read/write/Auto Refresh command burst length.

#### **24.5.6.7.5 ACTIVE to READ/WRITE timer**

The ACTIVE to READ/WRITE timer is used to promise the minimum cycle number between ACITVE command and READ/WRITE command on SDRAM interface.

#### **24.5.6.7.6 PRECHARGE to ACTIVE timer**

The PRECHARGE to ACTIVE timer is used to promise the minimum cycle number between PRECHARGE/PRECHARGE ALL command and ACTIVE/AUTO REFRESH/SELF REFRESH command on SDRAM interface.

#### **24.5.6.7.7 CKE OFF timer**

The CKEOFF timer is used to promise the minimum cycle of SDRAM CLK off state.

#### **24.5.6.7.8 SELF REFRESH recover timer**

The SRRC timer is used to promise the wait time between SDRAM device exit Self Refresh state and sending new Commands to device. SDRAM device may have limitation on Self Refresh recovery time. Before this recovery time expire, any command to device may cause unexpected behavior.

#### **24.5.6.7.9 AUTO REFRESH recover timer**

The RFRC timer is used to promise the minimum cycle number between Auto Refresh command and ACTIVE command on SDRAM interface. SDRAM device may have limitation on Refresh recovery time. Before this recovery time expire, any command to device may cause unexpected behavior.

#### **24.5.6.7.10 Refresh to Refresh timer**

The refresh to refresh timer is used to promise the minimum cycle number between Auto Refresh command and Auto Refresh command on SDRAM interface.

#### **24.5.6.7.11 ACTIVE to ACTIVE timer**

There are two ACT2ACT timer in SDRAM controller. ACT2ACT0 timer is used to promise the minimum cycle number between ACTIVE command and ACTIVE command on CS0/2 device. ACT2ACT1 timer is used to promise the minimum cycle number between ACTIVE command and ACTIVE command on CS1/3 device.

#### **24.5.6.7.12 ACTIVE to PRECHARGE timer**

There are two ACT2PRE timer in SDRAM controller. ACT2PRE0 timer is used to promise the minimum cycle number between ACTIVE command and PRECHARGE/PRECHARGE ALL command on CS0/2 device. ACT2PRE1 timer is used to promise the minimum cycle number between ACTIVE command and PRECHARGE/PRECHARGE ALL command on CS1/3 device.

#### **24.5.6.7.13 Write recovery timer**

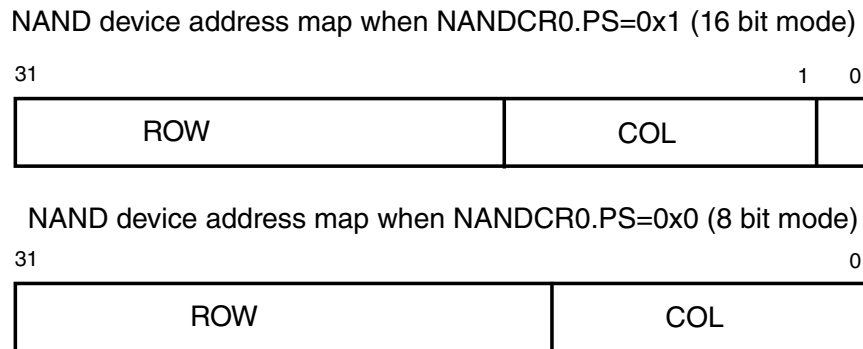

The WRC timer is used to promise the minimum cycle number between WRITE command and PRECHARGE/PRECHARGE ALL command on SDRAM interface. SDRAM device may have limitation on WRITE recovery time. Before this recovery time expire, PRECHARGE/PRECHARGE ALL command to device may cause the write process failed.

## 24.5.7 NAND Flash Controller Operations

This section describes the NAND Flash controller module's operations.

### 24.5.7.1 NAND Flash address map

NAND Flash device address map on SoC is indicated in the following diagram:

**Figure 24-27. NAND Flash Address Map**

### 24.5.7.2 NAND Flash access address type

There are 6 type address type access provided:

- One Byte Column address
- Two Byte Column address
- One Byte Row address
- Two Byte Row address
- Three Byte Row address
- Five Byte Row/Column address

For IP command, address type is determined by IPCMD register; For AXI command, address type is fixed to "Two Byte Column Address" because all NAND Flash access is in NAND page boundary.

#### 24.5.7.2.1 One Byte Column Address

One Byte column address type access is indicated as following:

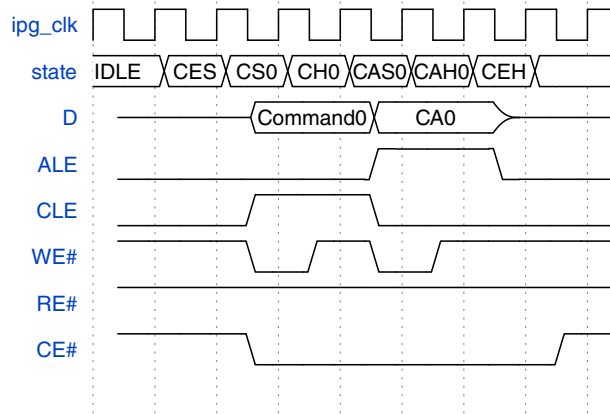

Figure 24-28. NAND Flash access Address type - One Byte Column Address

### 24.5.7.2.2 Two Byte Column Address

Two Byte column address type access is indicated as following:

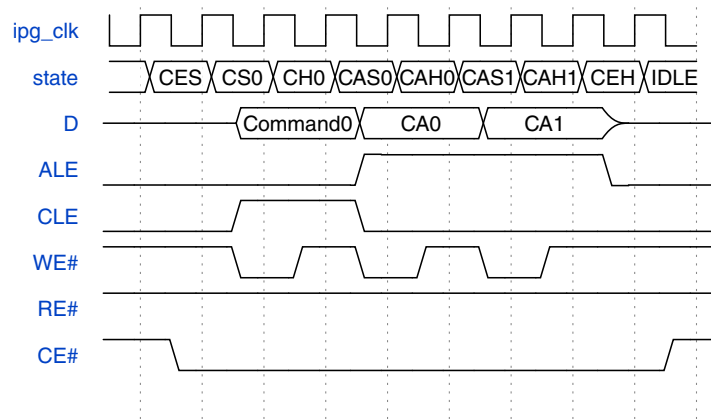

Figure 24-29. NAND Flash access Address type - Two Byte Column Address

### 24.5.7.2.3 One Byte Row Address

One Byte row address type access is indicated as following:

Figure 24-30. NAND Flash access Address type - One Byte Row Address

#### 24.5.7.2.4 Two Byte Row Address

Two Byte row address type access is indicated as following:

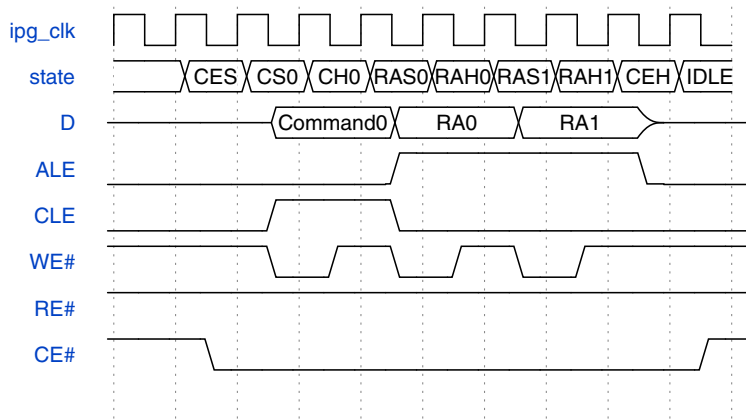

Figure 24-31. NAND Flash access Address type - Two Byte Row Address

#### 24.5.7.2.5 Three Byte Row Address

Three Byte row address type access is indicated as following:

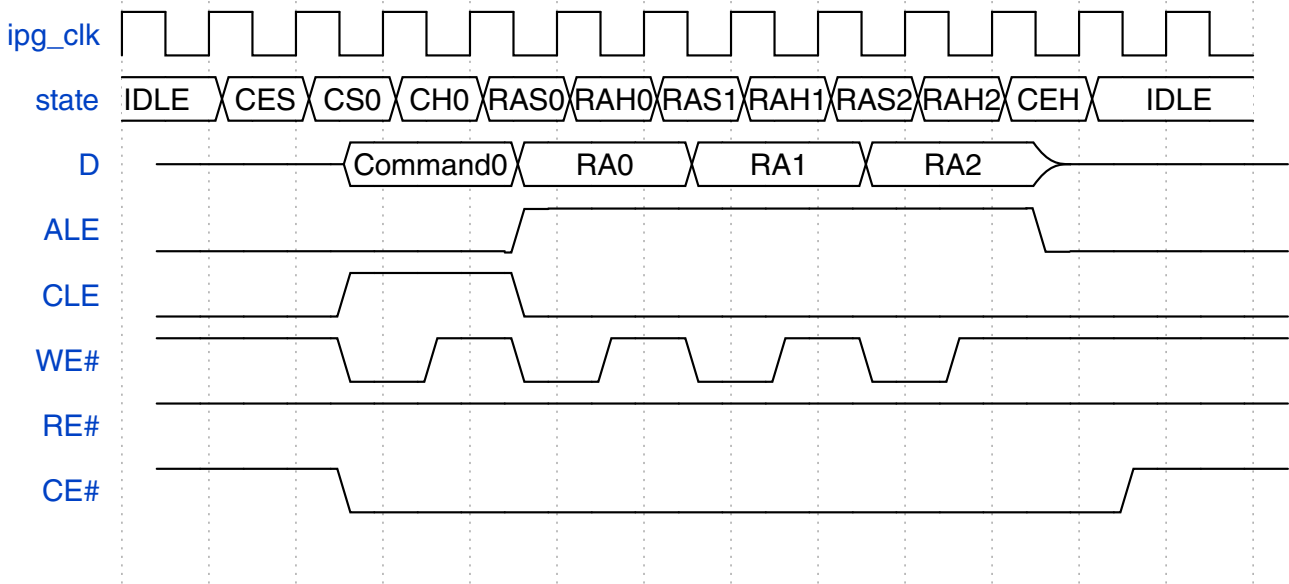

Figure 24-32. NAND Flash access Address type - Three Byte Row Address

### 24.5.7.2.6 Five Byte Row/Column Address

Five Byte row/column address type access is indicated as following:

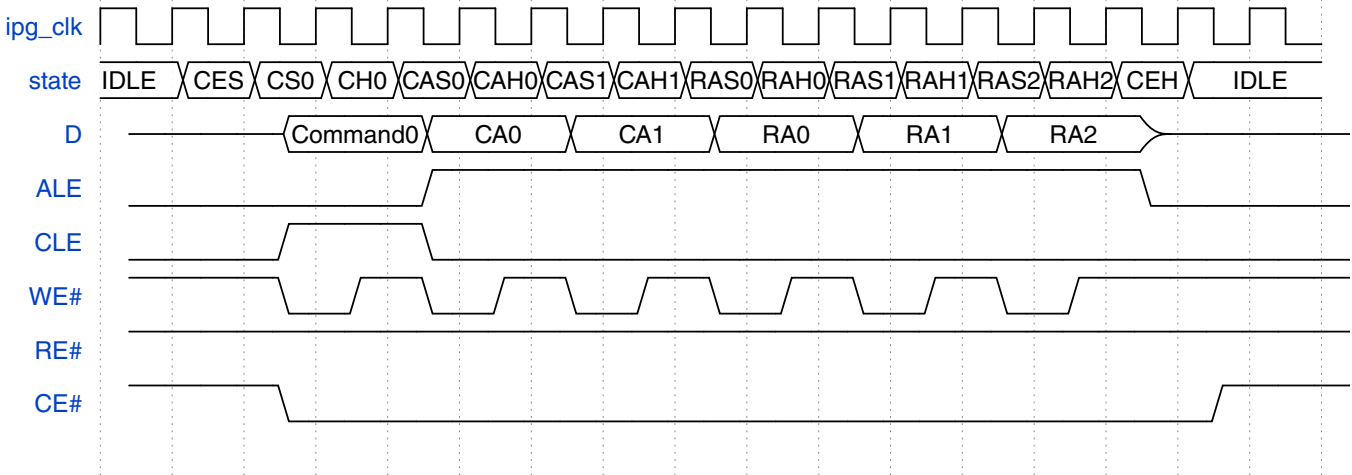

Figure 24-33. NAND Flash access Address type - Five Byte Row/Column Address

There are some option bits provide to support more NAND address type access. Five byte row/column address type could be overried as following:

Table 24-2. Address byte order for Row/Column Address five Byte mode

NDOPT3	NDOPT2	NDOPT1	Address byte order
0	0	0	CA0/CA1/RA0/RA1/RA2

Table continues on the next page...

**Table 24-2. Address byte order for Row/Column Address five Byte mode (continued)**

NDOPT3	NDOPT2	NDOPT1	Address byte order
0	0	1	CA0/RA0/RA1/RA2
0	1	0	CA0/CA1/RA0/RA1
0	1	1	CA0/RA0/RA1
1	-	0	CA0/CA1/RA0
1	-	1	CA0/RA0

### 24.5.7.3 NAND Flash access command type

NAND Flash access support following command types:

1. Command Phase Only
2. Command + Wait Phase
3. Command + Address Phase
4. Command + Address + Wait Phase
5. Command + Address + Read Phase
6. Command + Address + Write Phase (For IP command)
7. Command + Write Phase
8. Command + Read Phase
9. Write Phase Only
10. Read Phase Only
11. Command + Address + Command + Read Phase (For AXI command - Read)
12. Command + Address + Write Phase (For AXI command - Write)

#### 24.5.7.3.1 Command Phase Only

NAND Flash Command Phase Only access is indicated as following:

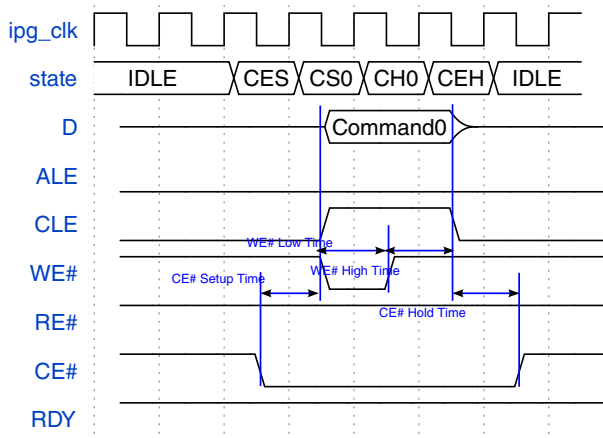

Figure 24-34. NAND Flash access command type - Command Phase Only

### 24.5.7.3.2 Command + Wait Phase

NAND Flash Command + Wait Phase access is indicated as following:

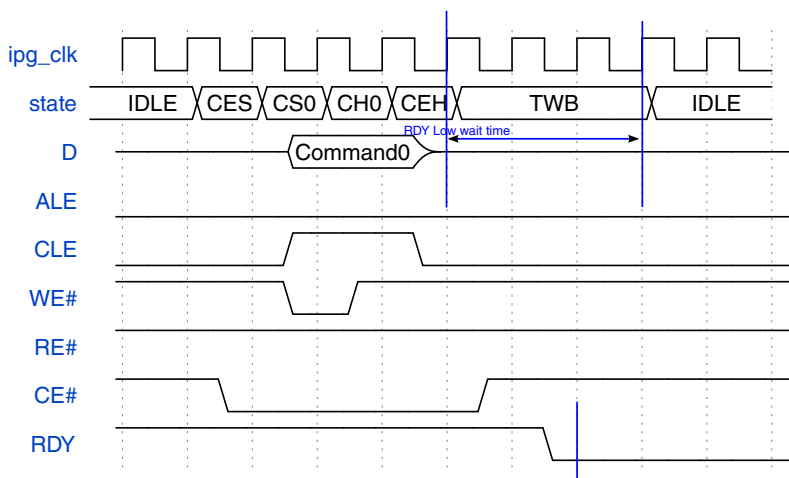

Figure 24-35. NAND Flash access command type - Command + Wait Phase

### 24.5.7.3.3 Command + Address Phase

NAND Flash Command + Address Phase access is indicated as following:

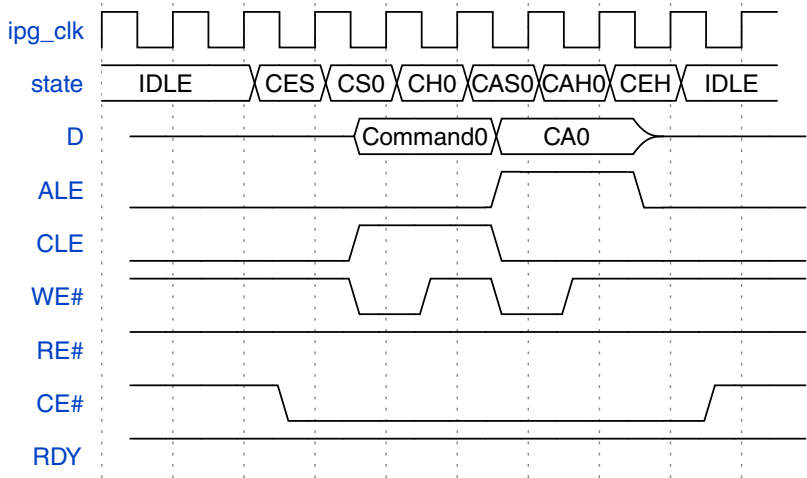

Figure 24-36. NAND Flash access command type - Command + Address Phase

### 24.5.7.3.4 Command + Address + Wait Phase

NAND Flash Command + Address + Wait Phase access is indicated as following:

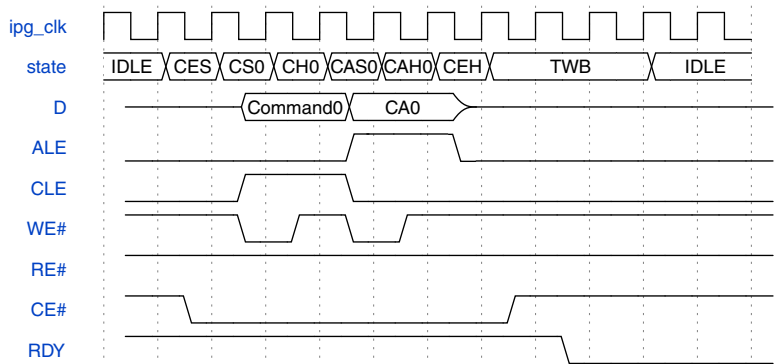

Figure 24-37. NAND Flash access command type - Command + Address + Wait Phase

### 24.5.7.3.5 Command + Address + Read Phase

NAND Flash Command + Address + Read Phase access is indicated as following:

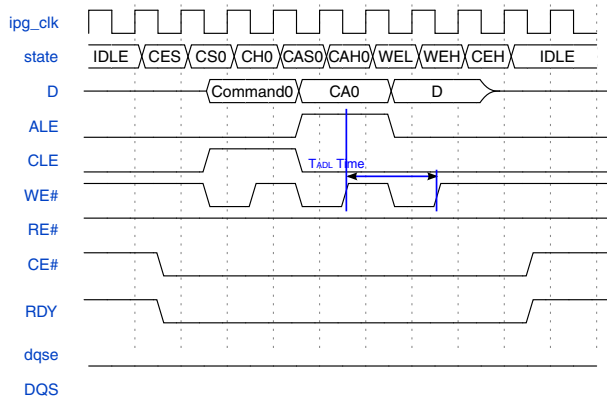

**Functional description**

**Figure 24-38. NAND Flash access command type - Command + Address + Read Phase**

**24.5.7.3.6 Command + Address + Write Phase (For IP command)**

NAND Flash Command + Address + Write Phase access is indicated as following:

**Figure 24-39. NAND Flash access command type - Command + Address + Write Phase**

**24.5.7.3.7 Command + Read Phase**

NAND Flash Command + Read Phase access is indicated as following:

Figure 24-40. NAND Flash access command type - Command + Read Phase

### 24.5.7.3.8 Command + Write Phase

NAND Flash Command + Write Phase access is indicated as following:

Figure 24-41. NAND Flash access command type - Command + Write Phase

### 24.5.7.3.9 Read Phase Only

NAND Flash Read Phase Only access is indicated as following:

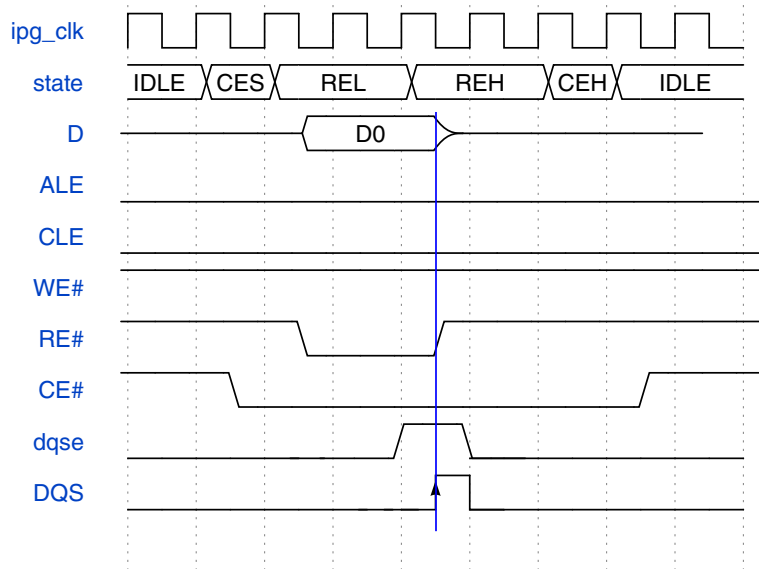

Figure 24-42. NAND Flash access command type - Read Phase Only

### 24.5.7.3.10 Write Phase Only

NAND Flash Write Phase Only access is indicated as following:

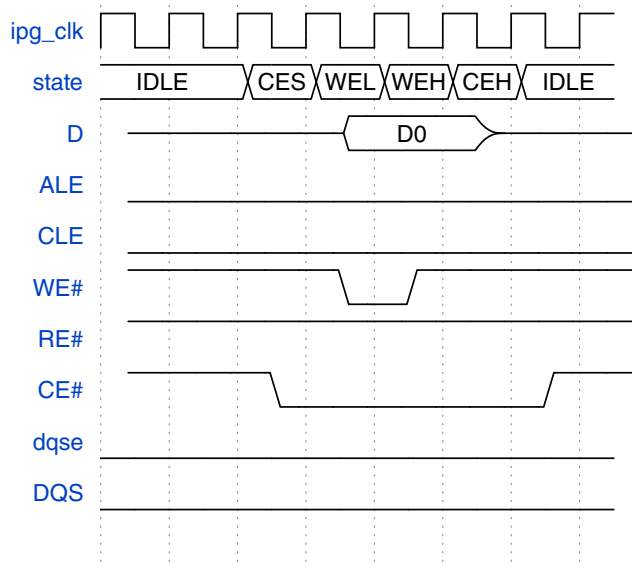

Figure 24-43. NAND Flash access command type - Write Phase Only

### 24.5.7.3.11 Command + Address + Command + Read Phase

NAND Flash Command + Address + Command + Read Phase access is indicated as following:

Figure 24-44. NAND Flash access command type - Command + Address + Command + Read Phase

### 24.5.7.3.12 Command + Address + Write Phase (For AXI command)

NAND Flash Command + Address + Write Phase access is indicated as following:

Figure 24-45. NAND Flash access command type - Command + Address + Write Phase

### 24.5.7.4 NAND Flash read access EDO and non-EDO mode

NAND Flash read access could be done in EDO or non-EDO mode. The timing indicated as following:

Figure 24-46. NAND Flash Read Access in EDO or non-EDO mode

## 24.5.8 NOR Flash Controller Operations

This section describes the NOR Flash controller module's operations.

### 24.5.8.1 NOR Flash Read Operation in ASYNC Mode

Flash read operation in ASYNC mode is indicated in following diagrams:

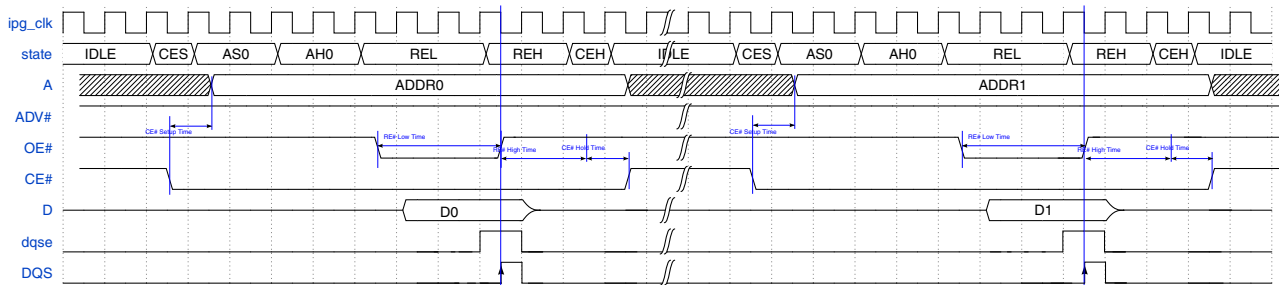

Figure 24-47. Flash Read in ASYNC mode (Non-ADMUX)

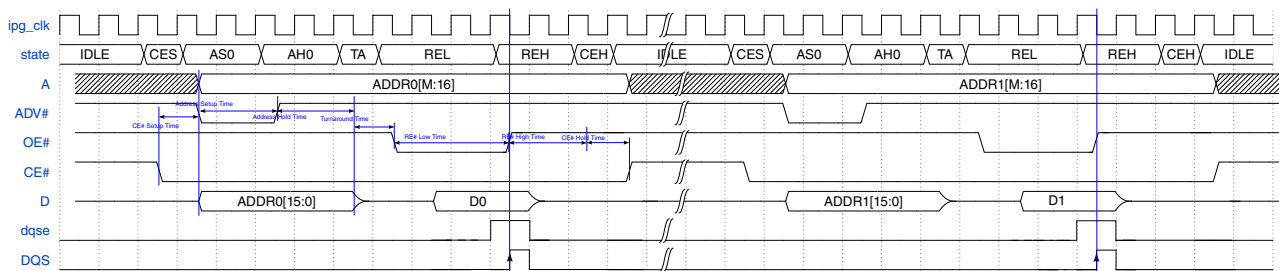

Figure 24-48. Flash Read in ASYNC mode (ADMUX)

Figure 24-49. Flash Read in ASYNC mode (AADM)

### 24.5.8.2 NOR Flash Write Operation in ASYNC mode

Flash write operation in ASYNC mode is indicated in following diagrams:

Figure 24-50. Flash Write in ASYNC mode (Non-ADMUX)

Figure 24-51. Flash Write in ASYNC mode (ADMUX)

Figure 24-52. Flash Write in ASYNC mode (AADM)

### 24.5.8.3 NOR Flash Read Operation in SYNC mode

Flash read operation in SYNC mode is indicated in following diagrams:

Functional description

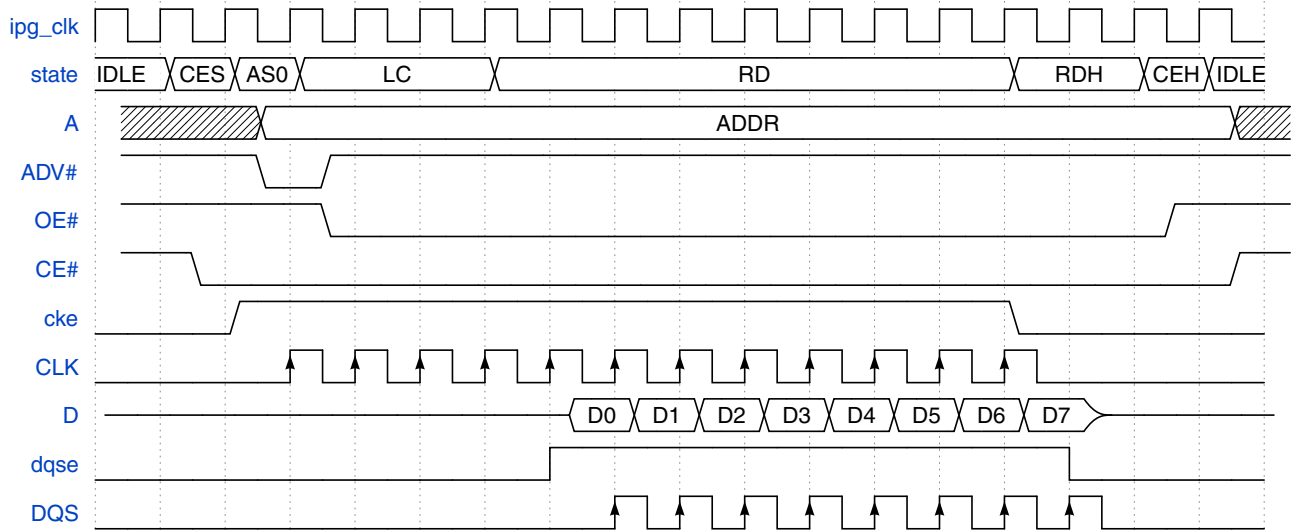

Figure 24-53. Flash Read in SYNC mode (Non-ADMUX)

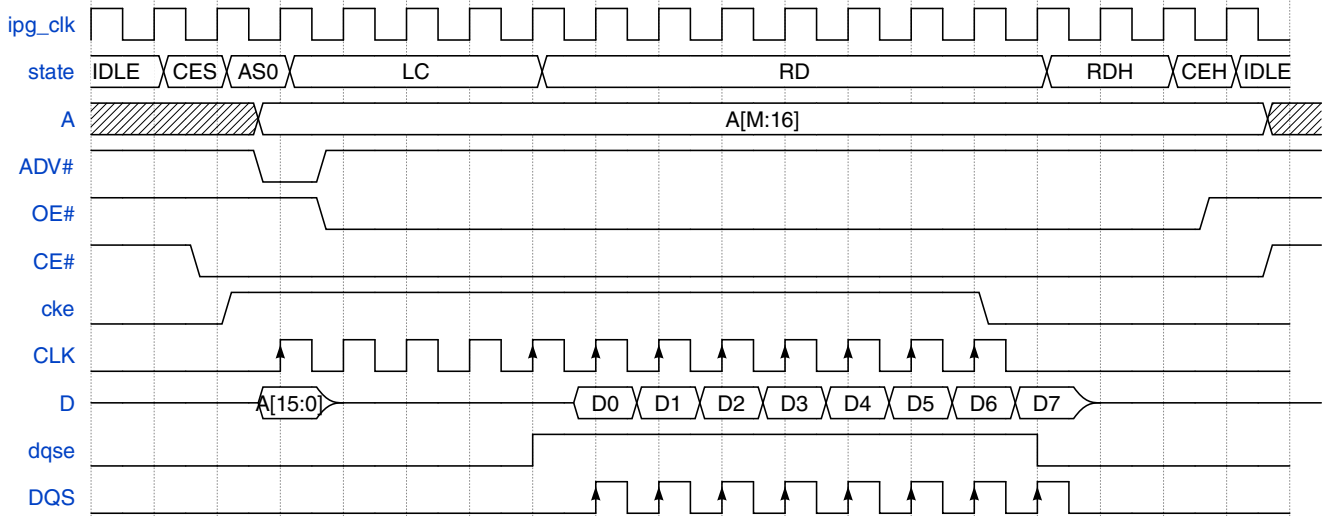

Figure 24-54. Flash Read in SYNC mode (ADMUX)

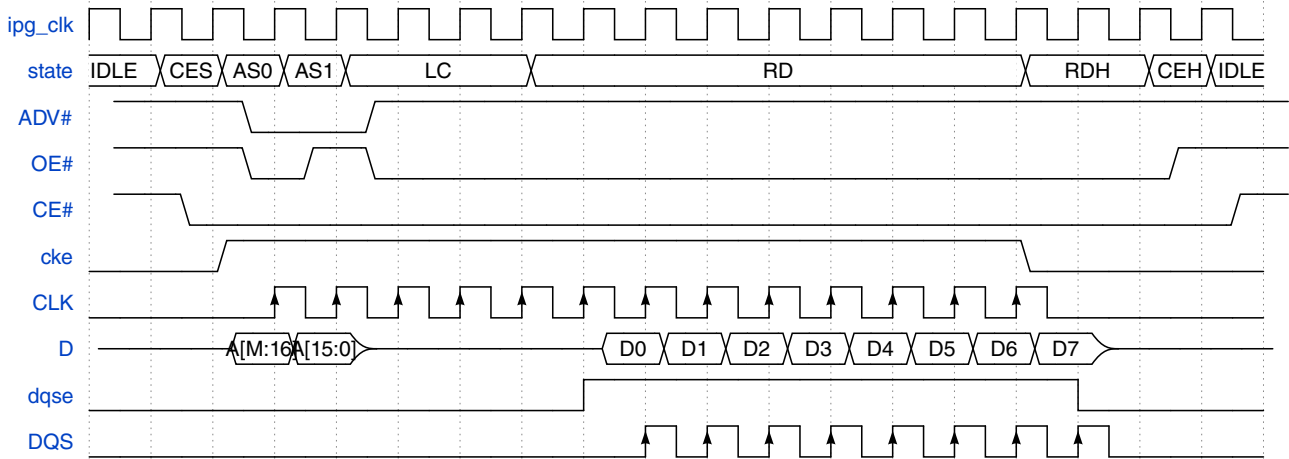

Figure 24-55. Flash Read in SYNC mode (AADM)

## 24.5.9 SRAM Controller Operations

This section describes the SRAM controller module's operations.

### 24.5.9.1 SRAM Read Operation in ASYNC Mode

SRAM read operation in ASYNC mode is indicated in following diagrams:

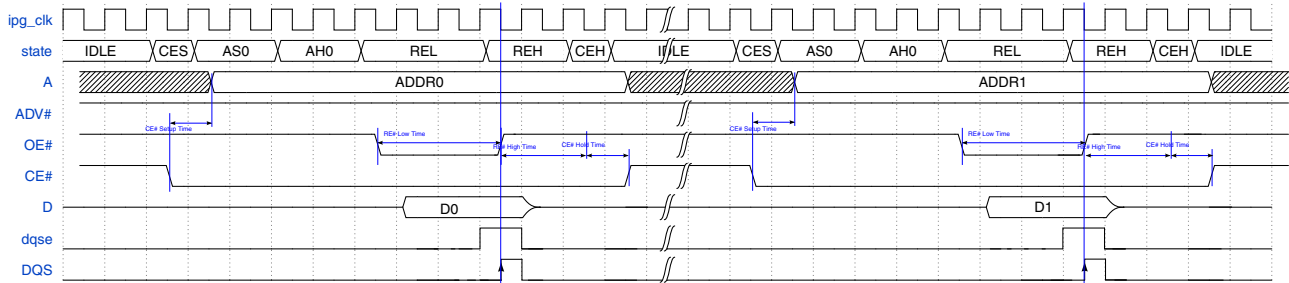

Figure 24-56. SRAM Read in ASYNC mode (Non-ADMUX)

## Functional description

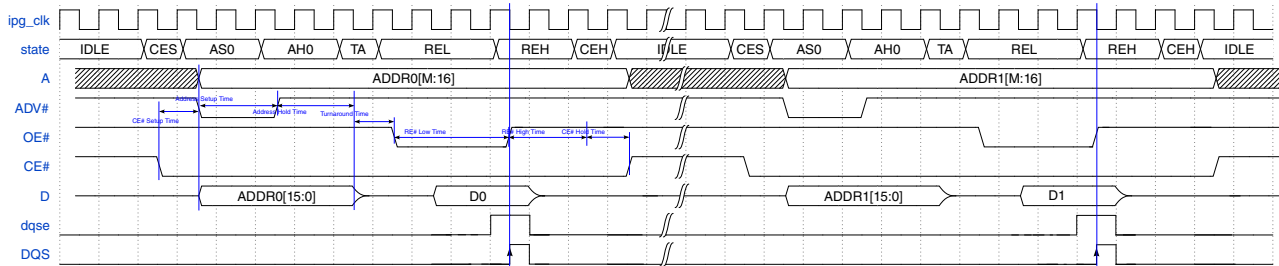

Figure 24-57. SRAM Read in ASYNC mode (ADMUX)

Figure 24-58. SRAM Read in ASYNC mode (AADM)

## 24.5.9.2 SRAM Write Operation in ASYNC mode

SRAM write operation in ASYNC mode is indicated in following diagrams:

Figure 24-59. SRAM Write in ASYNC mode (Non-ADMUX)

Figure 24-60. SRAM Write in ASYNC mode (ADMUX)

Figure 24-61. SRAM Write in ASYNC mode (AADM)

### 24.5.9.3 SRAM Read Operation in SYNC mode

SRAM read operation in SYNC mode is indicated in following diagrams:

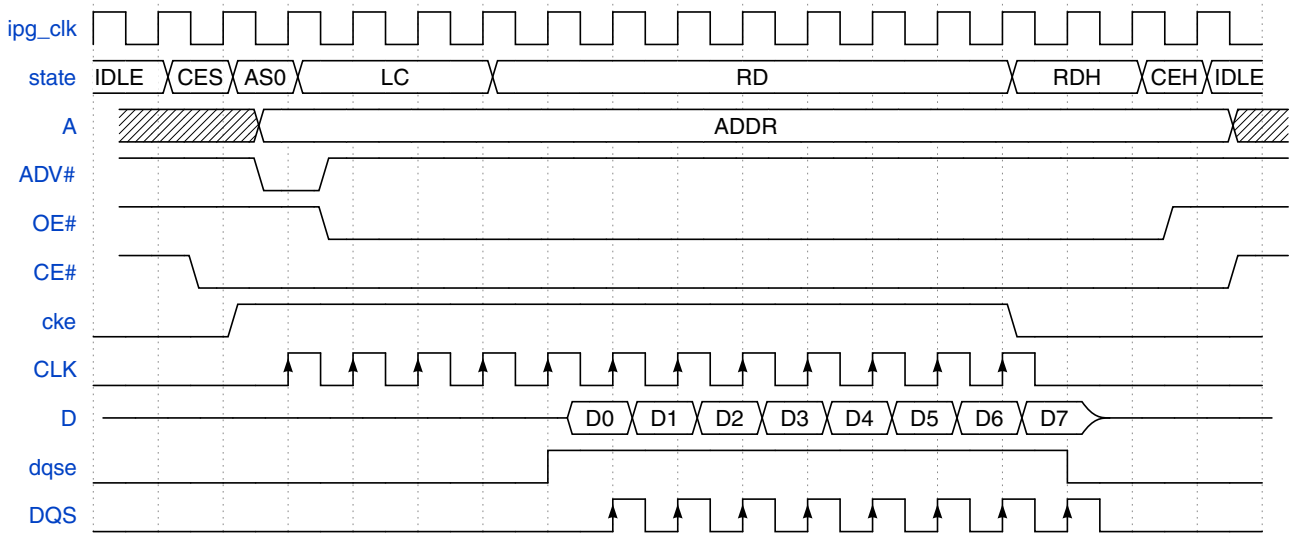

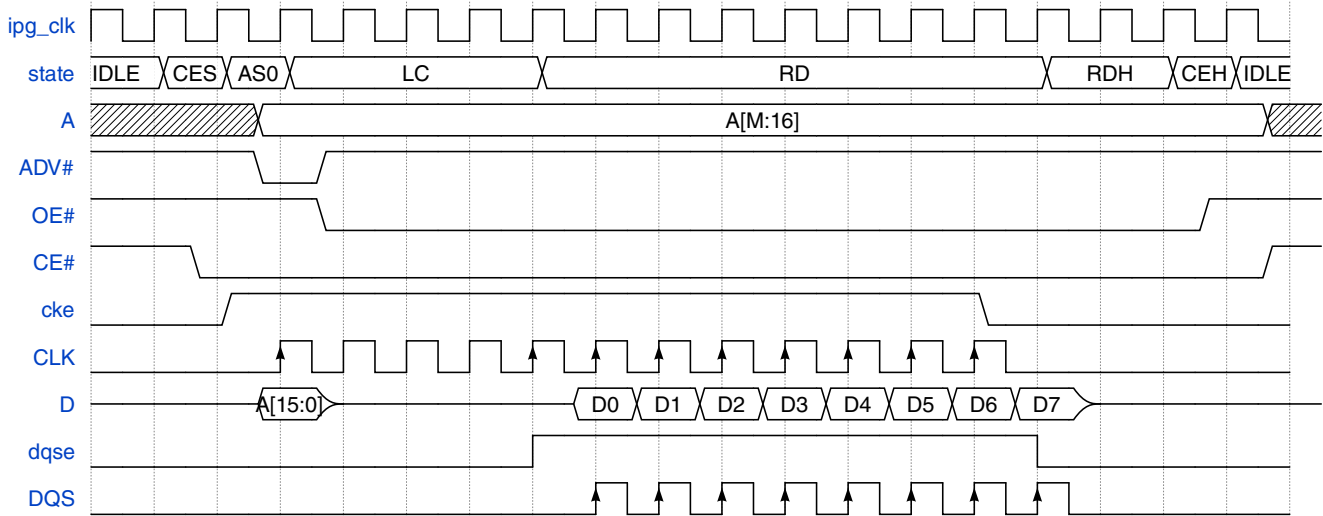

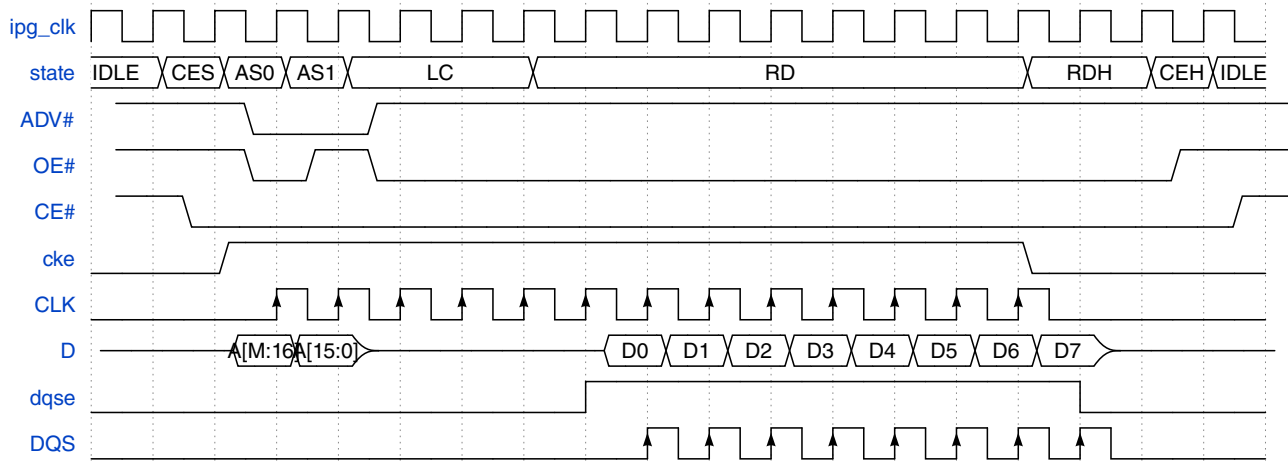

Figure 24-62. SRAM Read in SYNC mode (Non-ADMUX)

## Functional description

**Figure 24-63. SRAM Read in SYNC mode (ADMUX)**

**Figure 24-64. SRAM Read in SYNC mode (AADM)**

### 24.5.9.4 SRAM Write Operation in SYNC mode

SRAM write operation in SYNC mode is indicated in following diagrams:

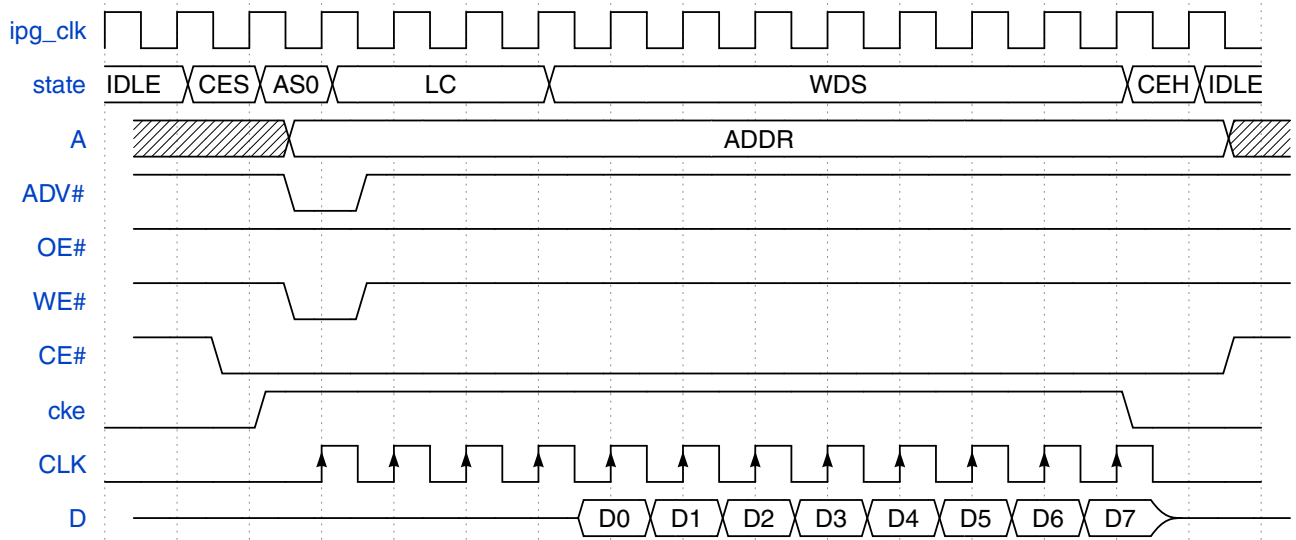

Figure 24-65. SRAM Write in SYNC mode (Non-ADMUX)

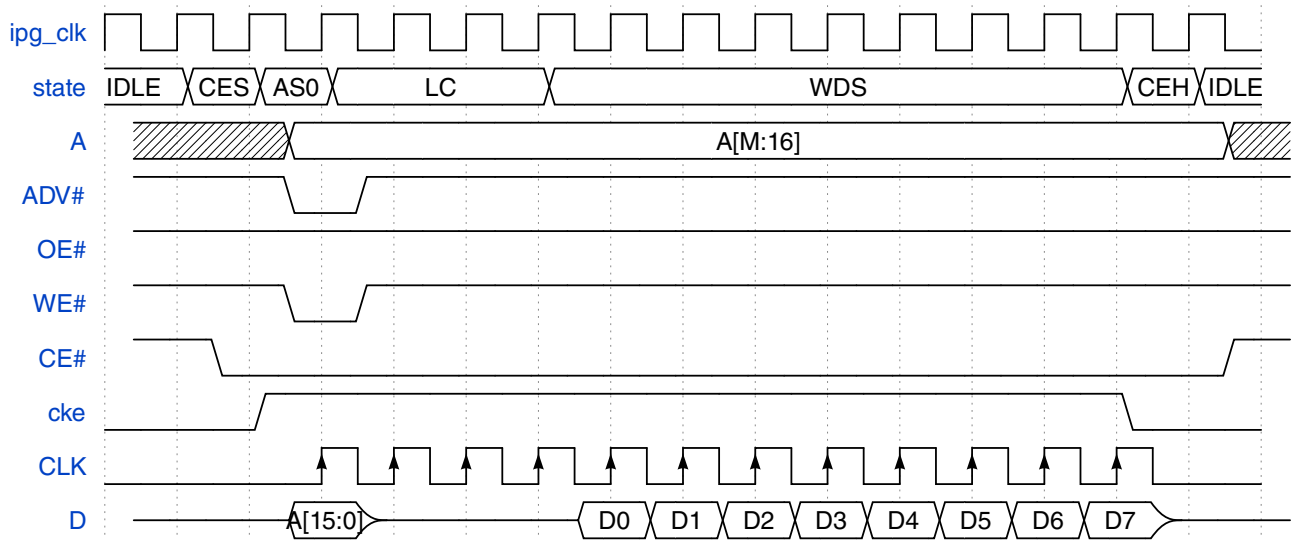

Figure 24-66. SRAM Write in SYNC mode (ADMUX)

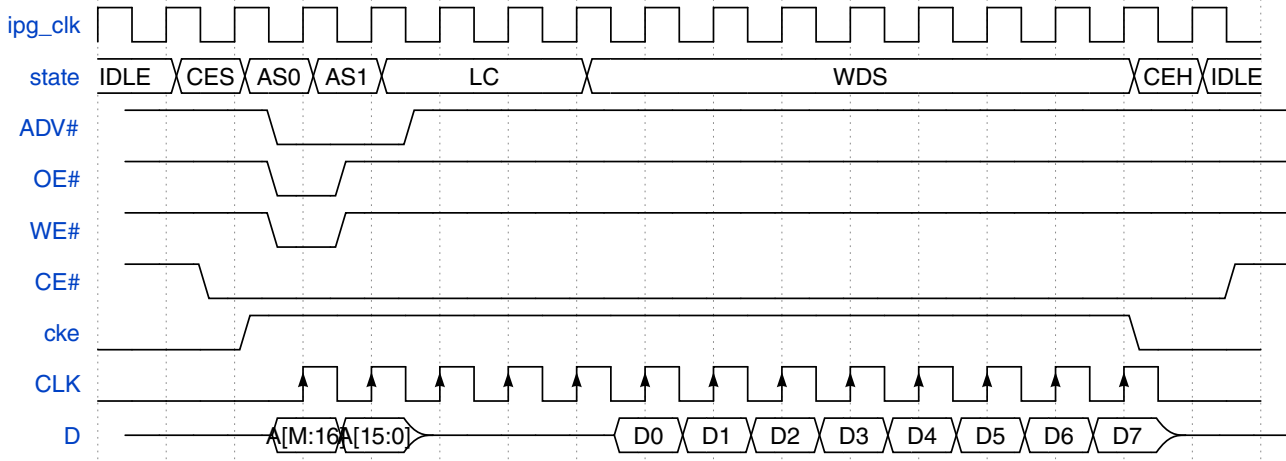

Figure 24-67. SRAM Write in SYNC mode (AADM)

### 24.5.10 Display Bus Interface Controller Operations

DBI read/write operation indicated as following.

Figure 24-68. DBI Read/Write operation

#### NOTE

- For read access to DBI, it always handled as DBI DATA READ transaction
- For write access to DBI, it will be handled as DBI COMMAND WRITE transaction if address is higher than 0x10000 (with DBI Base address removed). Otherwise, it will be handled as DBI DATA WRITE transaction.
- DBI address is not sent to device at all. Only used to determine DBI COMMAND or DATA WRITE.
- DBI bus never sent out address information for COMMAND WRITE, DATA WRITE and DATA READ command.
- AXI WRAP write access to DBI is supported.

- AXI WRAP read access to DBI is not supported except when the first beat address offset is zero in the burst.
- DBI bus interface doesn't support WRITE MASK feature.
- All write strobe in AXI write access to DBI should be valid (one). If AXI write strobe is invalid(zero), SEMC will send write data 8'h00 instead of original write data.
- When DBI bus is 16 bit (DBICR0.PS=0x1), AXI command or IP command access (both read and write) start address to DBI bus should be 16 bit aligned. Otherwise the read data is unknown or the write data to DBI may be wrong. There will be no bus error response or internal error status generated.

# Chapter 25

## Ultra Secured Digital Host Controller (uSDHC)

### 25.1 Chip-specific uSDHC information

Table 25-1. Reference links to related information

Topic	Related module(s)	Reference
System memory map	-	<a href="#">System Memory Map</a>
Clocking	CCM	<a href="#">Clock Management</a> <a href="#">Clock Control Module (CCM)</a>
Power management	PMU	<a href="#">Power Management</a> <a href="#">Power Management Unit</a>
Signal multiplexing	IOMUX	<a href="#">External Signals and Pin Multiplexing</a> <a href="#">IOMUX</a>
Interrupts, DMA Events and XBAR Assignments	-	<a href="#">Interrupts, DMA Events and XBAR Assignments</a>

On this device, for data transfer modes, uSDHC1 only supports 1-bit and 4-bit modes, while uSDHC2 can support 1-bit, 4-bit and 8-bit modes.

#### NOTE

HS400 mode is not supported on this device.

### 25.2 Overview

The Ultra Secured Digital Host Controller (uSDHC) provides the interface between the host system and the SD/SDIO/MMC cards, as depicted in [Figure 25-1](#).

The uSDHC acts as a bridge, passing host bus transactions to the SD/SDIO/MMC cards by sending commands and performing data accesses to/from the cards.

It handles the SD/SDIO/MMC protocols at the transmission level.

The following are brief descriptions of the cards supported by the uSDHC:

The Multi Media Card (MMC) is a universal low cost data storage and communication media designed to cover a wide array of applications including mobile video and gaming. Previous MMC cards were based on a 7-pin serial bus with a single data pin, while the new high speed MMC communication is based on an advanced 11-pin serial bus designed to operate in the low voltage range.

The Secure Digital Card (SD) is an evolution of the old MMC technology. It is specifically designed to meet the security, capacity, performance, and environment requirements inherent in newly-emerging audio and video consumer electronic devices. The physical form factor, pin assignment and data transfer protocol are forward-compatible with the old MMC (with some additions).

Under the SD protocol, it can be categorized into Memory card, I/O card and Combo card, which has both memory and I/O functions. The memory card invokes a copyright protection mechanism that complies with the security of the SDMI standard. The I/O card, which is also known as SDIO card, provides high-speed data I/O with low power consumption for mobile electronic devices. For the sake of simplicity, the following figure does not show cards with reduced size or mini cards.

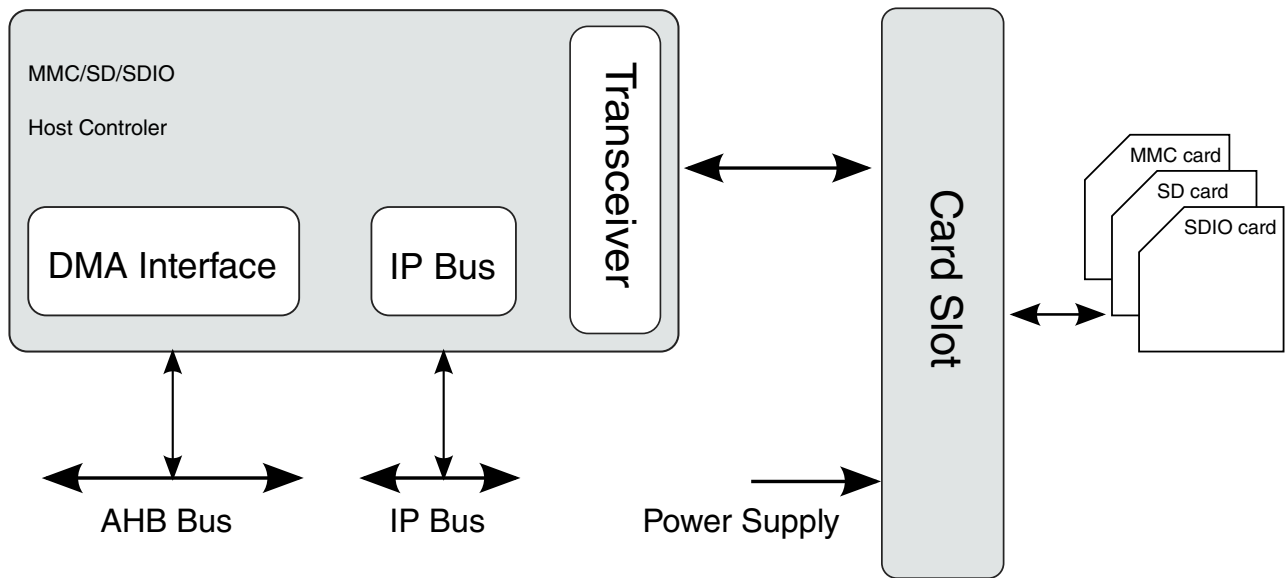

Figure 25-1. System Connection of the uSDHC

Figure 25-2. ultra Secure Digital Host Controller Block Diagram

## 25.2.1 Features

The features of the uSDHC module include the following:

- Conforms to the SD Host Controller Standard Specification version 2.0/3.0
- Compatible with the MMC System Specification version 4.2/4.3/4.4/4.41/4.5
- Compatible with the SD Memory Card Specification version 3.0 and supports the Extended Capacity SD Memory Card
- Compatible with the SDIO Card Specification version 2.0/3.0
- Designed to work with SD Memory, miniSD Memory, SDIO, miniSDIO, SD Combo, MMC, MMC plus, and MMC RS cards
- Card bus clock frequency up to 208 MHz
- Supports 1-bit / 4-bit SD and SDIO modes, 1-bit / 4-bit / 8-bit MMC modes
  - Up to 832 Mbps of data transfer for SDIO cards using 4 parallel data lines in SDR(Single Data Rate) mode
  - Up to 400 Mbps of data transfer for SDIO card using 4 parallel data lines in DDR(Dual Data Rate) mode
  - Up to 832 Mbps of data transfer for SDXC cards using 4 parallel data lines in SDR(Single Data Rate) mode
  - Up to 400 Mbps of data transfer for SDXC card using 4 parallel data lines in DDR(Dual Data Rate) mode
  - Up to 1600 Mbps of data transfer for MMC cards using 8 parallel data lines in SDR(Single Data Rate) mode
  - Up to 832 Mbps of data transfer for MMC cards using 8 parallel data lines in DDR(Dual Data Rate) mode
- Supports single block/multi-block read and write
- Supports block sizes of 1 ~ 4096 bytes
- Supports the write protection switch for write operations
- Supports both synchronous and asynchronous abort
- Supports pause during the data transfer at block gap
- Supports SDIO Read Wait and Suspend Resume operations
- Supports Auto CMD12 for multi-block transfer
- Host can initiate non-data transfer command while data transfer is in progress
- Allows cards to interrupt the host in 1-bit and 4-bit SDIO modes, also supports interrupt period
- Embodies a fully configurable 128x32-bit FIFO for read/write data
- Supports internal DMA capabilities
- Support voltage selection by configuring vendor specific register bit
- Supports Advanced DMA to perform linked memory access

Note: IP can support the above listed speed mode and max data throughput. For SOC, speed mode and data throughput should be specific to chip. See the corresponding chip description for details.

## 25.2.2 Modes and Operations

### 25.2.2.1 Data transfer Modes

The uSDHC can select the following modes for data transfer:

- SD 1-bit
- SD 4-bit
- MMC 1-bit
- MMC 4-bit
- MMC 8-bit
- Identification Mode (up to 400 kHz)
- MMC full speed mode (up to 26 MHz)
- MMC high speed mode (up to 52 MHz)
- MMC HS200 mode (up to 200 MHz)
- MMC DDR mode (52 MHz both edges)
- SD/SDIO full speed mode (up to 25 MHz)
- SD/SDIO high speed mode (up to 50 MHz)
- SD/SDIO UHS-I mode (up to 208 MHz in SDR mode, up to 50 MHz in DDR mode)

Note: IP can support the above-listed speed mode and max clock frequency. For SOC, speed mode and max clock frequency should be specific to chip. See the corresponding chip description for details.

## 25.3 External Signals

The following table describes the external signals of uSDHC:

**Table 25-2. uSDHC External Signals**

Signal	Description	Direction
CLK	Clock for MMC/SD/SDIO card	O
CMD	CMD line connect to card	I/O
DATA7	DAT7 line in 8-bit mode Not used in other modes	I/O

*Table continues on the next page...*

Table 25-2. uSDHC External Signals (continued)

Signal	Description	Direction
DATA6	DAT6 line in 8-bit mode Not used in other modes	I/O
DATA5	DAT5 line in 8-bit mode Not used in other modes	I/O
DATA4	DAT4 line in 8-bit mode Not used in other modes	I/O
DATA3	DAT3 line in 4/8-bit mode or configured as card detection pin May be configured as card detection pin in 1-bit mode	I/O
DATA2	DAT2 line or Read Wait in 4-bit mode Read Wait in 1-bit mode	I/O
DATA1	DAT1 line in 4/8-bit mode Also used to detect interrupt in 1/4-bit mode	I/O
DATA0	DAT0 line in all modes Also used to detect busy state	I/O
CD_B	Card detection pin If not used(for the embedded memory),tie low to indicate there is a card attached.	I
WP	Card write protect detect If not used(for the embedded memory), tie low to indicate it's not write protected.	I
LCTL	LED control used to drive an external LED Active high Fully controlled by the driver Optional output	O
RESET_B	Card hardware reset signal, active LOW	O
VSELECT	IO power voltage selection signal	O

### 25.3.1 Signals Overview

The uSDHC has 14 associated I/O signals.

- The CLK is an internally generated clock used to drive the MMC, SD, SDIO cards.
- The CMD I/O is used to send commands and receive responses to and from the card. Eight data lines (DAT7~DAT0) are used to perform data transfers between the uSDHC and the card.
- The CD and WP are card detection and write protection signals directly routed from the socket. These two signals are active low (0). A low on CD\_B means that a card is inserted, and a high on WP means that the write protect switch is active.

- LCTL is an output signal used to drive an external LED to indicate that the SD interface is busy.
- RST is an output signal used to reset the MMC card.
- VSELECT is an output signal used to change the voltage of the external power supplier.

CD, WP, LCTL, RST and VSELECT are all optional for system implementation. If the uSDHC needs to support a 4-bit data transfer, DAT7~DAT4 can also be optional and tied to high. If the uSDHC does not support HS400 mode, STROBE can also be optional and tied to low.

## 25.4 Clocks

The table found here describes the clock sources for uSDHC.

**Table 25-3. uSDHC Clocks**

Clock name	Clock Root	Description
hclk	ahb_clk_root	AHB bus clock
ipg_clk	ipg_clk_root	Peripheral clock
ipg_clk_perclk	usdhc_clk_root	Base clock
ipg_clk_s	ipg_clk_root	Peripheral access clock for register accesses

## 25.5 Functional Description

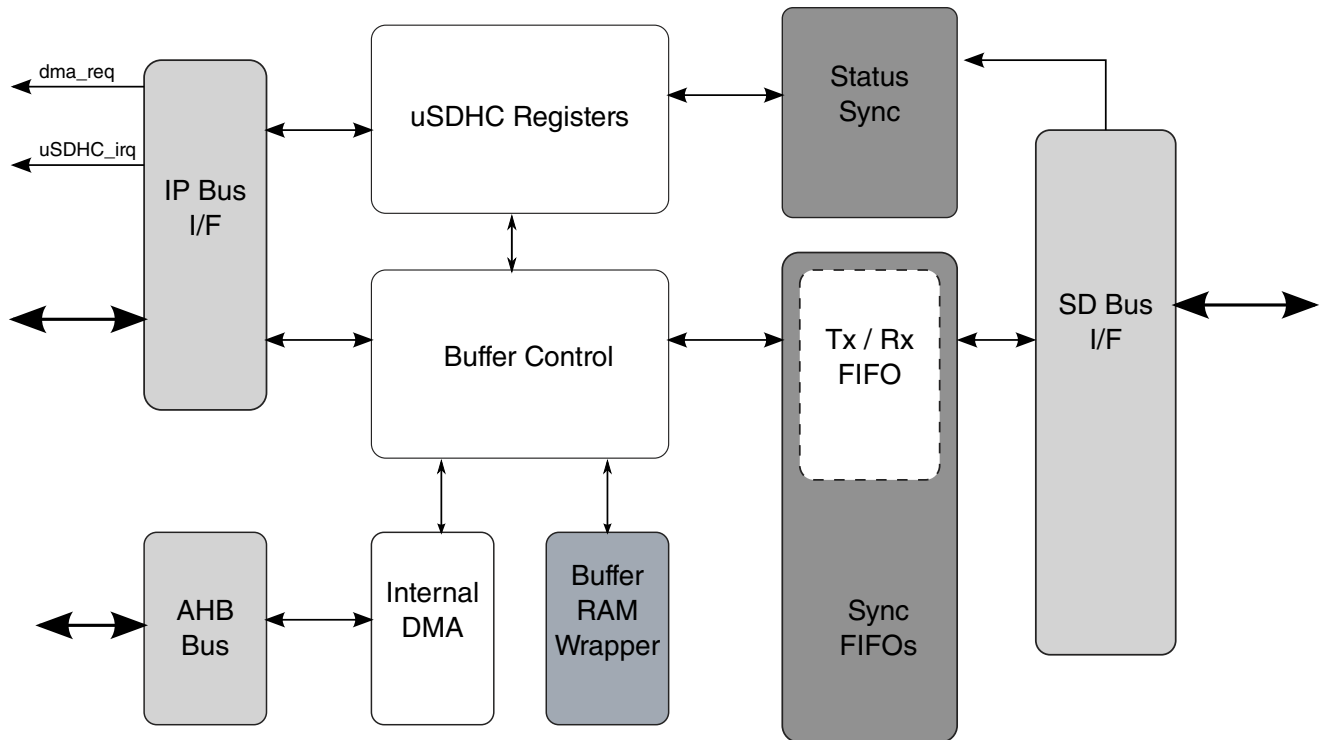

The following sections provide a brief functional description of the major system blocks, including the Data Buffer, DMA AHB interface, register bank as well as IP Bus interface, dual-port memory wrapper, data/command controller, clock & reset manager and clock generator.

### 25.5.1 Data Buffer

The uSDHC uses one configurable data buffer to transfer data between the system bus (IP Bus or AHB Bus) and the SD card in an optimized manner, maximizing throughput between the two clock domains (IP peripheral clock and the master clock).

## Functional Description

The buffer is used as temporary storage for data being transferred between the host system and the card. The watermark levels for read and write are both configurable and can be from 1 to 128 words. The burst lengths for read and write are also configurable and can be from 1 to 31 words.

**Figure 25-3. uSDHC Buffer Scheme**

There are 2 transfer modes to access the data buffer:

- CPU polling mode:
  - For a host read operation, when the number of words received in the buffer meets or exceeds the `RD_WML` watermark value, by polling the `BRR` bit, the Host Driver can read the Buffer Data Port register to fetch the amount of words set in the `RD_WML` register from the buffer. The write operation is similar.
- Internal DMA mode (includes simple and advanced DMA accesses):
  - The internal DMA access, either by simple or advanced DMA, is over the AHB bus.

For a read operation, when there are more words in the buffer than the amount set in the `RD_WML` register, the internal DMA starts fetching data over the AHB bus. Except for `INCR4` and `INCR8`, the burst type is always `INCR` mode and the burst length depends on the shortest of following factors:

- Burst length configured in the burst length field of the Watermark Level register
- Watermark Level boundary

- Block size boundary
- Data boundary configured in the current descriptor (if the ADMA is active)
- 1 Kbyte address boundary defined in the AHB protocol

Write operation is similar.

Sequential and contiguous access is necessary to ensure the pointer address value is correct. Random or skipped access is not possible. The byte order, by reset, is little endian mode. The actual byte order is swapped inside the buffer, according to the endian mode configured by software (see the following figures). For a host write operation, byte order is swapped after data is fetched from the buffer and ready to send to the SD Bus. For a host read operation, byte order is swapped before the data is stored in the buffer.

**Figure 25-4. Data Swap between System Bus and uSDHC Data Buffer in Byte Little Endian Mode**

**Figure 25-5. Data Swap between System Bus and uSDHC Data Buffer in Half Word Big Endian Mode**

### 25.5.1.1 Write Operation Sequence

There are 2 ways to write data into the buffer when the user transfers data to the card:

- Processor core polling through the BWR bit in Interrupt Status register (interrupt or polling)
- Internal DMA

When the internal DMA is not used, (the DMAEN bit in the Transfer Type register is not set when the command is sent), the uSDHC asserts a DMA request when the amount of buffer space exceeds the value set in the WR\_WML register, and is ready for receiving new data. At the same time, the uSDHC sets the BWR bit. The buffer write ready interrupt will be generated if it is enabled by software.

When internal DMA is used, the uSDHC will not inform the system before all the required number of bytes are transferred (if no error was encountered). When an error occurs during the data transfer, the uSDHC will abort the data transfer and abandon the current block. The Host Driver should read the contents of the DMA System Address register to obtain the starting address of the abandoned data block. If the current data transfer is in multi-block mode, the uSDHC will not automatically send CMD12, even though the AC12EN bit in the Transfer Type register is set. The Host Driver sends CMD12 in this scenario and re-starts the write operation from that address. It is recommended that a Software Reset for Data be applied before the transfer is re-started.

The uSDHC will not start data transmission until the number of words set in the WR\_WML register can be held in the buffer. If the buffer is empty and the Host System does not write data in time, the uSDHC will stop the CLK to avoid the data buffer under-run situation.

### **25.5.1.2 Read Operation Sequence**

There are 2 ways to read data from the buffer when the user transfers data to the card:

- Processor core polling through the BRR bit in Interrupt Status register (interrupt or polling)
- Internal DMA

When internal DMA is not used (DMAEN bit in Transfer Type register is not set when the command is sent), the uSDHC asserts a DMA request when the amount of data exceeds the value set in the RD\_WML register, that is available and ready for system fetching data. At the same time, the uSDHC sets the BRR bit. The buffer read ready interrupt will be generated if it is enabled by software.

When internal DMA is used, the uSDHC will not inform the system before all the required number of bytes are transferred (if no error was encountered). When an error occurs during the data transfer, the uSDHC will abort the data transfer and abandon the current block. The Host Driver should read the content of the DMA System Address register to get the starting address of the abandoned data block. If the current data transfer is in multi-block mode, the uSDHC will not automatically send CMD12, even though the

AC12EN bit in the Transfer Type register is set. The Host Driver sends CMD12 in this scenario and re-starts the read operation from that address. It is recommended that a Software Reset for Data be applied before the transfer is re-started.

For any write transfer mode, the uSDHC will not start data transmission until the number of words set in the RD\_WML register are in the buffer. If the buffer is full and the Host System does not read data in time, the uSDHC will stop the CLK to avoid the data buffer over-run situation.

### 25.5.1.3 Data Buffer and Block Size

The user needs to know the buffer size for the buffer operation during a data transfer to utilize it in the most optimized way. In the uSDHC, the only data buffer can hold up to 128 words (32-bit) and the watermark levels for write and read can be configured accordingly.

For both read and write, the watermark level can be from 1 to 128 words. For both read and write the burst length can be from 1 to 31 words. The Host Driver may configure the value according to the system situation and requirement.

During a multi-block data transfer, the block length can be set to any value between 1 and 4096 bytes, satisfying the requirements of the external card. The only restriction is from the external card, which can be limited in size or support of a partial block access (which is not the integer times of 512 bytes).

As uSDHC treats each block individually, for block sizes which are not multiples of four (not word-aligned) stuffed bytes are required at the end of each block. For example, if the block size is 7 bytes and there are 12 blocks to write, the system side must write two times for each block. For each block the ending byte will be abandoned by uSDHC because it only sends 7 bytes to the card and picks data from the following system write, resulting in 24 beats of write access in total.

### 25.5.1.4 Dividing Large Data Transfer

This SDIO command CMD53 definition limits the maximum data size of data transfers according to the following formula:

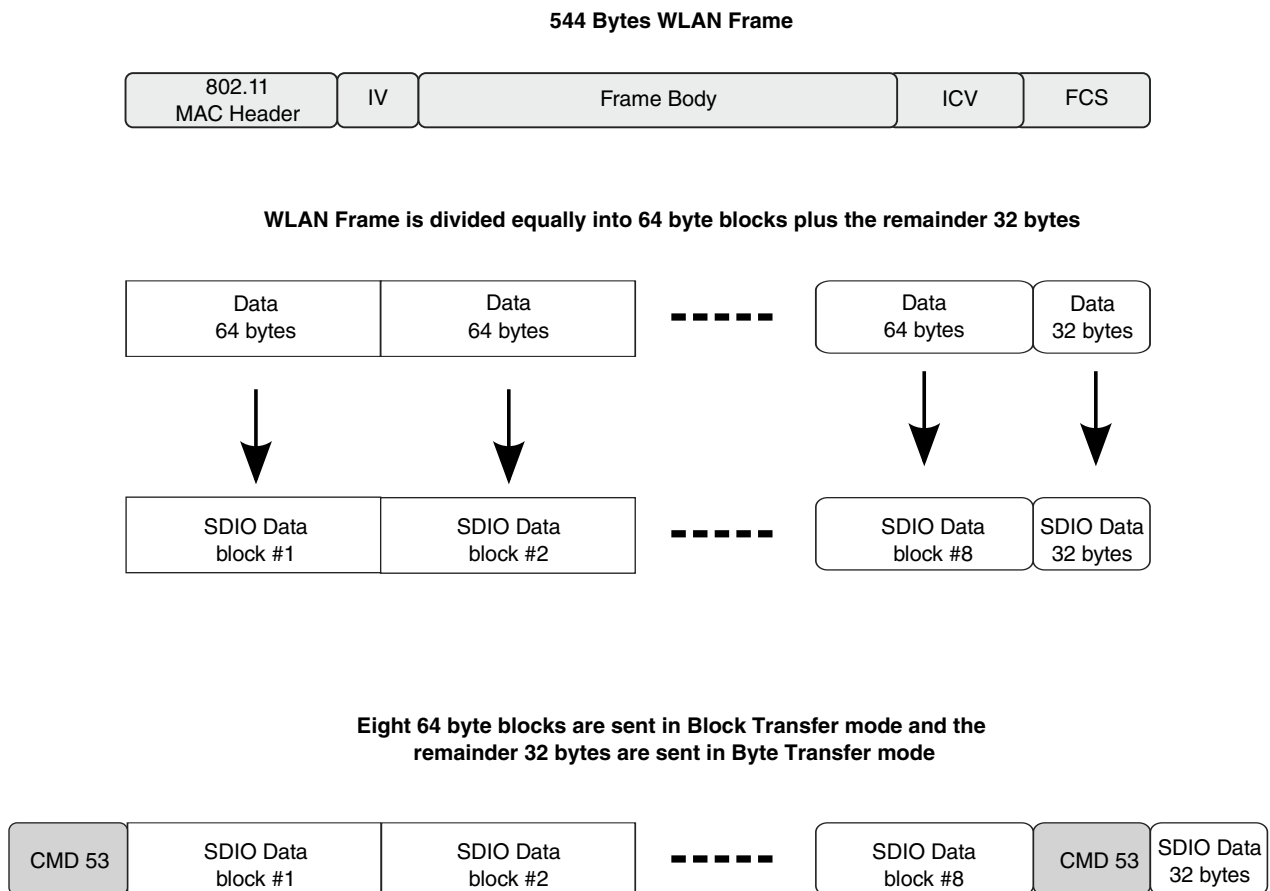

Max data size = Block size x Block count

The length of a multiple block transfer needs to be in block size units. If the total data length can't be divided evenly into a multiple of the block size, then there are two ways to transfer the data which depend on the function and the card design. Option 1 is for the Host Driver to split the transaction. The remainder of the block size data is then

## Functional Description

transferred by using a single block command at the end. Option 2 is to add dummy data in the last block to fill the block size. For option 2, the card must manage the removal of the dummy data.

See the figure below for an example showing the dividing of large data transfers, assuming a kind of WLAN SDIO card that only supports a block size up to 64 bytes. Although the uSDHC supports a block size of up to 4096 bytes, the SDIO can only accept a block size less than 64 bytes, so the data must be divided (see example below).

**Figure 25-6. Example for Dividing Large Data Transfers**

## 25.5.2 DMA AHB Interface

The internal DMA implements a DMA engine and the AHB master. When the internal DMA is enabled, the uSDHC\_dreq\_b will not be asserted during the transfer, but the BWR and BRR bits will be set if the BWRSEN and BRRSEN bits have been set in the Interrupt Status Enable register.

See the figure below for an illustration of the DMA AHB interface block.

Figure 25-7. DMA AHB Interface Block

### 25.5.2.1 Internal DMA Request

If the watermark level requirement is met in data transfer or if the last data of current block is ready in the data buffer, and the Internal DMA is enabled, the Data Buffer block will send a DMA request to AHB interface.

The delay in response from the internal DMA engine depends on the system AHB bus loading and the priority assigned to the uSDHC. The DMA engine does not respond to the request during its burst transfer, but is ready to serve as soon as the burst is over. The Data Buffer de-asserts the request if the data buffer space (for write) or bytes in data buffer is smaller than the watermark level. Upon access to the buffer by internal DMA, the Data Buffer updates its internal buffer pointer, and when the watermark level is satisfied or the last data of current block is ready in the data buffer, another DMA request is sent.

The data transfer is in the block unit, and the subsequent watermark level is always set as the remaining number of words. For instance, for a multi block data read with each block size of 31 bytes, and the burst length set to 6 words. After the first burst transfer, if there are more than 2 words in the buffer (which might contain some data of the next block), another DMA request is sent. This is because the remaining number of words to send for the current block is  $(31 - 6 * 4) / 4 = 2$ . The uSDHC will read 2 words out of the buffer, with 7 valid bytes and 1 stuffed byte.

### **25.5.2.2 DMA Burst Length**

Just like a CPU polling access, the DMA burst length for the internal DMA engine can be from 1 to 16 words. The actual burst length for the DMA depends on the lesser of the configured burst length or the remaining words of the current block.

See the example in [Internal DMA Request](#). After 6 words are read, the burst length will be 2 words, then the next burst length will be 6 words. This is because the next block starts, which is 31 bytes, more than 6 words. The Host Driver may take this variable burst length into account. It is also acceptable to configure the burst length as the divisor of the block size, so that each time the burst length will be the same.

### **25.5.2.3 AHB Master Interface**

It is possible that the internal AHB DMA engine could fail during the data transfer. Upon detection of an AHB bus error during DMA transfer, the DMA engine stops the transfer and goes to the idle state. At that point, the internal data buffer stops receiving incoming data and sending out data. The DMAE bit in the Interrupt Status register will be generated to host CPU to report a bus error condition.

Once the DMAE interrupt is received, the software shall send a CMD12 to abort the current transfer and read the DS\_ADDR bits of the DMA System Address register to get the starting address of the corrupted block. After the DMA error is fixed, the software should apply a data reset and re-start the transfer from this address to recover the corrupted block. DMA operation will resume when the interrupt is serviced by software.

### **25.5.2.4 ADMA Engine**

In the SD Host Controller Standard, a new DMA transfer algorithm called the ADMA (Advanced DMA) is defined. For Simple DMA, once the page boundary is reached, a DMA interrupt will be generated and the new system address shall be programmed by the Host Driver.

The ADMA defines the programmable descriptor table in the system memory. The Host Driver can calculate the system address at the page boundary and program the descriptor table before executing ADMA. It reduces the frequency of interrupts to the host system. Therefore, higher speed DMA transfers could be realized since the Host MCU intervention would not be needed during long DMA based data transfers.

There are two types of ADMA: ADMA1 and ADMA2 in Host Controller. ADMA1 can support data transfer of 4KB aligned data in system memory. ADMA2 improves the restriction so that data of any location and any size can be transferred in system memory. Their formats of Descriptor Table are different.

ADMA can recognize all kinds of descriptors define in SD Host Controller Standard, and if 'End' flag is detected in the descriptor, ADMA will stop after this descriptor is processed.

#### **25.5.2.4.1 ADMA Concept and Descriptor Format**

For ADMA1, including the following descriptors:

- Valid/Invalid descriptor.
- Nop descriptor.
- Set data length descriptor.
- Set data address descriptor.
- Link descriptor.
- Interrupt flag and End flag in descriptor.

For ADMA2, including the following descriptors:

- Valid/Invalid descriptor.
- Nop descriptor.
- Rsv descriptor.
- Set data length & address descriptor.
- Link descriptor.
- Interrupt flag and End flag in descriptor.

ADMA will start read/write operation after it reaches the Tran state, using the data length and data address analyzed from most recent descriptor(s).

For ADMA1, the valid data length descriptor is the last Set type descriptor before Tran type descriptor. Every Tran type will trigger a transfer, and the transfer data length is extracted from the most recent Set type descriptor. If there is no Set type descriptor after the previous Trans descriptor, the data length will be the value for previous transfer, or 0 if no Set descriptor is ever met.

## Functional Description

For ADMA2, Tran type descriptor contains both data length and transfer data address, so only a Tran type descriptor can start a data transfer

See the figure below for the format of the descriptor table for ADMA1.

Address/ Page Field		Address/ Page Field		Attribute Field					
31	12	11	6	5	4	3	2	1	0
Address or Data Length		000000		Act 2	Act 1	0	Int	End	Valid

Act 2	Act1	Symbol	Comment	31- 28	27- 12
0	0	Nop	No Operation	Don't Care	
0	1	Set	Set Data Length	0000	Data Length
1	0	Tran	Transfer Data	Data Address	
1	1	Link	Link Descriptor	Descriptor Address	

Valid	Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is processed.

**Figure 25-8. Format of the ADMA1 Descriptor Table**

**Figure 25-9. Concept and Access Method of ADMA1 Descriptor Table**

The figure below explains the ADMA2 format. ADMA2 deals with the lower 32-bit first, and then the higher 32-bit. If the 'Valid' flag of descriptor is 0, it will ignore the high 32-bit. Address field shall be set on word aligned(lower 2-bit is always set to 0). Data length is in byte unit.

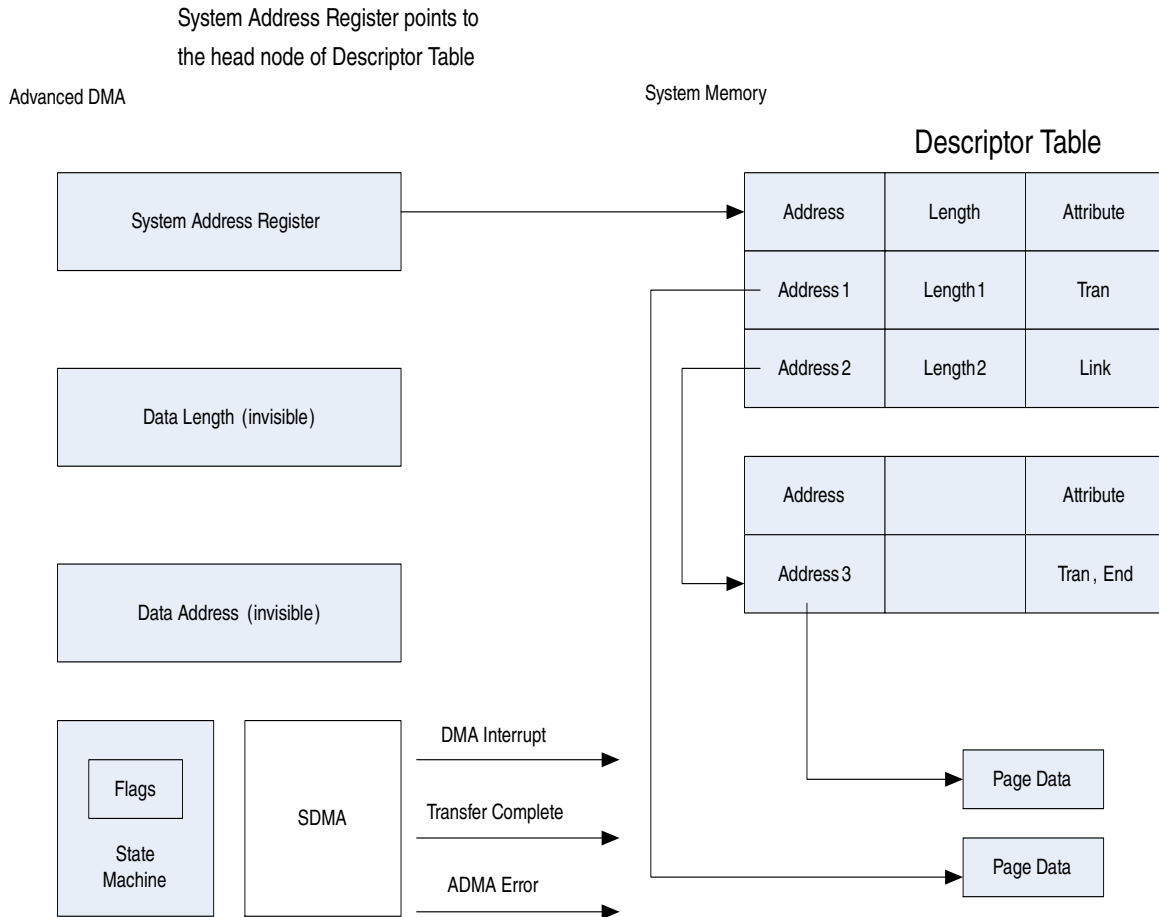

## Functional Description

Address Field		Length		Reserved		Attribute Field					
63	32	31	16	15	06	05	04	03	02	01	00
32-bit Address		16-bit length		0000000000		Act 2	Act 1	0	Int	End	Valid

Act 2	Act1	Symbol	Comment	Operation
0	0	Nop	No Operation	Don't Care
0	1	Rsv	Reserved	Same as Nop. Read this line and go to next one
1	0	Tran	Transfer Data	Transfer data with address and length set in this descriptor line
1	1	Link	Link Descriptor	Link to another descriptor

Valid	Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is processed.

**Figure 25-10. Format of the ADMA2 Descriptor Table**

**Figure 25-11. Concept and Access Method of ADMA2 Descriptor Table**

### 25.5.2.4.2 ADMA Interrupt

If the interrupt flag descriptor is set, ADMA will generate an interrupt according to various types of descriptors:

For ADMA1:

- Set type of descriptor: interrupt is generated when data length is set.
- Tran type descriptor: interrupt is generated when this transfer is complete.
- Link type of descriptor: interrupt is generated when new descriptor address is set.
- Nop type of descriptor: interrupt is generated just after this descriptor is fetched.

For ADMA2:

- Tran type of descriptor: interrupt is generated when this transfer is complete.
- Link type of descriptor: interrupt is generated when new descriptor address is set.
- Nop/Rsv type of descriptor: interrupt is generated just after this descriptor is fetched.

### 25.5.2.4.3 ADMA Error

The ADMA will stop whenever any error is encountered. These errors include:

- Fetching descriptor error
- AHB response error
- Data length mismatch error

An ADMA descriptor error will be generated when it fails to detect a 'Valid' flag in the descriptor. If an ADMA descriptor error occurs, the interrupt is not generated even if the 'Interrupt' flag of this descriptor is set.

When BLKCNTEN bit is set, data length set in buffer must be equal to the whole data length set in descriptor nodes, otherwise data length mismatch error will be generated.

When BLKCNTEN bit is not set, then whole data length set in descriptor should be a multiple of block lengths; otherwise, when data set in the descriptor nodes are not performed at block boundaries, then data mismatch errors will occur.

## 25.5.3 Register Bank with IP Bus Interface

Register accesses via the IP Bus interface are actually on the Register Bank.

See the figure below for the block diagram.

**Figure 25-12. Register Bank Diagram**

Only 32-bit access is allowed, and no partial read / write is supported, thus all accesses are word aligned.

### 25.5.3.1 SD Protocol Unit

The SD protocol unit deals with all SD protocol affairs.

The SD Protocol Unit performs the following functions:

- Acts as the bridge between the internal buffer and the SD bus
- Sends the command data as well as its argument serially
- Stores the serial response bit stream into corresponding registers
- Detects the bus state on the CMD/DAT lines
- Monitors the interrupt from the SDIO card
- Asserts the read wait signal
- Gates off the SD clock when buffer is announcing danger status
- Detects the write protect state

The SD Protocol Unit consists of four sub modules:

1. SD control misc.

2. Command control.
3. Data control.
4. Clock control

### **25.5.3.2 SD control misc**

In the SD control misc unit, the card detect(include the CD\_B and DATA3 used as Card Detection), write protection and card interrupt are implemented.

This module monitors the signal level on all 8 data lines, the command lines, and directly routes the level values into the Register Bank. The driver can use this for debug purposes.

The module also detects the WP (Write Protect) line. If WP is active, writes to the register bank will be ignored.

This module also drives the LCTL output signal when the LCTL bit is set by the driver.

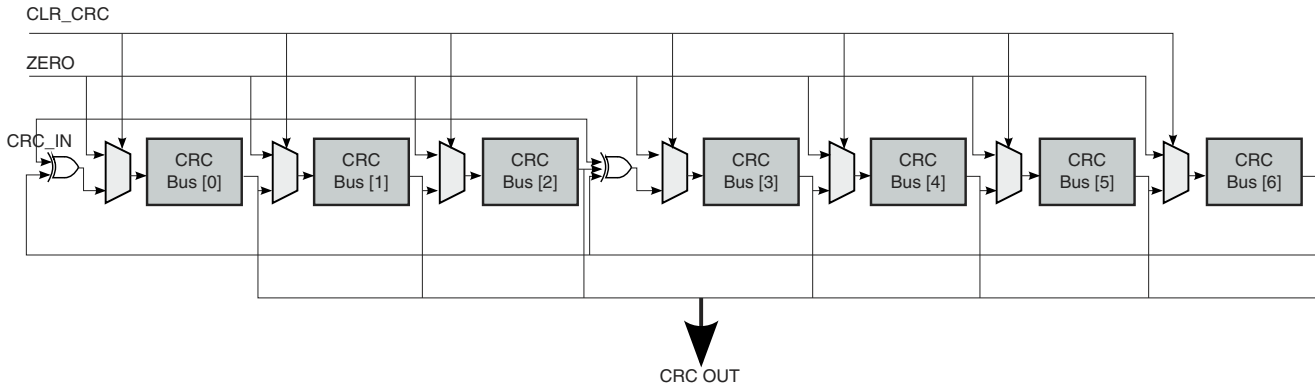

### **25.5.3.3 SD Clock control**

If the internal data buffer is near full(for read) or near empty(for write), the SD clock must be gated off to avoid buffer over/under-run, this module will assert the gate of the output SD clock to shut the clock off. After the buffer has space(for read) or has data(for write), the clock gate of this module will open and the SD clock will be active again.

### **25.5.3.4 Command control**

The Command Control module deals with the transactions on the CMD line.

See the figure below for an illustration of the structure for the Command CRC Shift Register.

**Figure 25-13. Command CRC Shift Register**

The CRC polynomials for the CMD are as follows:

Generator polynomial:  $G(x) = x^7 + x^3 + 1$   
 $M(x) = (\text{first bit}) * x^n + (\text{second bit}) * x^{n-1} + \dots + (\text{last bit}) * x^0$   
 $\text{CRC}[6:0] = \text{Remainder} [(M(x) * x^7) / G(x)]$

### 25.5.3.5 Data control

The Data Agent deals with the transactions on the eight data lines. Moreover, this module also detects the busy state on the DATA0 line, and generates the Read Wait state by the request from the Transceiver.

The CRC polynomials for the DATA are as follows:

Generator polynomial:  $G(x) = x^{16} + x^{12} + x^5 + 1$   
 $M(x) = (\text{first bit}) * x^n + (\text{second bit}) * x^{n-1} + \dots + (\text{last bit}) * x^0$   
 $\text{CRC}[15:0] = \text{Remainder} [(M(x) * x^{16}) / G(x)]$

## 25.5.4 Clock & Reset Manager

This module controls all the reset signals within the uSDHC.

There are four kinds of reset signals within uSDHC:

1. Hardware reset.
2. Software reset for all logic.
3. Software reset for the data logic.
4. Software reset for the command logic.

All these signals are fed into this module and stable signals are generated inside the module to reset all other modules. The module also gates off all the inside signals.

## 25.5.5 Clock Generator

The Clock Generator generates the card CLK by peripheral source clock in two stages.

Refer to the figure below for the structure of the divider. The term "Base" represents the frequency of peripheral source clock.

**Figure 25-14. Two Stages of the Clock Divider**

The first stage outputs an intermediate clock (DIV), which can be Base, Base/2, Base/3, ..., or Base/16.

The second stage is a prescaler, and outputs the actual internal working clock (card\_clk). This clock is the driving clock for all sub modules of the SD Protocol Unit, and the sync FIFOs (see [Figure 25-3](#)) to synchronize with the data rate from the internal data buffer. The frequency of the clock output from this stage, can be DIV, DIV/2, DIV/4, ..., or DIV/256. Thus the highest frequency of the card\_clk is Base, and the next highest is Base/2, while the lowest frequency is Base/4096. If the duty cycle of Base clock is 50%, the duty cycle of card\_clk is also 50%, even when the compound divisor is an odd value.

Please note, in SDR mode and DDR mode, the CLK are different.

- In SDR mode, CLK is equal to the internal working clock(card\_clk).
- In DDR mode, CLK is equal to the card\_clk/2.

## 25.5.6 SDIO Card Interrupt

Information on Interrupts in 1-bit Mode, Interrupts in 4-bit Mode, and Card Interrupt Handling are detailed in the sections below.

### 25.5.6.1 Interrupts in 1-bit Mode

In this case the DATA1 pin is dedicated to providing the interrupt function. An interrupt is asserted by pulling the DATA1 low from the SDIO card, until the interrupt service is finished to clear the interrupt.

### 25.5.6.2 Interrupt in 4-bit Mode

Since the interrupt and data line 1 share Pin 8 in 4-bit mode, an interrupt will only be sent by the card and recognized by the host during a specific time. This is known as the Interrupt Period. The uSDHC will only sample the level on Pin 8 during the Interrupt Period. At all other times, the host will ignore the level on Pin 8, and treat it as the data signal. The definition of the Interrupt Period is different for operations with single block and multiple block data transfers.

In the case of normal single data block transmissions, the Interrupt Period becomes active two clock cycles after the completion of a data packet. This Interrupt Period lasts until after the card receives the end bit of the next command that has a data block transfer associated with it.

For multiple block data transfers in 4-bit mode, there is only a limited period of time that the Interrupt Period can be active due to the limited period of data line availability between the multiple blocks of data. This requires a more strict definition of the Interrupt Period. For this case, the Interrupt Period is limited to two clock cycles. This begins two clocks after the end bit of the previous data block. During this 2-clock cycle interrupt period, if an interrupt is pending, the DATA1 line will be held low for one clock cycle with the last clock cycle pulling DATA1 high. On completion of the Interrupt Period, the card releases the DATA1 line into the high Z state. The uSDHC samples the DATA1 during the Interrupt Period when the IABG bit in the Protocol Control register is set.

Refer to SDIO Card Specification v1.10f for further information about the SDIO card interrupt.

### 25.5.6.3 Card Interrupt Handling

When the CINTIEN bit in the Interrupt Signal Enable Register is set to 0, the uSDHC clears the interrupt request to the Host System. The Host Driver should clear this bit before servicing the SDIO Interrupt and should set this bit again after all interrupt requests from the card are cleared to prevent inadvertent interrupts.

The SDIO Card Interrupt Status can be cleared by writing 1 to this bit. But as the interrupt source from the SDIO card does not clear, this bit is set again. In order to clear this bit, it is required to reset the interrupt source from the external card followed by a writing 1 to this bit. In 1-bit mode, the uSDHC will detect the SDIO Interrupt with or without the SD clock (to support wakeup). In 4-bit mode, the interrupt signal is sampled during the Interrupt Period, so there are some sample delays between the interrupt signal from the SDIO card and the interrupt to the Host System Interrupt Controller. When the

## Functional Description

SDIO status has been set, and the Host Driver needs to service this interrupt, so the SDIO bit in the Interrupt Control Register of SDIO card will be cleared. This is required to clear the SDIO interrupt status latched in the uSDHC and to stop driving the interrupt signal to the System Interrupt Controller. The Host Driver must issue a CMD52 to clear the card interrupt. After completion of the card interrupt service, the SDIO Interrupt Status Enable bit is set to 1, and the uSDHC starts sampling the interrupt signal again.

See the figure below for an illustration of the SDIO card interrupt scheme and for the sequences of software and hardware events that take place during a card interrupt handling procedure.

**Figure 25-15. Card Interrupt Scheme and Card Interrupt Detection and Handling Procedure**

## 25.5.7 Card Insertion and Removal Detection

The uSDHC uses either the DATA3 pin or the CD\_B pin to detect card insertion or removal. When there is no card on the MMC/SD bus, the DATA3 will be pulled to a low voltage level by default.

When any card is inserted to or removed from the socket, the uSDHC detects the logic value changes on the DATA3 pin and generates an interrupt. When the DATA3 pin is not used for card detection (for example, it is implemented in GPIO), the CD\_B pin must be connected for card detection. Whether DATA3 is configured for card detection or not, the CD\_B pin is always a reference for card detection. Whether the DATA3 pin or the CD\_B pin is used to detect card insertion, the uSDHC will send an interrupt (if enabled) to inform the Host system that a card is inserted.

## 25.5.8 Power Management and Wake Up Events

When there is no operation between the uSDHC and the card through the SD bus, the user can completely disable the ipg\_clk and ipg\_perclk in the chip level clock control module to save power. When the user needs to use the uSDHC to communicate with the card, it can enable the clock and start the operation.

In some circumstances, when the clocks to the uSDHC are disabled, for instance, when the system is in low power mode, there are some events for which the user needs to enable the clock and handle the event. These events are called wakeup interrupts. The uSDHC can generate these interrupt even when there are no clocks enabled. The three interrupts which can be used as wake up events are:

1. Card Removal Interrupt
2. Card Insertion Interrupt
3. Interrupt from SDIO card

The uSDHC offers a power management feature. By clearing the clock enabled bits in the System Control Register, the clocks are gated in the low position to the uSDHC. For maximum power saving, the user can disable all the clocks to the uSDHC when there is no operation in progress.

These three wake up events (or wakeup interrupts) can also be used to wake up the system from low-power modes.

### NOTE

To make the interrupt a wakeup event, when all the clocks to the uSDHC are disabled or when the whole system is in low power mode, the corresponding wakeup enabled bit needs to be

set. Refer to [Protocol Control \(PROT\\_CTRL\)](#) for more information on the uSDHC Protocol Control register.

### 25.5.8.1 Setting Wake Up Events

For the uSDHC to respond to a wakeup event, the software must set the respective wakeup enable bit before the CPU enters sleep mode.

Before the software disables the host clock, it should ensure that all of the following conditions have been met:

- No Read or Write Transfer is active
- Data and Command lines are not active
- No interrupts are pending
- Internal data buffer is empty

## 25.5.9 MMC fast boot

The Embedded MultiMediaCard (eMMC4.3) specification adds a fast boot feature which requires hardware support. There are two types of fast boot mode, boot operation, and alternative boot operation in the eMMC4.3 specification. Each type also has with-acknowledge and without-acknowledge modes.

In boot operation mode, the master (MultiMediaCard host) can read boot data from the slave (MMC device) by keeping CMD line low after power-on, or sending CMD0 with argument + 0xFFFFFFFFFA (optional for slave), before issuing CMD1.

### NOTE

For the eMMC4.3 card setting, please see the eMMC4.3 specification.

### 25.5.9.1 Boot operation

### NOTE

For the purposes of this documentation, fast boot is called "normal fast boot mode".

If the CMD line is held LOW for 74 clock cycles and more after power-up before the first command is issued, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within 1 second after the CMD line goes LOW, the slave starts to send the first boot data to the master on the DATA line(s). The master must keep the CMD line LOW to read all of the boot data.

If boot acknowledge is enabled, the slave has to send acknowledge pattern '010' to the master within 50ms after the CMD line goes LOW. If boot acknowledge is disabled, the slave will not send out acknowledge pattern '010'.

The master can terminate boot mode with the CMD line HIGH.

Boot operation will be terminated when all contents of the enabled boot data are sent to the master. After boot operation is executed, the slave shall be ready for CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.

**Figure 25-16. MultiMediaCard state diagram (normal boot mode)**

### 25.5.9.2 Alternative boot operation

This boot function is optional for the device. If bit 0 in the extended CSD byte[228] is set to '1', the device supports the alternative boot operation.

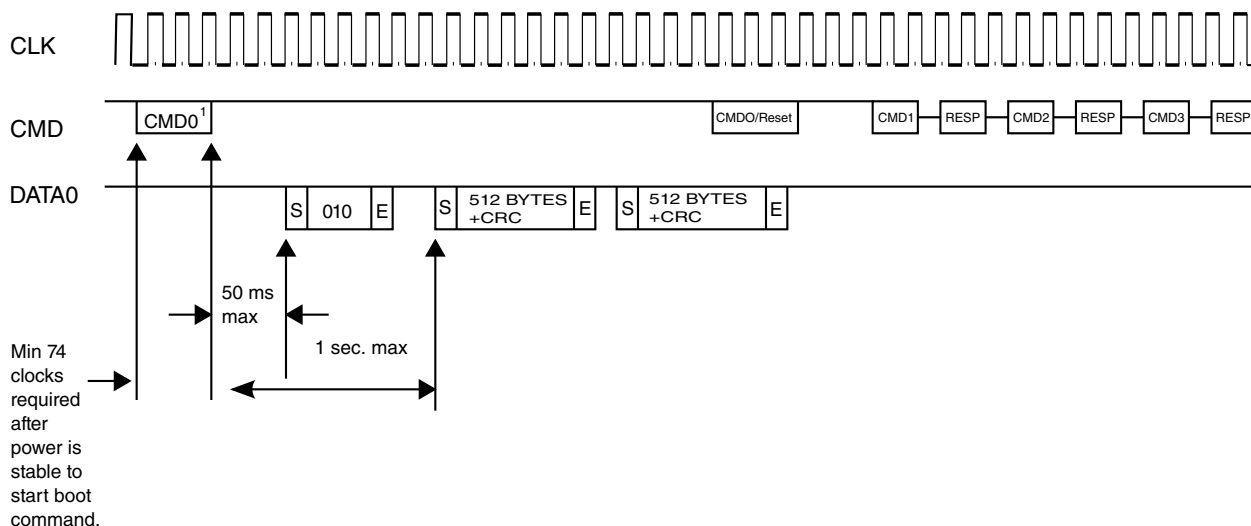

After power-up, if the host issues CMD0 with the argument of 0xFFFFFFFFFA after 74 clock cycles, before CMD1 is issued or the CMD line goes low, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within 1 second after CMD0 with the argument of 0xFFFFFFFFFA is issued, the slave starts to send the first boot data to the master on the DATA line(s).

If boot acknowledge is enabled, the slave has to send the acknowledge pattern '010' to the master within 50ms after the CMD0 with the argument of 0xFFFFFFFFFA is received. If boot acknowledge is disabled, the slave will not send out acknowledge pattern '010'.

The master can terminate boot mode by issuing CMD0 (Reset).

Boot operation will be terminated when all contents of the enabled boot data are sent to the master. After boot operation is executed, the slave shall be ready for CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.

NOTE 1. CMD0 with argument 0xFFFFFFFF

Figure 25-17. MultiMediaCard state diagram (alternative boot mode)

## 25.6 Initialization/Application of uSDHC

All communication between the system and cards are controlled by the host. The host sends commands of two types: broadcast and addressed (point-to-point).

Broadcast commands are intended for all cards, such as GO\_IDLE\_STATE, SEND\_OP\_COND, ALL\_SEND\_CID. In Broadcast mode, all cards are in the open-drain mode to avoid bus contention. Refer to [Commands for MMC/SD/SDIO](#) for the commands of bc and bcr categories.

After the Broadcast command CMD3 is issued, the cards enter standby mode. Addressed type commands are used from this point. In this mode, the CMD/DATA I/O pads will turn to push-pull mode, to have the driving capability for maximum frequency operation. Refer to [Commands for MMC/SD/SDIO](#) for the commands of ac and adtc categories.

## 25.6.1 Command Send & Response Receive Basic Operation

Assuming the data type WORD is an unsigned 32-bit integer, the below flow is a guideline for sending a command to the card(s):

```
send_command(cmd_index, cmd_arg, other requirements)
{
WORD wCmd; // 32-bit integer to make up the data to write into Transfer Type register, it is
recommended to implement in a bit-field manner
wCmd = (<cmd_index> & 0x3f) >> 24; // set the first 8 bits as '00'+<cmd_index>
set CMDTYP, DPSEL, CICCEN, CCCEN, RSTTYP, DTDSEL accorind to the command_index;
if (internal DMA is used) wCmd |= 0x1;
if (multi-block transfer) {
    set MSBSEL bit;
    if (finite block number) {
        set BCEN bit;
        if (auto12 command is to use) set AC12EN bit;
    }
}
write_reg(CMDARG, <cmd_arg>); // configure the command argument
write_reg(XFERTYP, wCmd); // set Transfer Type register as wCmd value to issue the command
}
wait_for_response(cmd_index)
{
while (CC bit in IRQ Status register is not set); // wait until Command Complete bit is set
read IRQ Status register and check if any error bits about Command are set
if (any error bits are set) report error;
write 1 to clear CC bit and all Command Error bits;
}
```

For the sake of simplicity, the function `wait_for_response` is implemented here by means of polling. For an effective and formal way, the response is usually checked after the Command Complete Interrupt is received. When doing this, make sure the corresponding interrupt status bits are enabled.

For some scenarios, the response time-out is expected. For instance, after all cards respond to CMD3 and go to the Standby State, no response to the Host when CMD2 is sent. The Host Driver will deal with "fake" errors like this with caution.

## 25.6.2 Card Identification Mode

When a card is inserted to the socket or the card was reset by the host, the host needs to validate the operation voltage range, identify the cards, request the cards to publish the Relative Card Address (RCA) or to set the RCA for the MMC cards.

### 25.6.2.1 Card Detect

See the figure below for a flow diagram showing the detection of MMC, SD and SDIO cards using the uSDHC.

**Figure 25-18. Flow Diagram for Card Detection**

Here is the card detect sequence:

- Set the CINSIEN bit to enable card detection interrupt
- When an interrupt from the uSDHC is received, check the CINS bit in the Interrupt Status register to see if it was caused by card insertion
- Clear the CINSIEN bit to disable the card detection interrupt and ignore all card insertion interrupts afterwards

### 25.6.2.2 Reset

The host consists of three types of resets:

- Hardware reset (Card and Host) which is driven by POR (Power On Reset)

- Software reset (Host Only) is initiated by the write operation on the RSTD, RSTC, or RSTA bits of the System Control register to reset the data part, command part, or all parts of the Host Controller, respectively
- Card reset (Card Only). The command, "Go\_Idle\_State" (CMD0), is the software reset command for all types of MMC cards, SD Memory cards. This command sets each card into the Idle State regardless of the current card state. For an SD I/O Card, CMD52 is used to write an I/O reset in the CCCR. The cards are initialized with a default relative card address (RCA=0x0000) and with a default driver stage register setting (lowest speed, highest driving current capability).

After the card is reset, the host needs to validate the voltage range of the card. See the figure below for the software flow to reset both the uSDHC and the card.

**Figure 25-19. Flow Chart for Reset of the uSDHC and SD I/O Card**

```

software_reset()
{
set_bit(SYSCTRL, RSTA); // software reset the Host
set_DTOCV and SDCLKFS bit fields to get the CLK of frequency around 400kHz
configure IO pad to set the power voltage of external card to around 3.0V
poll bits CIHB and CDIHB bits of PRSSTAT to wait both bits are cleared
set_bit(SYSCTRL, INTIA); // send 80 clock ticks for card to power up
send_command(CMD_GO_IDLE_STATE, <other parameters>); // reset the card with CMD0
or send_command(CMD_IO_RW_DIRECT, <other parameters>);
}
  
```

### 25.6.2.3 Voltage Validation

All cards should be able to establish communication with the host using any operation voltage in the maximum allowed voltage range specified in the card specification. However, the supported minimum and maximum values for V<sub>dd</sub> are defined in the Operation Conditions Register (OCR) and may not cover the whole range.

Cards that store the CID and CSD data in the preload memory are only able to communicate this information under data transfer Vdd conditions. This means if the host and card have non-common Vdd ranges, the card will not be able to complete the identification cycle, nor will it be able to send CSD data.

Therefore, a special command Send\_Op\_Cont (CMD1 for MMC), SD\_Send\_Op\_Cont (ACMD41 for SD Memory) and IO\_Send\_Op\_Cont (CMD5 for SD I/O) is used. The voltage validation procedure is designed to provide a mechanism to identify and reject cards which do not match the Vdd range(s) desired by the host. This is accomplished by the host sending the desired Vdd voltage window as the operand of this command. Cards that can't perform the data transfer in the specified range must discard themselves from further bus operations and go into the Inactive State. By omitting the voltage range in the command, the host can query each card and determine the common voltage range before sending out-of-range cards into the Inactive State. This query should be used if the host is able to select a common voltage range or if a notification shall be sent to the system when a non-usable card in the stack is detected.

The following steps show how to perform voltage validation when a card is inserted:

```

voltage_validation(voltage_range_argument)
{
label the card as UNKNOWN;
send_command(IO_SEND_OP_COND, 0x0, <other parameters are omitted>); // CMD5, check SDIO
operation voltage, command argument is zero
if (RESP_TIMEOUT != wait_for_response(IO_SEND_OP_COND)) { // SDIO command is accepted
    if (0 < number of IO functions) {
        label the card as SDIO;
        IORDY = 0;
        while (!(IORDY in IO OCR response)) { // set voltage range for each IO
function
            send_command(IO_SEND_OP_COND, <voltage range>, <other
parameter>);
            wait_for_response(IO_SEND_OP_COND);
        } // end of while ...
    } // end of if (0 < ...
    if (memory part is present inside SDIO card) Label the card as SDCCombo; // this is
an
SD-Combo card
} // end of if (RESP_TIMEOUT ...
if (the card is labelled as SDIO card) return; // card type is identified and voltage range
is
set, so exit the function;
send_command(APP_CMD, 0x0, <other parameters are omitted>); // CMD55, Application specific
CMD
prefix
if (no error calling wait_for_response(APP_CMD, <...>) { // CMD55 is accepted
    send_command(SD_APP_OP_COND, <voltage range>, <...>); // ACMD41, to set voltage
range
for memory part or SD card
    wait_for_response(SD_APP_OP_COND); // voltage range is set
    if (Card type is UNKNOWN) label the card as SD;
    return; //
} // end of if (no error ...
else if (errors other than time-out occur) { // command/response pair is corrupted
    deal with it by program specific manner;
} // of else if (response time-out
else { // CMD55 is refuse, it must be MMC card if (card is already labelled as SDCCombo)
{ //
change label

```

```

        re-label the card as SDIO;
        ignore the error or report it;
        return; // card is identified as SDIO card
    } // of if (card is ...
    send_command(SEND_OP_COND, <voltage range>, <...>);
    if (RESP_TIMEOUT == wait_for_response(SEND_OP_COND)) { // CMD1 is not accepted,
either
        label the card as UNKNOWN;
        return;
    } // of if (RESP_TIMEOUT ...
} // of else
}

```

### 25.6.2.4 Card Registry

Card registry for the MMC and SD/SDIO/SD Combo cards are different. For the SD Card, the Identification process starts at a clock rate lower than 400 kHz and the power voltage higher than 2.7 V (as defined by the Card spec). At this time, the CMD line output drives are push-pull drivers instead of open-drain. After the bus is activated, the host will request the card to send their valid operation conditions.

The response to ACMD41 is the operation condition register of the card. The same command shall be send to all of the new cards in the system. Incompatible cards are put into the Inactive State. The host then issues the command, All\_Send\_CID (CMD2), to each card to get its unique card identification (CID) number. Cards that are currently unidentified (in the Ready State), send their CID number as the response. After the CID is sent by the card, the card goes into the Identification State.

The host then issues Send\_Relative\_Addr (CMD3), requesting the card to publish a new relative card address (RCA) that is shorter than the CID. This RCA will be used to address the card for future data transfer operations. Once the RCA is received, the card changes its state to the Standby State. At this point, if the host wants the card to have an alternative RCA number, it may ask the card to publish a new number by sending another Send\_Relative\_Addr command to the card. The last published RCA is the actual RCA of the card.

The host repeats the identification process with CMD2 and CMD3 for each card in the system until the last CMD2 gets no response from any of the cards in system.

For MMC operation, the host starts the card identification process in open-drain mode with the identification clock rate lower than 400 kHz and the power voltage higher than 2.7 V. The open drain driver stages on the CMD line allow parallel card operation during card identification. After the bus is activated the host will request the cards to send their valid operation conditions (CMD1). The response to CMD1 is the "wired OR" operation on the condition restrictions of all cards in the system. Incompatible cards are sent into the Inactive State. The host then issues the broadcast command All\_Send\_CID (CMD2), asking all cards for their unique card identification (CID) number. All unidentified cards

(the cards in Ready State) simultaneously start sending their CID numbers serially, while bit-wise monitoring their outgoing bit stream. Those cards, whose outgoing CID bits do not match the corresponding bits on the command line in any one of the bit periods, stop sending their CID immediately and must wait for the next identification cycle. Since the CID is unique for each card, only one card can be successfully send its full CID to the host. This card then goes into the Identification State. Thereafter, the host issues Set\_Relative\_Addr (CMD3) to assign to the card a relative card address (RCA). Once the RCA is received the card state changes to the Stand-by State, and the card does not react in further identification cycles, and its output driver switches from open-drain to push-pull. The host repeats the process, mainly CMD2 and CMD3, until the host receives a time-out condition to recognize the completion of the identification process.

For operation as MMC cards:

```
card_registry()
{
do { // decide RCA for each card until response time-out
    if(card is labelled as SDCombo or SDIO) { // for SDIO card like device
        send_command(SET_RELATIVE_ADDR, 0x00, <...>); // ask SDIO card to
publish its
RCA
        retrieve RCA from response;
    } // end if (card is labelled as SDCombo ...
else if (card is labelled as SD) { // for SD card
    send_command(ALL_SEND_CID, <...>);
    if (RESP_TIMEOUT == wait_for_response(ALL_SEND_CID)) break;
    send_command(SET_RELATIVE_ADDR, <...>);
    retrieve RCA from response;
} // else if (card is labelled as SD ...
else if (card is labelled as MMC) {
    send_command(ALL_SEND_CID, <...>);
    rca = 0x1; // arbitrarily set RCA, 1 here for example
    send_command(SET_RELATIVE_ADDR, 0x1 << 16, <...>); // send RCA at upper
16
bits
        } // end of else if (card is labelled as MMC ...
} while (response is not time-out);
}
```

## 25.6.3 Card Access

Information about Block Write, Block Read, Suspend Resume, ADMA Usage, Transfer Error, and Card Interrupt are detailed in the sections below.

### 25.6.3.1 Block Write

Information on Normal Write, DDR Write, and Write with Pause are detailed in the sections below.

### 25.6.3.1.1 Normal Write

During a block write (CMD24 - 27, CMD60, CMD61), one or more blocks of data are transferred from the host to the card with a CRC appended to the end of each block by the host. If the CRC fails, the card shall indicate the failure on the DATA line. The transferred data will be discarded and not written, and all further transmitted blocks (in multiple block write mode) will be ignored.

If the host uses partial blocks whose accumulated length is not block aligned and block misalignment is not allowed (CSD parameter WRITE\_BLK\_MISALIGN is not set), the card detects the block misalignment error and aborts the programming before the beginning of the first misaligned block. The card sets the ADDRESS\_ERROR error bit in the status register, and while ignoring all further data transfer, waits in the Receive-data-State for a stop command. The write operation is also aborted if the host tries to write over a write protected area.

For MMC and SD cards, programming of the CID and CSD registers does not require a previous block length setting. The transferred data is also CRC protected. If a part of the CSD or CID register is stored in ROM, then this unchangeable part must match the corresponding part of the receive buffer. If this match fails, then the card will report an error and not change any register contents.

For all types of cards, some may require long and unpredictable periods of time to write a block of data. After receiving a block of data and completing the CRC check, the card will begin writing and hold the DATA line low if its write buffer is full and unable to accept new data from a new WRITE\_BLOCK command. The host may poll the status of the card with a SEND\_STATUS command (CMD13) or other means for SDIO cards at any time, and the card will respond with its status. The responded status indicates whether the card can accept new data or whether the write process is still in progress. The host may deselect the card by issuing a CMD7 (to select a different card) to place the card into the Standby State and release the DATA line without interrupting the write operation. When re-selecting the card, it will reactivate the busy indication by pulling DATA to low if the programming is still in progress and the write buffer is unavailable.

The software flow to write to a card incorporates the internal DMA and the write operation is a multi-block write with the Auto CMD12 enabled. For the other methods (CPU polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to write to a card is described below:

1. Check the card status, wait until the card is ready for data.
2. Set the card block length/size:

- For SD/MMC cards, use SET\_BLOCKLEN (CMD16)
  - For SDIO cards or the I/O portion of SDCombo cards, use IO\_RW\_DIRECT (CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the uSDHC block length register to be the same as the block length set for the card in Step 2.
  4. Set the uSDHC number block register (NOB), nob is 5 (for instance).
  5. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
  6. Wait for the Transfer Complete interrupt.
  7. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

### 25.6.3.1.2 DDR Write

uSDHC supports dual data rate mode.

The software flow to write to a card in ddr mode is described as below:

1. Check the card status, wait until the card is ready for data.
2. For eMMC4.4 card, block length only can be set to 512byte.
3. Set the uSDHC number block register (NOB), nob is 5 (for instance).
4. Set eMMC4.4 card to high speed mode, use SWITCH(CMD6).
5. Set eMMC4.4 card bus with (4-bit /8-bit ddr mode), use SWITCH(CMD6).
6. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The DDR\_EN bit should be set. The AC12EN bit should also be set.
7. Wait for the Transfer Complete interrupt.
8. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

### 25.6.3.1.3 Write with Pause

The write operation can be paused during the transfer. Instead of stopping the CLK at any time to pause all the operations, which is also inaccessible to the Host Driver, the Driver can set the Stop At Block Gap Request(SABGREQ) bit in the Protocol Control register to pause the transfer between the data blocks. As there is no time-out condition in a write operation during the data blocks, a write to all types of cards can be paused in this way, and if the DATA0 line is not required to de-assert to release the busy state, no suspend command is needed.

Like in the flow described in [Normal Write](#), the write with pause is shown with the same kind of write operation:

1. Check the card status, wait until card is ready for data.
2. Set the card block length/size:
  - For SD/MMC, use SET\_BLOCKLEN (CMD16)
  - For SDIO cards or the I/O portion of SDCombo cards, use IO\_RW\_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the uSDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the uSDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Set the SABGREQ bit.
7. Wait for the Transfer Complete interrupt.
8. Clear the SABGREQ bit.
9. Check the status bit to see if a write CRC error occurred.
10. Set the CREQ bit to continue the write operation.
11. Wait for the Transfer Complete interrupt.
12. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

The number of blocks left during the data transfer is accessible by reading the contents of the BLKCNT field in the Block Attribute register. As the data transfer and the setting of the SABGREQ bit are concurrent, and the delay of register read and the register setting, the actual number of blocks left may not be exactly the value read earlier. The Driver shall read the value of BLKCNT after the transfer is paused and the Transfer Complete interrupt is received.

It is also possible the last block has begun when the Stop At Block Gap Request is sent to the buffer. In this case, the next block gap is actually the end of the transfer. These types of requests are ignored and the Driver should treat this as a non-pause transfer and deal with it as a common write operation.

When the write operation is paused, the data transfer inside the Host System is not stopped, and the transfer is active until the data buffer is full. Because of this (if not needed), it is recommended to avoid using the Suspend Command for the SDIO card. This is because when such a command is sent, the uSDHC thinks the System will switch to another function on the SDIO card, and flush the data buffer. The uSDHC takes the Resume Command as a normal command with data transfer, and it is left for the Driver to set all the relevant registers before the transfer is resumed. If there is only one block to

send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set as well as the AC12EN bit. However, the uSDHC will automatically send a CMD12 to mark the end of the multi-block transfer.

### 25.6.3.2 Block Read

Information about Normal Read, DDR Read, Read with Pause, and DLL (Delay Line) in Read Path are detailed in the sections below.

#### 25.6.3.2.1 Normal Read

For block reads, the basic unit of data transfer is a block whose maximum size is stored in areas defined by the corresponding card specification. A CRC is appended to the end of each block, ensuring data transfer integrity. The CMD17, CMD18, CMD53, CMD60, CMD61, and so on, can initiate a block read. After completing the transfer, the card returns to the Transfer State. For multi blocks read, data blocks will be continuously transferred until a stop command is issued.

The software flow to read from a card incorporates the internal DMA and the read operation is a multi-block read with the Auto CMD12 enabled. For the other methods (CPU polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to read from a card is described below:

1. Check the card status, wait until card is ready for data.
2. Set the card block length/size:
  - For SD/MMC, use SET\_BLOCKLEN (CMD16)
  - For SDIO cards or the I/O portion of SDCombo cards, use IO\_RW\_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the uSDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the uSDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer read ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a read CRC error occurred, or some another error, occurred during the auto12 command sending and response receiving.

### 25.6.3.2.2 DDR Read

uSDHC supports dual data rate mode.

The software flow to write to a card in ddr mode is described below:

1. Check the card status, wait until the card is ready for data.
2. For eMMC4.4 card, block length only can be set to 512byte.
3. Set the uSDHC number block register (NOB), nob is 5 (for instance).
4. Set eMMC4.4 card to high speed mode, use SWITCH(CMD6).
5. Set eMMC4.4 card bus with (4-bit /8-bit ddr mode), use SWITCH(CMD6).
6. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The DDR\_EN bit should be set. The AC12EN bit should also be set.
7. Wait for the Transfer Complete interrupt.
8. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

### 25.6.3.2.3 Read with Pause

The read operation is not generally able to pause. Only the SDIO card (and SDCombo card working under I/O mode) supporting the Read Wait feature can pause during the read operation. If the SDIO card supports Read Wait (SRW bit in CCCR register is 1), the Driver can set the SABGREQ bit in the Protocol Control register to pause the transfer between the data blocks.

Before setting the SABGREQ bit, make sure the RWCTL bit in the Protocol Control register is set, otherwise the uSDHC will not assert the Read Wait signal during the block gap and data corruption occurs. It is recommended to set the RWCTL bit once the Read Wait capability of the SDIO card is recognized.

Like in the flow described in [Normal Read](#), the read with pause is shown with the same kind of read operation:

1. Check the SRW bit in the CCR register on the SDIO card to confirm the card supports Read Wait.
2. Set the RWCTL bit.
3. Check the card status and wait until the card is ready for data.
4. Set the card block length/size:
  - For SD/MMC, use SET\_BLOCKLEN (CMD16)
  - For SDIO cards or the I/O portion of SDCombo cards, use IO\_RW\_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)

5. Set the uSDHC block length register to be the same as the block length set for the card in Step 2.
6. Set the uSDHC number block register (NOB), nob is 5 (for instance).
7. Disable the buffer read ready interrupt, configure the DMA setting and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set
8. Set the SABGREQ bit.
9. Wait for the Transfer Complete interrupt.
10. Clear the SABGREQ bit.
11. Check the status bit to see if read CRC error occurred.
12. Set the CREQ bit to continue the read operation.
13. Wait for the Transfer Complete interrupt.
14. Check the status bit to see if a read CRC error occurred, or some another error, occurred during the auto12 command sending and response receiving.

Like the write operation, it is possible to meet the ending block of the transfer when paused. In this case, the uSDHC will ignore the Stop At Block Gap Request and treat it as a command read operation.

Unlike the write operation, there is no remaining data inside the buffer when the transfer is paused. All data received before the pause will be transferred to the Host System. No matter if the Suspend Command is sent or not, the internal data buffer is not flushed.

If the Suspend Command is sent and the transfer is later resumed by means of a Resume Command, the uSDHC takes the command as a normal one accompanied with data transfer. It is left for the Driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set, as well as the AC12EN bit. However, the uSDHC will automatically send the CMD12 to mark the end of multi-block transfer.

#### **25.6.3.2.4 DLL (Delay Line) in Read Path**

The DLL(Delay Line) is newly added to assist in sampling read data. The DLL provides the ability to programmatically select a quantized delay (in fractions of the clock period) regardless of on-chip variations such as process, voltage and temperature (PVT).

The reasons why the DLL is needed for uSDHC are 1.) the path of read data traveling from card to host varies. 2.) in SD/MMC DDR mode the minimum input setup and hold time are both at 2.5 ns. The data sampling window is so small that the delay of loopback clock needs to be accurate and consistent regardless of PVT. The DLL takes the divided card\_clk as the reference clock and loopback clock as the input clock. It then generates a delayed version of the input clock according to the programmed target delay.

The DLL can be disabled or bypassed, and it can also be manually set for a fixed delay in override mode. The override value set is the number of delay cells. In override mode, there is no need to set the `DLL_enable`. Another DLL mode is target value mode. In this mode, the DLL will automatically adjust the number of delay cells according to target value set by user and PVT changes. Be aware that target value is in units of 1/32 of the clock reference period. If the `card_clk` is 100Mhz, then the reference clock period is 10ns, setting target value of 16 means  $5\text{ns} = (16/32) * 10\text{ns}$ . Software can disable automatic update by setting `dll_gate_update` bit.

Since the user may change the frequency of the `card_clk` from time to time by changing `SDCLKFS[7:0]/DVS[3:0]`, the software must adjust the delay value to ensure it works correctly when the reference clock (`card_clk`) is changed. The following is the correct flow, which should be ignored if `DLL_CTRL_ENABLE` is not set.

Step 1: Set `DLL_CTRL_RESET` bit

Step 2: Configure the `SDCLKFS[7:0]` and `DVS[3:0]`

Step 3: Wait until `SDSTB` is asserted

Step 4: clear `DLL_CTRL_RESET` bit

Step 5: Wait until both `DLL_STS_SLV_LOCK` and `DLL_STS_REF_LOCK` are asserted

Step 6: set `DLL_CTRL_SLV_FORCE_UPD`

Step 7: clear `DLL_CTRL_SLV_FORCE_UPD`

#### **NOTE**

Software should make sure the `DLL_CTRL_SLV_FORCE_UPD` is lasted for at least one `card_clk`. So software may need to add some delay between Step6 and Step7.

Figure 25-20. DLL(Delay Line) in Read Path

### 25.6.3.3 Suspend Resume

The uSDHC supports the Suspend Resume operations of SDIO cards, although slightly differently than the suggested implementation of Suspend in the SDIO card specification.

#### 25.6.3.3.1 Suspend

After setting the SABGREQ bit, the Host Driver may send a Suspend command to switch to another function of the SDIO card. The uSDHC does not monitor the content of the response, so it doesn't know if the Suspend command succeeded or not. Accordingly, it doesn't de-assert Read Wait for read pause. To solve this problem, the Driver shall not mark the Suspend command as a "Suspend", (i.e. setting the CMDTYP bits to 01). Instead, the Driver shall send this command as if it were a normal command, and only

when the command succeeds, and the BS bit is set in the response, can the Driver send another command marked as "Suspend" to inform the uSDHC that the current transfer is suspended. As shown in the following sequence for Suspend operation:

1. Set the SABREQ bit to pause the current data transfer at block gap.
2. After the BGE bit is set, send the Suspend command to suspend the active function. The CMDTYP bit field must be 2'b00.
3. Check the BS bit of the CCCR in the response. If it is 1, repeat this step until the BS bit is cleared or abandon the suspend operation according to the Driver strategy.
4. Send another normal I/O command to the suspended function. The CMDTYP of this command must be 2'b01, so the uSDHC can detect this special setting and be informed that the paused operation has successfully suspended. If the paused transfer is a read operation, the uSDHC stops driving DATA2 and goes to the idle state.
5. Save the context registers in the system memory for later use, including the DMA System Address Register (for internal DMA operation), and the Block Attribute Register.
6. Begin operation for another function on the SDIO card.

### 25.6.3.3.2 Resume

To resume the data transfer, a Resume command shall be issued:

1. To resume the suspended function, restore the context register with the saved value in step #5 of the Suspend operation above.
2. Send the Resume command. In the Transfer Type register, all bit fields are set to the value as if this were another ordinary data transfer, instead of a transfer resume (except the CMDTYP is set to 2'b10).
3. If the Resume command has responded, the data transfer will be resumed.

### 25.6.3.4 ADMA Usage

To use the ADMA in a data transfer, the Host Driver must prepare the correct descriptor chain prior to sending the read/write command.

The steps to prepare the correct descriptor chain are:

1. Create a descriptor to set the data length that the current descriptor group is about to transfer. The data length should be even numbers of the block size.
2. Create another descriptor to transfer the data from the address setting in this descriptor. The data address must be at a page boundary (4kB address aligned).
3. If necessary, create a Link descriptor containing the address of the next descriptor. The descriptor group is created in steps 1 ~ 3.

4. Repeat steps 1 ~ 3 until all descriptors are created.
5. In the last descriptor, set the End flag to 1 and make sure the total length of all descriptors match the product of the block size and block number configured in the Block Attribute Register.
6. Set the ADMA System Address Register to the address of the first descriptor and set the DMAS field in the Protocol Control Register to 01 to select the ADMA.
7. Issue a write or read command with the DMAEN bit set to 1 in the Transfer Type Register.

Steps 1 ~ 5 are independent of step 6, so step 6 can finish before steps 1 ~ 5. Regarding the descriptor configuration, it is recommended not to use the Link descriptor as it requires extra system memory access.

### 25.6.3.5 Transfer Error

Information about CRC, Internal DMA, Transfer ADMA, and Auto CMD12 Errors are detailed in the sections below.

#### 25.6.3.5.1 CRC Error

It is possible at the end of a block transfer, that a write CRC status error or read CRC error occurs. For this type of error the latest block received shall be discarded. This is because the integrity of the data block is not guaranteed. It is recommended to discard the following data blocks and re-transfer the block from the corrupted one.

For a multi-block transfer, the Host Driver shall issue a CMD12 to abort the current process and start the transfer by a new data command. In this scenario, even when the AC12EN and BCEND bits are set, the uSDHC does not automatically send a CMD12 because the last block is not transferred. On the other hand, if it is within the last block that the CRC error occurs, an Auto CMD12 will be sent by the uSDHC. In this case, the Driver shall re-send or re-obtain the last block with a single block transfer.

#### 25.6.3.5.2 Internal DMA Error

During the data transfer with internal Simple DMA, if the DMA engine encounters some error on the AHB bus, the DMA operation is aborted and DMA Error interrupt is sent to the Host System. When acknowledged by such an interrupt, the Driver shall calculate the start address of data block in which the error occurs.

The start address can be calculated by either:

1. Reading the DMA System Address register. The error occurs during the previous burst. Taking the block size, the previous burst length and the start address of the

next burst transfer into account, it is straight forward to obtain the start address of the corrupted block.

2. Reading the BLKCNT field of the Block Attribute register. By the number of blocks left, the total number to transfer, the start address of transfer, and the size of each block, the start address of corrupted block can be determined. When the BCEN bit is not set, the contents of the Block Attribute register does not change, so this method does not work.

When a DMA error occurs, it is recommended to abort the current transfer by means of a CMD12 (for multi block transfer), apply a reset for data, and re-start the transfer from the corrupted block to recover from the error.

### 25.6.3.5.3 Transfer ADMA Error

There are 3 kinds of possible ADMA errors. The AHB transfer, invalid descriptor, and data-length mismatch errors. Whenever these errors occur, the DMA transfer stops and the corresponding error status bit is set.

For acknowledging the status, the Host Driver should recover the error as shown below and re-transfer from the place of interruption.

1. AHB transfer error: Such errors may occur during data transfer or descriptor fetch. For either scenario, it is recommended to retrieve the transfer context, reset for the data part and re-transfer the block that was corrupted, or the next block if no block is corrupted.
2. Invalid descriptor error: For such errors, it is recommended to retrieve the transfer context, reset for the data part and re-create the descriptor chain from the invalid descriptor and issue a new transfer. As the data to transfer now may be less than the previous setting, the data length configured in the new descriptor chain should match the new value.
3. Data-length mismatch error: It is similar to recover from this error. The Host Driver polls relating registers to retrieve the transfer context, apply a reset for the data part, configure a new descriptor chain, and make another transfer if there is data left. Like the previous scenario of the invalid descriptor error, the data length must match the new transfer.

### 25.6.3.5.4 Auto CMD12 Error

After the last block of the multi block transfer is sent or received, and the AC12EN bit is set when the data transfer is initiated by the data command, the uSDHC automatically sends a CMD12 to the card to stop the transfer.

When errors with this command occur, it is recommended to the Driver to deal with the situations in the following manner:

1. Auto CMD12 response time-out. It is not certain whether the command is accepted by the card or not. The Driver should clear the Auto CMD12 error status bits and re-send the CMD12 until it is accepted by the card.
2. Auto CMD12 response CRC error. Since card responds to the CMD12, the card will abort the transfer. The Driver may ignore the error and clear the error status bit.
3. Auto CMD12 conflict error or not sent. The command is not sent, so the Driver shall send a CMD12 manually.

### 25.6.3.6 Card Interrupt

The external cards can inform the Host Controller by means of some special signals. For the SDIO card, it can be the low level on the DATA1 line during some special period. The uSDHC only monitors the DATA1 line and supports the SDIO interrupt.

When the SDIO interrupt is captured by the uSDHC, and the Host System is informed by the uSDHC asserting the uSDHC interrupt line, the interrupt service from the Host Driver is called.

As the interrupt source is controlled by the external card, the interrupt from the SDIO card must be serviced before the CINT bit is cleared by written. Refer to [Card Interrupt Handling](#) for the card interrupt handling flow.

### 25.6.4 Switch Function

A switch command shall be issued by the Host Driver to enable new features added to the SD/MMC spec. SD/MMC cards can transfer data at bus widths other than 1-bit. Different speed mode are also defined. To enable these features, a switch command shall be issued by the Host Driver.

For SDIO cards, the high speed mode/DDR50/SDR50/SDR104 are enabled by writing the EHS bit in the CCCR register after the SHS bit is confirmed. For SD cards, the high speed mode/DDR50/SDR50/SDR104 are queried and enabled by a CMD6 (with the mnemonic symbol as SWITCH\_FUNC). For MMC cards, the high speed mode/HS200 are queried by a CMD8 and enabled by a CMD6 (with the mnemonic symbol as SWITCH).

The SDR4-bit, SDR8-bit, DDR4-bit and DDR8-bit width of the MMC is also enabled by the SWITCH command, but with a different argument.

These new functions can also be disabled by a software reset. For SDIO cards it can be done by setting the RES bit in the CCCR register. For other cards, it can be accomplished by issuing a CMD0. This method of restoring to the normal mode is not recommended because a complete identification process is needed before the card is ready for data transfer.

For the sake of simplicity, the following pseudocode examples do not show current capability check, which is recommended in the function switch process.

### 25.6.4.1 Query, Enable and Disable SDIO High Speed Mode

```
enable_sdio_high_speed_mode(void)
{
send CMD52 to query bit SHS at address 0x13;
if (SHS bit is '0') report the SDIO card does not support high speed mode and return;
send CMD52 to set bit EHS at address 0x13 and read after write to confirm EHS bit is set;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of around 50MHz;
(data transactions like normal peers)
}
disable_sdio_high_speed_mode(void)
{
send CMD52 to clear bit EHS at address 0x13 and read after write to confirm EHS bit is
cleared;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

### 25.6.4.2 Query, Enable and Disable SD High Speed Mode/SDR50/SDR104/DDR50

```
enable_sd_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0xFFFFF0 and read 64 bytes of data accompanying the R1 response;
(high speed mode,x=1; SDR50,x=2; SDR104,x=3; DDR50,x=4;)
wait data transfer done bit is set;
check if the bit x of received 512 bits is set;
if (bit 401 is '0') report the SD card does not support high speed mode and return;
if (bit 402 is '0') report the SD card does not support SDR50 mode and return;
if (bit 403 is '0') report the SD card does not support SDR104 mode and return;
if (bit 404 is '0') report the SD card does not support DDR50 mode and return;
send CMD6, with argument 0x80FFFFF0 and read 64 bytes of data accompanying the R1 response;
(high speed mode,x=1; SDR50,x=2; SDR104 x=3; DDR50 x=4;)
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of around 50MHz for high speed mode, 100Mhz for SDR50, 200Mhz for SDR104, 50Mhz for
DDR50;
(data transactions like normal peers)
}
disable_sd_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0x80FFFFF0 and read 64 bytes of data accompanying the R1 response;
check if the bit field 379~376 is 0xF;
```

## Initialization/Application of uSDHC

```
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

### 25.6.4.3 Query, Enable and Disable MMC High Speed Mode

```
enable_mmc_high_speed_mode(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support high speed mode and
return;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
extract the value of CARD_TYPE field to check the 'high speed mode' in this MMC is 26MHz or
52MHz;
send CMD6 with argument 0x1B90100;
send CMD13 to wait card ready (busy line released);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 1;
if (HS_TIMING is not 1) report MMC switching to high speed mode failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of around 26MHz or 52MHz according to the CARD_TYPE;
(data transactions like normal peers)
}
disable_mmc_high_speed_mode(void)
{
send CMD6 with argument 0x2B90100;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 0;
if (HS_TIMING is not 0) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 20MHz;
(data transactions like normal peers)
}
```

### 25.6.4.4 Set MMC Bus Width

```
change_mmc_bus_width(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support multiple bit width and
return;
send CMD6 with argument 0x3B70x00; (8-bit(dual data rate), x=6; 4-bit(dual data rate), x=5;8-
bit, x=2; 4-bit, x=1; 1-bit, x=0)
send CMD13 to wait card ready (busy line released);
(data transactions like normal peers)
}
```

## 25.6.5 ADMA Operation

Code for ADMA1 Operation and ADMA2 Operation can be found here.

### 25.6.5.1 ADMA1 Operation

```

Set_adma1_descriptor
{
if (to start data transfer) {
// Make sure the address is 4KB align.
Set 'Set' type descriptor;
{
Set Act bits to 01;
Set [31:12] bits data length (byte unit);
}
Set 'Tran' type descriptor;
{
Set Act bits to 10;
Set [31:12] bits address (4KB align);
}
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to 11;
Set [31:12] bits the next descriptor address (4KB aligned);
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set End bit to 1;
}
if (to generate interrupt for this descriptor) {
Set Int bit to 1;
}
Set Valid bit to 1;
}

```

### 25.6.5.2 ADMA2 Operation

```

Set_adma2_descriptor
{
if (to start data transfer) {
// Make sure the address is a 32-bit boundary (lower 2-bit are always '00').
Set higher 32-bit of descriptor for this data transfer initial address;
Set [31:16] bits data length (byte unit);
Set Act bits to '10';
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to '11';
// Make sure the address is 32-bit boundary (lower 2-bit are always set to '00').
Set higher 32-bit of descriptor for the next descriptor address;
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set 'End' bit '1';
}
if (to generate interrupt for this descriptor) {
Set 'Int' bit '1';
}
Set the 'Valid' bit to '1';
}

```

## 25.6.6 Fast Boot Operation

### 25.6.6.1 Normal fast boot flow

1. Software must configure `init_active` bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software must configure the MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 0 (normal fast boot), and bit 4 to select the ack mode or not. If the data will be sent through DMA mode, the software should configure bit 7 to enable the automatic stop at block gap feature, and configure bit 3-bit 0 to select the ack timeout value according to the SD CLK frequency.
3. Software then needs to configure the Block Attributes Register to set the block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes.
4. Software must configure the Protocol control register to set DTW (data transfer width). If in DDR fast boot mode, DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software needs to configure the Command Argument Register to set argument if needed (no need in normal fast boot).
6. Software must configure the Transfer Type Register to start the boot process. In normal boot mode, `CMDINX`, `CMDTYP`, `RSPTYP`, `CICEN`, `CCEN`, `AC12EN`, `BCEN` and `DMAEN` are kept at the default value. `DPSEL` bit is set to 1, `DTDSEL` is set to 1, `MSBSEL` is set to 1.
7. `DMAEN` should be configured as 0 in polling mode. And if `BCEN` is configured as 1, it is recommended to configure the number of blocks in the Block Attributes Register to the maximum value. If in DDR fast boot mode, `DDR_EN` needs to be set to 1.
8. When the step 6 is configured, the boot process will begin. Software needs to poll the data buffer ready status to read the data from the buffer in time. If a boot timeout happens (ack times out or the first data read times out), an interrupt will be triggered, and software must configure MMC Boot Register to bit 6 to 0 to disable boot. This makes `CMD` high, then after at least 56 clocks, it is ready to begin a normal initialization process.
9. If there is no timeout, software needs to determine when the data read is finished and then configure MMC Boot Register bit 6 to 0 to disable boot. This will make `CMD` line high and command completed asserted. After at least 56 clocks, it is ready to begin normal initialization process.
10. Reset the host and then can begin the normal process.

### 25.6.6.2 Alternative fast boot flow

1. Software needs to configure `init_active` bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software needs to configure MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 1 (alternative boot), and bit 4 to select the ack mode or not. If data needs to be sent through DMA mode, then configure bit 7 to enable the automatic stop at block gap feature. Software should also configure bit 3-bit 0 to select the ack timeout value according to the SD clock frequency.
3. Software then needs to configure Block Attributes Register to set the block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes.
4. Software needs to configure the Protocol control register to set the DTW (data transfer width). If in ddr fast boot mode, DTW only can be configure to 4-bit/8-bit dataline mode.
5. Software needs to configure Command Argument Register to set argument to 0xFFFFFFFFFA.
6. Software needs to configure the Transfer Type Register to start the boot process by CMD0 with 0xFFFFFFFFFA argument . In alternative boot, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN are kept default value. DPSEL bit is set to 1, DTDSEL is set to 1, MSBSEL is set to 1. Note DMAEN should be configured as 0 in polling mode. And if BCEN is configured as 1 in polling mode, it is recommended to configure the block count in the Block Attributes Register to the maximum value. If in DDR fast boot mode, DDR\_EN needs to be set to 1.
7. When the step 6 is configured, the boot process will begin. Software needs to poll the data buffer ready status to read the data from the buffer in time. If there is a boot timeout (ack data timeout in 50ms or data timeout in 1s), the host will send out the interrupt and software needs to send CMD0 with reset and then configure the boot enable bit to 0 to stop this process..
8. If there is no time out, software needs to decide when to stop the boot process, and send out the CMD0 with reset and then after the command is completed, configure the MMC Boot Register bit 6 to stop the process. After 8 clocks from the command completion, the slave (card) is ready for the identification step.
9. Reset the host and then begin the normal process.

### 25.6.6.3 Fast boot application case (in DMA mode)

In the boot application case, because the image destination and the image size are contained in the beginning of the image, it is necessary to switch DMA parameters on the fly during MMC fast boot.

In fast boot, the host can use ADMA2 (Advanced DMA2) with two destinations.

The detail flow is described below:

1. Software needs to configure INIT\_ACTIVE bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software needs to configure the MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot); and bit 5 to 0 (normal fast boot) or 1 (alternative boot); and bit 4 to select the ack mode or not. In DMA mode, configure bit 7 to 1 to enable the automatic stop at block gap feature. Also configure bits[31-16] to set the (BLK\_CNT - VALUE1). Here VALUE1 is the value of the block count that needs to transfer the first time, so that that the host will stop at the block gap when the uSDHC controller gets VALUE1 blocks from the device. Also configure bits[3-0] to select the ack timeout value according to the SD clock frequency.
3. Software then needs to configure the Block Attributes Register to set block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes. In DMA mode, it is recommended to set the block count (BLK\_CNT) to the max value (16'hfff).
4. Software needs to configure Protocol Control Register to set DTW (data transfer width). If in DDR fast boot mode, the DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software enable ADMA2 by configuring Protocol Control Register bits [9-8].
6. Software need to set at least three pairs ADMA2 descriptor in boot memory (ie, in IRAM, at least 6 word). The first pair descriptor define the start address (ie, IRAM) and data length (ie, 512byte\*VALUE1) of first part boot code. Software also need to set the second pair descriptor, the second start address (any value that is writeable), data length is suggest to set 1~2word (record as VALUE2). Note: the second couple desc also transfer useful data even at lease 1 word. Because our ADMA2 can't support 0 data\_length data transfer descriptor.
7. Software needs to configure Command Argument Register to set argument to 0xFFFFFFFF in alternative fast boot, and don't need set in normal fast boot.
8. Software needs to configure Transfer Type Register to start the boot process . CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN are kept default value. DPSEL bit is set to 1, DTDSEL is set to 1, MSBSEL is set to 1. DMAEN is configured as 1 in DMA mode. And if BCEN is configured as 1, better to configure blk no in Block Attributes Register to the max value. And if in ddr fast boot mode, DDR\_EN need to be set to 1.
9. When the step 8 is configured, boot process will begin, the first VALUE1 block number data has transfer. Software need to polling TC bit (bit1 in Interrupt Status Register) to determine first transfer is end. Also software need to polling BGE bit (bit2 in Interrupt Status Register) to determine if first transfer stop at block gap.

10. When TC, BGE bit is 1, . SW can analyzes the first code of VALUE1 block, initializes the new memory device, if required, and sets the third pair of descriptors to define the start address and length of the remaining part of boot code(VALUE3 the remain boot code block). Remeber set the last descriptor with END.
11. Software needs to configure MMC Boot Register (offset 0xc4) again. Set bit 6 to 1(enable boot); and bit 5 to 0(normal fast boot), to 1(alternative boot); and bit 4 to select the ack mode or not. In DMA mode, configure bit 7 to 1 for enable automatically stop at block gap feature. Also configure bit31-bit16 to set the  $(BLK\_CNT - (VALUE1+1+VALUE3))$ , that host will stop at block gap when *the uSDHC controller gets (VALUE1+1+VALUE3) blocks from device totally include the blocks received in step 9*. And need to configure bit 3-bit0 to select the ack timeout value according to the sd clk frequence. Please note, Software doesn't need to configure the *BLK\_CNT* again, because it's counted down automatically by the uSDHC controller.
12. Software needs to clear TC and BGE bit. And software needs to clear SABGREQ(bit 16 in Protocol control register), and set CREQ(bit17 Protocol control register) to 1 to resume the data transfer. Host will transfer the VALUE2 and VALUE3 data to the destination that is set by descriptor.
13. Software need to polling BGE bit to determine if the fast boot is over.

Note:

1. When ADMA boot flow is started, for uSDHC, it is like a normal ADMA read operation. So setting ADMA2 descriptor as the normal ADMA2 transfer.
2. Need a few words length memory to keep descriptor.
3. For the 1~2 word data in second descriptor setting, it is the useful data, so software need to deal the data due to the application case.

## 25.7 Commands for MMC/SD/SDIO

A table containing the list of commands for the MMC/SD/SDIO cards can be found here.

Refer to the corresponding specifications for more details about the command information.

There are four kinds of commands defined to control the MultiMediaCard:

1. broadcast commands (bc), no response.
2. broadcast commands with response (bcr), response from all cards simultaneously.
3. addressed (point-to-point) commands (ac), no data transfer on the DATA.
4. addressed (point-to-point) data transfer commands (adtc).

Response: a response is a token which is sent from the card to the host as an answer to a previously received command. A response is transferred serially on the CMD line.

**Table 25-4. Commands for MMC/SD/SDIO Cards**

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD0	bc	[31:0] stuff bits	-	GO_IDLE_STATE	Resets all MMC and SD memory cards to idle state.
CMD1	bcr	[31:0] OCR without busy	R3	SEND_OP_COND	Asks all MMC and SD Memory cards in idle state to send their operation conditions register contents in the response on the CMD line.
CMD2	bcr	[31:0] stuff bits	R2	ALL_SEND_CID	Asks all cards to send their CID numbers on the CMD line.
CMD3 <sup>1</sup>	ac	[31:6] RCA [15:0] stuff bits	R1 R6 (SDIO)	SET/ SEND_RELATIVE_AD DR	Assigns relative address to the card.
CMD4	bc	[31:0] DSR [15:0] stuff bits	-	SET_DSR	Programs the DSR of all cards.
CMD5	bc	[31:0] OCR without busy	R4	IO_SEND_OP_COND	Asks all SDIO cards in idle state to send their operation conditions register contents in the response on the CMD line.
CMD6 <sup>2</sup>	adtc	[31] Mode 0: Check function 1: Switch function [30:8] Reserved for function groups 6 ~ 3 (All 0 or 0xFFFF) [7:4] Function group1 for command system [3:0] Function group2 for access mode	R1	SWITCH_FUNC	Checks switch ability (mode 0) and switch card function (mode 1). Refer to "SD Physical Specification V1.1" for more details.
CMD6 <sup>3</sup>	ac	[31:26] Set to 0 [25:24] Access [23:16] Index [15:8] Value [7:3] Set to 0 [2:0] Cmd Set	R1b	SWITCH	Switches the mode of operation of the selected card or modifies the EXT_CSD registers. Refer to "The MultiMediaCard System Specification Version 4.0 Final draft 2" for more details.
CMD7	ac	[31:6] RCA [15:0] stuff bits	R1b	SELECT/ DESELECT_CARD	Toggles a card between the stand-by and transfer states or between the programming and disconnect states. In both cases, the card is selected by its own relative address and gets deselected by any other address. Address 0 deselects all.

Table continues on the next page...

**Table 25-4. Commands for MMC/SD/SDIO Cards (continued)**

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD8	adtc	[31:0] stuff bits	R1	SEND_EXT_CSD	The card sends its EXT_CSD register as a block of data, with a block size of 512 bytes.
CMD9	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CSD	Addressed card sends its card-specific data (CSD) on the CMD line.
CMD10	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CID	Addressed card sends its card-identification (CID) on the CMD line.
CMD11	adtc	[31:0] data address	R1	READ_DAT_UNTIL_STOP	Reads data stream from the card, starting at the given address, until a STOP_TRANSMISSION follows.
CMD12	ac	[31:0] stuff bits	R1b	STOP_TRANSMISSION	Forces the card to stop transmission.
CMD13	ac	[31:6] RCA [15:0] stuff bits	R1	SEND_STATUS	Addressed card sends its status register.
CMD14	Reserved				
CMD15	ac	[31:6] RCA [15:0] stuff bits	-	GO_INACTIVE_STATE	Sets the card to inactive state in order to protect the card stack against communication breakdowns.
CMD16	ac	[31:0] block length	R1	SET_BLOCKLEN	Sets the block length (in bytes) for all following block commands (read and write). Default block length is specified in the CSD.
CMD17	adtc	[31:0] data address	R1	READ_SINGLE_BLOCK	Reads a block of the size selected by the SET_BLOCKLEN command.
CMD18	adtc	[31:0] data address	R1	READ_MULTIPLE_BLOCK	Continuously transfers data blocks from card to host until interrupted by a stop command.
CMD19	adtc	[31:0] reserved bits(all 0)	R1	SEND_TUNING_BLOCK	64 bytes tuning pattern is sent for SDR50 and SDR104.
CMD20	adtc	[31:0] data address	R1	WRITE_DAT_UNTIL_STOP	Writes data stream from the host, starting at the given address, until a STOP_TRANSMISSION follows.
CMD21	adtc	[31:0] stuff bits	R1	SEND_TUNING_BLOCK	128 clocks of tuning pattern (64 byte in 4 bit mode or 128 byte in 8 bit mode) is sent for HS200 optimal sampling point detection.
CMD22-23	Reserved				
CMD24	adtc	[31:0] data address	R1	WRITE_BLOCK	Writes a block of the size selected by the SET_BLOCKLEN command.
CMD25	adtc	[31:0] data address	R1	WRITE_MULTIPLE_BLOCK	Continuously writes blocks of data until a STOP_TRANSMISSION follows.

Table continues on the next page...

**Table 25-4. Commands for MMC/SD/SDIO Cards (continued)**

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD26	adtc	[31:0] stuff bits	R1	PROGRAM_CID	Programming of the card identification register. This command shall be issued only once per card. The card contains hardware to prevent this operation after the first programming. Normally this command is reserved for the manufacturer.
CMD27	adtc	[31:0] stuff bits	R1	PROGRAM_CSD	Programming of the programmable bits of the CSD.
CMD28	ac	[31:0] data address	R1b	SET_WRITE_PROT	If the card has write protection features, this command sets the write protection bit of the addressed group. The properties of write protection are coded in the card specific data (WP_GRP_SIZE).
CMD29	ac	[31:0] data address	R1b	CLR_WRITE_PROT	If the card provides write protection features, this command clears the write protection bit of the addressed group.
CMD30	adtc	[31:0] write protect data address	R1	SEND_WRITE_PROT	If the card provides write protection features, this command asks the card to send the status of the write protection bits.
CMD31	Reserved				
CMD32	ac	[31:0] data address	R1	TAG_SECTOR_START	Sets the address of the first sector of the erase group.
CMD33	ac	[31:0] data address	R1	TAG_SECTOR_END	Sets the address of the last sector in a continuous range within the selection of a single sector to be selected for erase.
CMD34	ac	[31:0] data address	R1	UNTAG_SECTOR	Removes one previously selected sector from the erase selection.
CMD35	ac	[31:0] data address	R1	TAG_ERASE_GROUP_START	Sets the address of the first erase group within a range to be selected for erase.
CMD36	ac	[31:0] data address	R1	TAG_ERASE_GROUP_END	Sets the address of the last erase group within a continuous range to be selected for erase.
CMD37	ac	[31:0] data address	R1	UNTAG_ERASE_GROUP	Removes one previously selected erase group from the erase selection.
CMD38	ac	[31:0] stuff bits	R1b	ERASE	Erase all previously selected sectors.
CMD39	ac	[31:0] RCA [15] register write flag	R4	FAST_IO	Used to write and read 8-bit (register) data fields. The command addresses a card, and a register, and provides the data for writing if

Table continues on the next page...

**Table 25-4. Commands for MMC/SD/SDIO Cards (continued)**

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
		[14:8] register address [7:0] register data			the write flag is set. The R4 response contains data read from the address register. This command accesses application dependent registers which are not defined in the MMC standard.
CMD40	bcr	[31:0] stuff bits	R5	GO_IRQ_STATE	Sets the system into interrupt mode.
CMD41	Reserved				
CDM42	adtc	[31:0] stuff bits	R1b	LOCK_UNLOCK	Used to set/reset the password or lock/unlock the card. The size of the data block is set by the SET_BLOCK_LEN command.
CMD43~51	Reserved				
CMD52	ac	[31:0] stuff bits	R5	IO_RW_DIRECT	Access a single register within the total 128k of register space in any I/O function.
CMD53	ac	[31:0] stuff bits	R5	IO_RW_EXTENDED	Accesses a multiple I/O register with a single command. Allows the reading or writing of a large number of I/O registers.
CMD54	Reserved				
CMD55	ac	[31:16] RCA [15:0] stuff bits	R1	APP_CMD	Indicates to the card that the next command is an application specific command rather than a standard command.
CMD56	adtc	[31:1] stuff bits [0]: RD/WR	R1b	GEN_CMD	Used either to transfer a data block to the card or to get a data block from the card for general purpose / application specific commands. The size of the data block is set by the SET_BLOCK_LEN command.
CMD57-59	Reserved				
CMD60	adtc	[31] WR [30:24] stuff bits [23:16] address [15:8] stuff bits [7:0] byte count	R1b	RW_MULTIPLE_REGISTER	These registers are used to control the behavior of the device and to retrieve status information regarding the operation of the device. All Status and Control registers are WORD (32-bit) in size and are WORD aligned. CMD60 shall be used to read and write these registers.
CMD61	adtc	[31] WR [30:16] stuff bits [15:0] data unit count	R1b	RW_MULTIPLE_BLOCK	The host issues a RW_MULTIPLE_BLOCK (CMD61) to begin the data transfer.
CMD62-63	Reserved				

Table continues on the next page...

**Table 25-4. Commands for MMC/SD/SDIO Cards (continued)**

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
ACMD6 <sup>4</sup>	ac	[31:2] stuff bits [1:0] bus width	R1	SET_BUS_WIDTH	Defines the data bus width ('00'=1bit or '10'=4bit bus) to be used for data transfer. The allowed data bus widths are given in SCR register.
ACMD13 <sup>4</sup>	adtc	[31:0] stuff bits	R1	SD_STATUS	Send the SD Memory Card status.
ACMD22 <sup>4</sup>	adtc	[31:0] stuff bits	R1	SEND_NUM_WR_SECTORS	Send the number of the written sectors (without errors). Responds with 32-bit plus the CRC data block.
ACMD23 <sup>4</sup>	ac	[31:23] stuff bits [22:0] Number of blocks	R1	SET_WR_BLK_ERASE_COUNT	Set the number of write blocks to be pre-erased before writing (to be used for fast Multiple Block WR command). "1"=default(one write block).
ACMD41 <sup>4</sup>	bcr	[31:0] OCR	R3	SD_APP_OP_COND	Asks the accessed card to send its operating condition register (OCR) contents in the response on the CMD line.
ACMD42 <sup>4</sup>	ac	[31:1] stuff bits [0] set_cd	R1	SET_CLR_CARD_DETECT	Connect(1)/Disconnect(0) the 50KOhm pull-up resistor on CD_B/DATA3 of the card.
ACMD51 <sup>4</sup>	adtc	[31:0] stuff bits	R1	SEND_SCR	Reads the SD Configuration Register (SCR).

1. CMD3 differs for MMC and SD cards. For MMC cards, it is referred to as SET\_RELATIVE\_ADDR, with a response type of R1. For SD cards, it is referred to as SEND\_RELATIVE\_ADDR, with a response type of R6 (with RCA inside).
2. CMD6 differs completely between high speed MMC cards and high speed SD cards. Command SWITCH\_FUNC is for high speed SD cards.
3. Command SWITCH is for high speed MMC cards. The Index field can contain any value from 0-255, but only values 0-191 are valid. If the Index value is in the 192-255 range the card does not perform any modification and the SWITCH\_ERROR status bit in the EXT\_CSD register is set. The Access Bits are shown in Table 2.
4. ACMDs shall be preceded with the APP\_CMD command. (Commands listed are used for SD only, other SD commands not listed are not supported on this module).

The Access Bits for the EXT\_CSD Access Modes are shown below.

**Table 25-5. EXT\_CSD Access Modes**

Bits	Access Name	Operation
00	Command Set	The command set is changed according to the Cmd Set field of the argument
01	Set Bits	The bits in the pointed byte are set, according to the 1 bits in the Value field.
10	Clear Bits	The bits in the pointed byte are cleared, according to the 1 bits in the Value field.
11	Write Byte	The Value field is written into the pointed byte.

## 25.8 Software Restrictions

### 25.8.1 Initialization Active

The driver cannot set INITA bit in System Control register when any of the command line or data lines is active, so the driver must ensure both CDIHB and CIHB bits are cleared.

### 25.8.2 Software Polling Procedure

For polling read or write, once the software begins a buffer read or write, it must access exactly the number of times as the values set in the Watermark Level Register; moreover, if the block size is not a multiple of the value in Watermark Level Register (read and write respectively), the software must access exactly the remaining number of words at the end of each block.

For example, for a read operation, if the RD\_WML is 4, indicating the watermark level is 16 bytes, block size is 40 bytes, and the block number is 2, then the access times for the burst sequence in the whole transfer process must be 4, 4, 2, 4, 4, 2.

### 25.8.3 Suspend Operation

In order to suspend the data transfer, the software must inform uSDHC that the suspend command is successfully accepted. To achieve this, after the Suspend command is accepted by the SDIO card, software must send another normal command marked as suspend command (CMDTYP bits set as '01') to inform uSDHC that the transfer is suspended.

If software needs to resume the suspended transfer, it should read the value in BLKCNT register to save the remaining number of blocks before sending the normal command marked as suspend, otherwise on sending such 'suspend' command, uSDHC will regard the current transfer is aborted and change BLKCNT register to its original value, instead of keeping the remained number of blocks.

## 25.8.4 Data Length Setting

For either ADMA (ADMA1 or ADMA2) transfer, the data in the data buffer must be word aligned, so the data length set in the descriptor must be a multiple of 4.

## 25.8.5 (A)DMA Address Setting

To configure ADMA1/ADMA2/DMA address register, when TC bit is set, the register will always update itself with the internal address value to support dynamic address synchronization, so the software must ensure that the TC bit is cleared prior to configuring ADMA1/ADMA2/DMA address register.

## 25.8.6 Data Port Access

Data Port does not support parallel access. For example, during an internal DMA access, it is not allowed to write any data to the Data Port by CPU; or during a CPU read operation, it is also prohibited to write any data to the Data Port, by either CPU or internal DMA. Otherwise the data would be corrupted inside the uSDHC buffer.

## 25.8.7 Change Clock Frequency

uSDHC does not automatically gate off the card clock when the Host Driver changes the clock frequency. To prevent possible glitch on the card clock, clear the FRC\_SDCLK\_ON bit when changing clock divisor value(SDCLKFS or DVS in System Control Register) or setting RSTA bit.

Also before changing the clock divisor value, Host Driver should make sure the SDSTB bit is high.

## 25.8.8 Multi-block Read

For pre-defined multi-block read operation, i.e., the number of blocks to read has been defined by previous CMD23 for MMC, or pre-defined number of blocks in CMD53 for SDIO/SDCombo, or whatever multi-block read without abort command at card side, an abort command, either automatic or manual CMD12/CMD52, is still required by uSDHC after the pre-defined number of blocks are done, to drive the internal state machine to idle mode.

In this case, the card may not respond to this extra abort command and uSDHC will get Response Timeout. It is recommended to manually send an abort command with RSPTYP[1:0] both bits cleared.

## 25.9 uSDHC Memory Map/Register Definition

### 25.9.1 uSDHC register descriptions

This section includes the module memory map and detailed descriptions of all registers.

See the table below for the register memory map for the uSDHC. All these registers only support 32-bit accesses.

#### NOTE

The uSDHC registers are 32-bit wide and only support 32-bit access.

#### 25.9.1.1 uSDHC Memory map

Base address: 402C\_0000h for uSDHC1, 402C\_4000h for uSDHC2.

Offset	Register	Width (In bits)	Access	Reset value
0h	<a href="#">DMA System Address (DS_ADDR)</a>	32	RW	0000_0000h

### 25.9.1.2 DMA System Address (DS\_ADDR)

#### 25.9.1.2.1 Offset

Register	Offset
DS_ADDR	0h

#### 25.9.1.2.2 Function

This register contains the physical system memory address used for DMA transfers.

### 25.9.1.2.3 Diagram

### 25.9.1.2.4 Fields

Field	Function
31-0 DS_ADDR	<p>DS_ADDR</p> <p><b>DMA System Address / Argument 2</b></p> <p>When ACMD23_ARGU2_EN is set to 0, SDMA uses this register as system address and supports only 32-bit addressing mode. Auto CMD23 cannot be used with SDMA. When ACMD23_ARGU2_EN is set to 1, SDMA uses ADMA System Address register (05Fh – 058h) instead of this register to support both 32-bit and 64-bit addressing. This register is used only for Argument2 and SDMA may use Auto CMD23.</p> <p><b>1. SDMA System Address</b></p> <p>Since the address must be word (4 bytes) aligned, the least 2 bits are reserved, always 0. When the uSDHC stops a DMA transfer, this register points out the system address of the next contiguous data position. It can be accessed only when no transaction is executing (i.e. after a transaction has stopped). Read operation during transfers may return an invalid value. The Host Driver shall initialize this register before starting a DMA transaction. After DMA has stopped, the system address of the next contiguous data position can be read from this register.</p> <p>This register is protected during a data transfer. When data lines are active, write to this register is ignored. The Host driver shall wait, until the DLA bit in the Present State register is cleared, before writing to this register.</p> <p>The uSDHC internal DMA does not support a virtual memory system. It only supports continuous physical memory access. And due to AHB burst limitations, if the burst must cross the 1 KB boundary, uSDHC will automatically change SEQ burst type to NSEQ.</p> <p>Since this register supports dynamic address reflecting, when TC bit is set, it automatically alters the value of internal address counter, so SW cannot change this register when TC bit is set. Such restriction is also listed in <a href="#">Software Restrictions</a>.</p> <p><b>2. Argument 2</b></p> <p>This register is used with the Auto CMD23 to set a 32-bit block count value to the argument of the CMD23 while executing Auto CMD23.</p> <p>If Auto CMD23 is used with ADMA, the full 32-bit block count value can be used. If Auto CMD23 is used without ADMA, the available block count value is limited by the Block Count register. 65535 blocks is the maximum value in this case.</p>

### 25.9.1.3 Block Attributes (BLK\_ATT)

#### 25.9.1.3.1 Offset

Register	Offset
BLK_ATT	4h

#### 25.9.1.3.2 Function

This register is used to configure the number of data blocks and the number of bytes in each block.

#### 25.9.1.3.3 Diagram

#### 25.9.1.3.4 Fields

Field	Function
31-16 BLKCNT	<p>Block Count</p> <p>Blocks Count For Current Transfer:</p> <p>This register is enabled when the Block Count Enable bit in the Transfer Mode register is set to 1 and is valid only for multiple block transfers. For single block transfer, this register will always read as 1. The Host Driver shall set this register to a value between 1 and the maximum block count. The uSDHC decrements the block count after each block transfer and stops when the count reaches zero. Setting the block count to 0 results in no data blocks being transferred.</p> <p>This register should be accessed only when no transaction is executing (i.e. after transactions are stopped). During data transfer, read operations on this register may return an invalid value and write operations are ignored.</p> <p>When saving transfer content as a result of a Suspend command, the number of blocks yet to be transferred can be determined by reading this register. The reading of this register should be applied after transfer is paused by stop at block gap operation and before sending the command marked as suspend.</p>

*Table continues on the next page...*

Field	Function
	<p>This is because when Suspend command is sent out, uSDHC will regard the current transfer is aborted and change BLKCNT register back to its original value instead of keeping the dynamical indicator of remained block count.</p> <p>When restoring transfer content prior to issuing a Resume command, the Host Driver shall restore the previously saved block count.</p> <p><b>NOTE:</b> Although the BLKCNT field is 0 after reset, the read of reset value is 0x1. This is because when MSBSEL bit is indicating a single block transfer, the read value of BLKCNT is always 1.</p> <p>0000000000000000b - Stop Count  0000000000000001b - 1 block  0000000000000010b - 2 blocks  1111111111111111b - 65535 blocks</p>
15-13 —	Reserved.
12-0 BLKSIZE	<p>Block Size</p> <p>Transfer Block Size:</p> <p>This register specifies the block size for block data transfers. Values ranging from 1 byte up to the maximum buffer size can be set. It can be accessed only when no transaction is executing (i.e. after a transaction has stopped). Read operations during transfers may return an invalid value, and write operations will be ignored.</p> <p>00000000000000b - No data transfer  00000000000001b - 1 Byte  00000000000010b - 2 Bytes  00000000000011b - 3 Bytes  0000000000100b - 4 Bytes  0000111111111b - 511 Bytes  0001000000000b - 512 Bytes  0100000000000b - 2048 Bytes  1000000000000b - 4096 Bytes</p>

## 25.9.1.4 Command Argument (CMD\_ARG)

### 25.9.1.4.1 Offset

Register	Offset
CMD_ARG	8h

### 25.9.1.4.2 Function

This register contains the SD / MMC Command Argument.

### 25.9.1.4.3 Diagram

### 25.9.1.4.4 Fields

Field	Function
31-0 CMDARG	Command Argument The SD / MMC Command Argument is specified as bits 39-8 of the Command Format in the SD or MMC Specification. This register is write protected when the Command Inhibit (CMD) bit in the Present State register is set.

## 25.9.1.5 Command Transfer Type (CMD\_XFR\_TYP)

### 25.9.1.5.1 Offset

Register	Offset
CMD_XFR_TYP	Ch

### 25.9.1.5.2 Function

This register is used to control the operation of data transfers. The Host Driver shall set this register before issuing a command followed by a data transfer, or before issuing a Resume command. To prevent data loss, the uSDHC prevents writing to the bits, that are involved in the data transfer of this register, when data transfer is active. These bits are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN and DMAEN.

The Host Driver shall check the Command Inhibit DAT bit (CDIHB) and the Command Inhibit CMD bit (CIHB) in the Present State register before writing to this register. When the CDIHB bit in the Present State register is set, any attempt to send a command with data by writing to this register is ignored; when the CIHB bit is set, any write to this register is ignored.

On sending commands with data transfer involved, it is mandatory that the block size is non-zero. Block count must also be non-zero, or indicated as single block transfer (bit 5 of this register is '0' when written), or block count is disabled (bit 1 of this register is '0' when written), otherwise uSDHC will ignore the sending of this command and do nothing. For write command, with all above restrictions, it is also mandatory that the write protect switch is not active (WPSPL bit of Present State Register is '1'), otherwise uSDHC will also ignore the command.

If the commands with data transfer does not receive the response in 64 clock cycles, i.e., response time-out, uSDHC will regard the external device does not accept the command and abort the data transfer. In this scenario, the driver should issue the command again to re-try the transfer. It is also possible that for some reason the card responds the command but uSDHC does not receive the response, and if it is internal DMA (either simple DMA or ADMA) read operation, the external system memory is over-written by the internal DMA with data sent back from the card.

The table below shows the summary of how register settings determine the type of data transfer.

**Table 25-6. Transfer Type Register Setting for Various Transfer Types**

Multi/Single Block Select	Block Count Enable	Block Count	Function
0	Don't Care	Don't Care	Single Transfer
1	0	Don't Care	Infinite Transfer
1	1	Positive Number	Multiple Transfer
1	1	Zero	No Data Transfer

The table below shows the relationship between the Command Index Check Enable and the Command CRC Check Enable, in regards to the Response Type bits as well as the name of the response type.

**Table 25-7. Relationship Between Parameters and the Name of the Response Type**

Response Type	Index Check Enable	CRC Check Enable	Name of Response Type
00	0	0	No Response
01	0	1	R2
10	0	0	R3,R4
10	1	1	R1,R5,R6
11	1	1	R1b,R5b

- In the SDIO specification, response type notation for R5b is not defined. R5 includes R5b in the SDIO specification. But R5b is defined in this specification to specify that the uSDHC will check the busy status after receiving a response. For example, usually CMD52 is used with R5, but the I/O abort command shall be used with R5b.
- The CRC field for R3 and R4 is expected to be all 1 bits. The CRC check shall be disabled for these response types.

### 25.9.1.5.3 Diagram

### 25.9.1.5.4 Fields

Field	Function
31-30	-
—	Reserved
29-24 CMDINX	Command Index These bits shall be set to the command number that is specified in bits 45-40 of the Command-Format in the SD Memory Card Physical Layer Specification and SDIO Card Specification.
23-22 CMDTYP	Command Type There are three types of special commands: Suspend, Resume and Abort. These bits shall be set to 00b for all other commands. <ul style="list-style-type: none"> <li>• Suspend Command: If the Suspend command succeeds, the uSDHC shall assume that the card bus has been released and that it is possible to issue the next command which uses the DATA line. Since the uSDHC does not monitor the content of command response, it does not know if the Suspend command succeeded or not. It is the Host Driver's responsibility to check the status of the Suspend command and send another command marked as Suspend to inform the uSDHC that a Suspend command was successfully issued. Refer to <a href="#">Suspend Resume</a> for more details. After the end bit of command is sent, the uSDHC de-asserts Read Wait for read transactions and stops checking busy for write transactions. In 4-bit mode, the interrupt cycle starts. If the Suspend command fails, the uSDHC will maintain its current state, and the Host Driver shall restart the transfer by setting the Continue Request bit in the Protocol Control register.</li> </ul>

Table continues on the next page...

Field	Function
	<ul style="list-style-type: none"> <li>Resume Command: The Host Driver re-starts the data transfer by restoring the registers saved before sending the Suspend Command and then sends the Resume Command. The uSDHC will check for a pending busy state before starting write transfers.</li> <li>Abort Command: If this command is set when executing a read transfer, the uSDHC will stop reads to the buffer. If this command is set when executing a write transfer, the uSDHC will stop driving the DATA line. After issuing the Abort command, the Host Driver should issue a software reset (Abort Transaction).</li> </ul> <p>00b - Normal Other commands  01b - Suspend CMD52 for writing Bus Suspend in CCCR  10b - Resume CMD52 for writing Function Select in CCCR  11b - Abort CMD12, CMD52 for writing I/O Abort in CCCR</p>
21 DPSEL	<p>Data Present Select</p> <p>This bit is set to 1 to indicate that data is present and shall be transferred using the DATA line. It is set to 0 for the following:</p> <ul style="list-style-type: none"> <li>Commands using only the CMD line (e.g. CMD52).</li> <li>Commands with no data transfer, but using the busy signal on DATA0 line (R1b or R5b e.g. CMD38)</li> </ul> <p><b>NOTE:</b> In resume command, this bit shall be set, and other bits in this register shall be set the same as when the transfer was initially launched. When the Write Protect switch is on, (i.e. the WPSPL bit is active as '0'), any command with a write operation will be ignored. That is to say, when this bit is set, while the DTDSEL bit is 0, writes to the register Transfer Type are ignored.</p> <p>0b - No Data Present  1b - Data Present</p>
20 CICEN	<p>Command Index Check Enable</p> <p>If this bit is set to 1, the uSDHC will check the Index field in the response to see if it has the same value as the command index. If it is not, it is reported as a Command Index Error. If this bit is set to 0, the Index field is not checked.</p> <p>0b - Disable  1b - Enable</p>
19 CCEN	<p>Command CRC Check Enable</p> <p>If this bit is set to 1, the uSDHC shall check the CRC field in the response. If an error is detected, it is reported as a Command CRC Error. If this bit is set to 0, the CRC field is not checked. The number of bits checked by the CRC field value changes according to the length of the response. (Refer to RSPTYP[1:0] and <a href="#">Command Transfer Type (CMD_XFR_TYP)</a> .)</p> <p>0b - Disable  1b - Enable</p>
18 —	- Reserved
17-16 RSPTYP	<p>Response Type Select</p> <p>00b - No Response  01b - Response Length 136  10b - Response Length 48  11b - Response Length 48, check Busy after response</p>

## 25.9.1.8 Command Response2 (CMD\_RSP2)

### 25.9.1.8.1 Offset

Register	Offset
CMD_RSP2	18h

### 25.9.1.8.2 Function

This register is used to store part 2 of the response bits from the card.

### 25.9.1.8.3 Diagram

### 25.9.1.8.4 Fields

Field	Function
31-0 CMDRSP2	Command Response 2 Refer to <a href="#">Command Response3 (CMD_RSP3)</a> for the mapping of command responses from the SD Bus to this register for each response type.

## 25.9.1.9 Command Response3 (CMD\_RSP3)

### 25.9.1.9.1 Offset

Register	Offset
CMD_RSP3	1Ch

### 25.9.1.9.2 Function

This register is used to store part 3 of the response bits from the card.

The table below describes the mapping of command responses from the SD Bus to Command Response registers for each response type. In the table, R[ ] refers to a bit range within the response data as transmitted on the SD Bus.

**Table 25-8. Response Bit Definition for Each Response Type**

Response Type	Meaning of Response	Response Field	Response Register
R1,R1b (normal response)	Card Status	R[39:8]	CMDRSP0

*Table continues on the next page...*

**Table 25-8. Response Bit Definition for Each Response Type (continued)**

Response Type	Meaning of Response	Response Field	Response Register
R1b (Auto CMD12 response)	Card Status for Auto CMD12	R[39:8]	CMDRSP3
R2 (CID, CSD register)	CID/CSD register [127:8]	R[127:8]	{CMDRSP3[23:0], CMDRSP2, CMDRSP1, CMDRSP0}
R3 (OCR register)	OCR register for memory	R[39:8]	CMDRSP0
R4 (OCR register)	OCR register for I/O etc.	R[39:8]	CMDRSP0
R5, R5b	SDIO response	R[39:8]	CMDRSP0
R6 (Publish RCA)	New Published RCA[31:16] and card status[15:0]	R[39:9]	CMDRSP0

This table shows that most responses with a length of 48 (R[47:0]) have 32-bits of the response data (R[39:8]) stored in the CMDRSP0 register. Responses of type R1b (Auto CMD12 responses) have response data bits (R[39:8]) stored in the CMDRSP3 register. Responses with length 136 (R[135:0]) have 120-bits of the response data (R[127:8]) stored in the CMDRSP0, 1, 2, and 3 registers.

To be able to read the response status efficiently, the uSDHC only stores part of the response data in the Command Response registers. This enables the Host Driver to efficiently read 32-bits of response data in one read cycle on a 32-bit bus system. Parts of the response, the Index field and the CRC, are checked by the uSDHC (as specified by the Command Index Check Enable and the Command CRC Check Enable bits in the Transfer Type register) and generate an error interrupt if any error is detected. The bit range for the CRC check depends on the response length. If the response length is 48, the uSDHC will check R[47:1], and if the response length is 136 the uSDHC will check R[119:1].

Since the uSDHC may have a multiple block data transfer executing concurrently with a CMD\_wo\_DAT command, the uSDHC stores the Auto CMD12 response in the CMDRSP3 register. The CMD\_wo\_DAT response is stored in CMDRSP0. This allows the uSDHC to avoid overwriting the Auto CMD12 response with the CMD\_wo\_DAT and vice versa. When the uSDHC modifies part of the Command Response registers, as shown in the table above, it preserves the unmodified bits.

### 25.9.1.9.3 Diagram

31-0 CMDRSP3	Command Response 3 Refer to <a href="#">Command Response3 (CMD_RSP3)</a> for the mapping of command responses from the SD Bus to this register for each response type.

## 25.9.1.10 Data Buffer Access Port (DATA\_BUFF\_ACC\_PORT)

### 25.9.1.10.1 Offset

Register	Offset
DATA_BUFF_ACC_PORT	20h

### 25.9.1.10.2 Function

This is a 32-bit data port register used to access the internal buffer.

### 25.9.1.10.3 Diagram

### 25.9.1.10.4 Fields

Field	Function
31-0 DATCONT	Data Content The Buffer Data Port register is for 32-bit data access by the ARM platform. When the internal DMA is enabled, any write to this register is ignored, and any read from this register will always yield 0s.

## 25.9.1.11 Present State (PRES\_STATE)

### 25.9.1.11.1 Offset

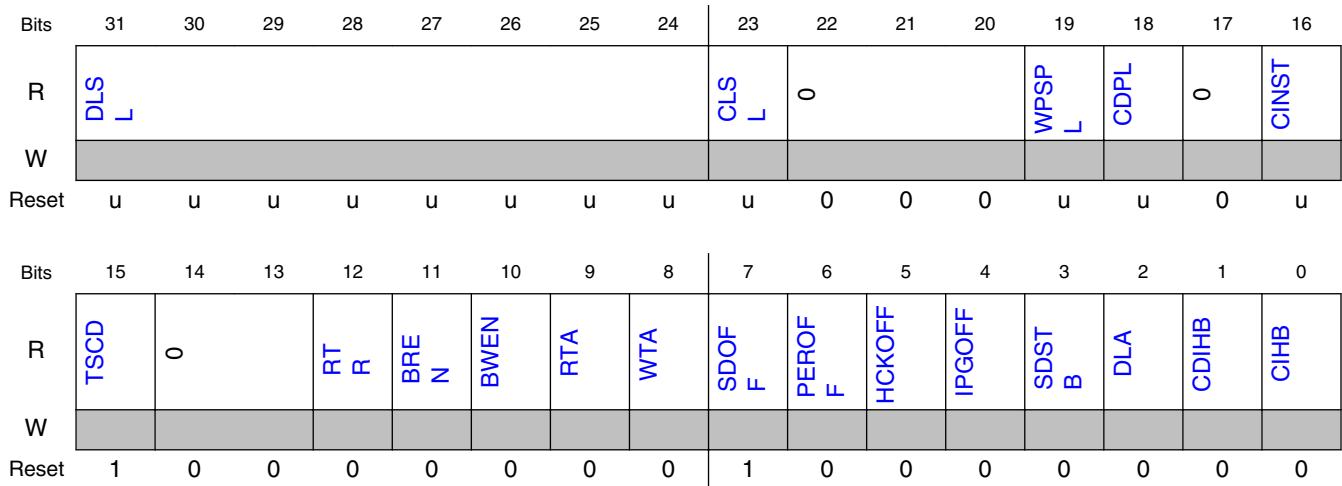

Register	Offset
PRES_STATE	24h

### 25.9.1.11.2 Function

The Host Driver can get status of the uSDHC from this 32-bit read only register.

- The Host Driver can issue CMD0, CMD12, CMD13 (for memory) and CMD52 (for SDIO) when the DATA lines are busy during a data transfer. These commands can be issued when Command Inhibit (CMD) is set to zero. Other commands shall be issued when Command Inhibit (DATA) is set to zero. Possible changes to the SD Physical Specification may add other commands to this list in the future.
- Note: the reset value of Present State Register depend on board connectivity.

### 25.9.1.11.3 Diagram

### 25.9.1.11.4 Fields

Field	Function
31-24 DLSL	<p>DATA[7:0] Line Signal Level</p> <p>This status is used to check the DATA line level to recover from errors, and for debugging. This is especially useful in detecting the busy signal level from DATA0. The reset value is affected by the external pull-up / pull-down resistors. By default, the read value of this bit field after reset is 8'b11110111, when DATA3 is pulled down and the other lines are pulled up.</p> <p>00000000b - Data 0 line signal level                      00000001b - Data 1 line signal level                      00000010b - Data 2 line signal level                      00000011b - Data 3 line signal level                      00000100b - Data 4 line signal level                      00000101b - Data 5 line signal level                      00000110b - Data 6 line signal level                      00000111b - Data 7 line signal level</p>
23 CLSL	<p>CMD Line Signal Level</p> <p>This status is used to check the CMD line level to recover from errors, and for debugging. The reset value is affected by the external pull-up / pull-down resistor, by default, the read value of this bit after reset is 1'b1, when the command line is pulled up.</p>
22-20 —	- Reserved
19 WPSP	<p>Write Protect Switch Pin Level</p> <p>The Write Protect Switch is supported for memory and combo cards. This bit reflects the inverted value of the WP pin of the card socket. A software reset does not affect this bit. The reset value is effected by the external write protect switch. If the WP pin is not used, it should be tied low, so that the reset value of this bit is high and write is enabled.</p> <p>0b - Write protected (WP = 1)                      1b - Write enabled (WP = 0)</p>
18	Card Detect Pin Level

Table continues on the next page...

Field	Function
CDPL	<p>This bit reflects the inverse value of the CD_B pin for the card socket. Debouncing is not performed on this bit. This bit may be valid, but is not guaranteed, because of propagation delay. Use of this bit is limited to testing since it must be debounced by software. A software reset does not effect this bit. A write to the Force Event Register does not effect this bit. The reset value is effected by the external card detection pin. This bit shows the value on the CD_B pin (i.e. when a card is inserted in the socket, it is 0 on the CD_B input, and consequently the CDPL reads 1.)</p> <p>0b - No card present (CD_B = 1) 1b - Card present (CD_B = 0)</p>
17 —	- Reserved
16 CINST	<p>Card Inserted</p> <p>This bit indicates whether a card has been inserted. The uSDHC debounces this signal so that the Host Driver will not need to wait for it to stabilize. Changing from a 0 to 1 generates a Card Insertion interrupt in the Interrupt Status register. Changing from a 1 to 0 generates a Card Removal interrupt in the Interrupt Status register. A write to the Force Event Register does not effect this bit.</p> <p>The Software Reset For All in the System Control register does not effect this bit. A software reset does not effect this bit.</p> <p>0b - Power on Reset or No Card 1b - Card Inserted</p>
15 TSCD	<p>Tape Select Change Done</p> <p>This bit indicates the dealy setting is effective after write CLK_TUNE_CTRL_STATUS register.</p> <p>0b - Delay cell select change is not finished. 1b - Delay cell select change is finished.</p>
14-13 —	- Reserved
12 RTR	<p>Re-Tuning Request (only for SD3.0 SDR104 mode and EMMC HS200 mode)</p> <p>Host Controller may request Host Driver to execute re-tuning sequence by setting this bit when the data window is shifted by temperature drift and a tuned sampling point does not have a good margin to receive correct data.</p> <p>This bit is cleared when a command is issued with setting Execute Tuning bit in MIXER_CTRL register.</p> <p>Changing of this bit from 0 to 1 generates Re-Tuning Event. Refer to Interrupt status registers for more detail.</p> <p>This bit isn't set to 1 if Sampling Clock Select in the MIXER_CTRL register is set to 0 (using fixed sampling clock).</p> <p>0b - Fixed or well tuned sampling clock 1b - Sampling clock needs re-tuning</p>
11 BREN	<p>Buffer Read Enable</p> <p>This status bit is used for non-DMA read transfers. The uSDHC implements an internal buffer to transfer data efficiently. This read only flag indicates that valid data exists in the host side buffer. If this bit is high, valid data greater than the watermark level exist in the buffer. A change of this bit from 1 to 0 occurs when some reads from the buffer(read DATPORT (Base + 0x20)) are made and the buffer hasn't valid data greater than the watermark level. A change of this bit from 0 to 1 occurs when there is enough valid data ready in the buffer and the Buffer Read Ready interrupt has been generated and enabled.</p> <p>0b - Read disable 1b - Read enable</p>
10	Buffer Write Enable

Table continues on the next page...

## uSDHC Memory Map/Register Definition

Field	Function
BWEN	<p>This status bit is used for non-DMA write transfers. The uSDHC implements an internal buffer to transfer data efficiently. This read only flag indicates if space is available for write data. If this bit is 1, valid data greater than the watermark level can be written to the buffer. A change of this bit from 1 to 0 occurs when some writes to the buffer(write DATPORT(Base + 0x20)) are made and the buffer hasn't valid space greater than the watermark level. A change of this bit from 0 to 1 occurs when the buffer can hold valid data greater than the write watermark level and the Buffer Write Ready interrupt is generated and enabled.</p> <p>0b - Write disable 1b - Write enable</p>
9 RTA	<p>Read Transfer Active</p> <p>This status bit is used for detecting completion of a read transfer.</p> <p>This bit is set for either of the following conditions:</p> <ul style="list-style-type: none"> <li>• After the end bit of the read command.</li> <li>• When writing a 1 to the Continue Request bit in the Protocol Control register to restart a read transfer.</li> </ul> <p>A Transfer Complete interrupt is generated when this bit changes to 0. This bit is cleared for either of the following conditions:</p> <ul style="list-style-type: none"> <li>• When the last data block as specified by block length is transferred to the System, i.e. all data are read away from uSDHC internal buffer.</li> <li>• When all valid data blocks have been transferred from uSDHC internal buffer to the System and no current block transfers are being sent as a result of the Stop At Block Gap Request being set to 1.</li> </ul> <p>0b - No valid data 1b - Transferring data</p>
8 WTA	<p>Write Transfer Active</p> <p>This status bit indicates a write transfer is active. If this bit is 0, it means no valid write data exists in the uSDHC.</p> <p>This bit is set in either of the following cases:</p> <ul style="list-style-type: none"> <li>• After the end bit of the write command.</li> <li>• When writing 1 to the Continue Request bit in the Protocol Control register to restart a write transfer.</li> </ul> <p>This bit is cleared in either of the following cases:</p> <ul style="list-style-type: none"> <li>• After getting the CRC status of the last data block as specified by the transfer count (Single and Multiple).</li> <li>• After getting the CRC status of any block where data transmission is about to be stopped by a Stop At Block Gap Request.</li> </ul> <p>During a write transaction, a Block Gap Event interrupt is generated when this bit is changed to 0, as result of the Stop At Block Gap Request being set. This status is useful for the Host Driver in determining when to issue commands during Write Busy state.</p> <p>0b - No valid data 1b - Transferring data</p>
7 SDOFF	<p>SD Clock Gated Off Internally</p> <p>This status bit indicates that the SD Clock is internally gated off, because of buffer over / under-run or read pause without read wait assertion, or the driver set FRC_SDCLK_ON bit is 0 to stop the SD clock in idle status. Set IPG_PERCLK_SOFT_EN and CARD_CLK_SOFT_EN to 0 also gate off SD clock. This bit is for the Host Driver to debug data transaction on the SD bus.</p> <p>0b - SD Clock is active.</p>

*Table continues on the next page...*

Field	Function
	1b - SD Clock is gated off.
6 PEROFF	<p>IPG_PERCLK Gated Off Internally</p> <p>This status bit indicates that the IPG_PERCLK is internally gated off. This bit is for the Host Driver to debug transaction on the SD bus. When IPG_CLK_SOFT_EN is cleared, IPG_PERCLK will be gated off, otherwise IPG_PERCLK will be always active.</p> <p>0b - IPG_PERCLK is active. 1b - IPG_PERCLK is gated off.</p>
5 HCKOFF	<p>HCLK Gated Off Internally</p> <p>This status bit indicates that the HCLK is internally gated off. This bit is for the Host Driver to debug during a data transfer.</p> <p>0b - HCLK is active. 1b - HCLK is gated off.</p>
4 IPGOFF	<p>IPG_CLK Gated Off Internally</p> <p>This status bit indicates that the ipg_clk is internally gated off. This bit is for the Host Driver to debug.</p> <p>0b - IPG_CLK is active. 1b - IPG_CLK is gated off.</p>
3 SDSTB	<p>SD Clock Stable</p> <p>This status bit indicates that the internal card clock is stable. This bit is for the Host Driver to poll clock status when changing the clock frequency. It is recommended to clear FRC_SDCLK_ON bit in System Control register to remove glitches on the card clock when the frequency is changing.</p> <p><i>Before changing clock divisor value(SDCLKFS or DVS), Host Driver should make sure the SDSTB bit is high.</i></p> <p>0b - Clock is changing frequency and not stable. 1b - Clock is stable.</p>
2 DLA	<p>Data Line Active</p> <p>This status bit indicates whether one of the DATA lines on the SD Bus is in use.</p> <p>In the case of read transactions:</p> <p>This status indicates if a read transfer is executing on the SD Bus. Changes in this value from 1 to 0, between data blocks, generates a Block Gap Event interrupt in the Interrupt Status register.</p> <p>This bit will be set in either of the following cases:</p> <ul style="list-style-type: none"> <li>• After the end bit of the read command.</li> <li>• When writing a 1 to the Continue Request bit in the Protocol Control register to restart a read transfer.</li> </ul> <p>This bit will be cleared in either of the following cases:</p> <p>(1) When the end bit of the last data block is sent from the SD Bus to the uSDHC.</p> <p>(2) When the Read Wait state is stopped by a Suspend command and the DATA2 line is released.</p> <p>The uSDHC will wait at the next block gap by driving Read Wait at the start of the interrupt cycle. If the Read Wait signal is already driven (data buffer cannot receive data), the uSDHC can wait for a current block gap by continuing to drive the Read Wait signal. It is necessary to support Read Wait in order to use the suspend / resume function. This bit will remain 1 during Read Wait.</p> <p>In the case of write transactions:</p> <p>This status indicates that a write transfer is executing on the SD Bus. Changes in this value from 1 to 0 generate a Transfer Complete interrupt in the Interrupt Status register.</p> <p>This bit will be set in either of the following cases:</p>

*Table continues on the next page...*

## uSDHC Memory Map/Register Definition

Field	Function
	<ul style="list-style-type: none"> <li>• After the end bit of the write command.</li> <li>• When writing to 1 to the Continue Request bit in the Protocol Control register to continue a write transfer.</li> </ul> <p>This bit will be cleared in either of the following cases:</p> <ul style="list-style-type: none"> <li>• When the SD card releases Write Busy of the last data block, the uSDHC will also detect if the output is not busy. If the SD card does not drive the busy signal after the CRC status is received, the uSDHC shall assume the card drive "Not Busy".</li> <li>• When the SD card releases write busy, prior to waiting for write transfer, and as a result of a Stop At Block Gap Request.</li> </ul> <p>In the case of command with busy pending:</p> <p>This status indicates that a busy state follows the command and the data line is in use. This bit will be cleared when the DATA0 line is released.</p> <p>0b - DATA Line Inactive 1b - DATA Line Active</p>
1 CDIHB	<p>Command Inhibit (DATA)</p> <p>This status bit is generated if either the DAT Line Active or the Read Transfer Active is set to 1. If this bit is 0, it indicates that the uSDHC can issue the next SD / MMC Command. Commands with a busy signal belong to Command Inhibit (DATA) (for example. R1b, R5b type). Changing from 1 to 0 generates a Transfer Complete interrupt in the Interrupt Status register.</p> <p><b>NOTE:</b> The SD Host Driver can save registers for a suspend transaction after this bit has changed from 1 to 0.</p> <p>0b - Can issue command which uses the DATA line 1b - Cannot issue command which uses the DATA line</p>
0 CIHB	<p>Command Inhibit (CMD)</p> <p>If this status bit is 0, it indicates that the CMD line is not in use and the uSDHC can issue a SD / MMC Command using the CMD line.</p> <p>This bit is set also immediately after the Transfer Type register is written. This bit is cleared when the command response is received. Even if the Command Inhibit (DATA) is set to 1, Commands using only the CMD line can be issued if this bit is 0. Changing from 1 to 0 generates a Command Complete interrupt in the Interrupt Status register. If the uSDHC cannot issue the command because of a command conflict error (Refer to Command CRC Error) or because of a Command Not Issued By Auto CMD12 Error, this bit will remain 1 and the Command Complete is not set. The Status of issuing an Auto CMD12 does not show on this bit.</p> <p>0b - Can issue command using only CMD line 1b - Cannot issue command</p>

### 25.9.1.12 Protocol Control (PROT\_CTRL)

#### 25.9.1.12.1 Offset

Register	Offset
PROT_CTRL	28h

### 25.9.1.12.2 Function

There are three cases to restart the transfer after stop at the block gap. Which case is appropriate depends on whether the uSDHC issues a Suspend command or the SD card accepts the Suspend command.

1. If the Host Driver does not issue a Suspend command, the Continue Request shall be used to restart the transfer.
2. If the Host Driver issues a Suspend command and the SD card accepts it, a Resume command shall be used to restart the transfer.
3. If the Host Driver issues a Suspend command and the SD card does not accept it, the Continue Request shall be used to restart the transfer.

Any time Stop At Block Gap Request stops the data transfer, the Host Driver shall wait for a Transfer Complete (in the Interrupt Status register), before attempting to restart the transfer. When restarting the data transfer by Continue Request, the Host Driver shall clear the Stop At Block Gap Request before or simultaneously.

Field	Function
31	-
—	Reserved. Always write as 0

Table continues on the next page...

## uSDHC Memory Map/Register Definition

Field	Function
30 NON_EXACT_BLK_RD	<p>NON_EXACT_BLK_RD</p> <p>Current block read is non-exact block read. It is only used for SDIO.</p> <p>0b - The block read is exact block read. Host driver doesn't need to issue abort command to terminate this multi-block read. 1b - The block read is non-exact block read. Host driver needs to issue abort command to terminate this multi-block read.</p>
29-27 BURST_LEN_EN	<p>BURST length enable for INCR, INCR4 / INCR8 / INCR16, INCR4-WRAP / INCR8-WRAP / INCR16-WRAP</p> <p>This is used to enable / disable the burst length for the external AHB2AXI bridge. It is useful especially for INCR transfer because without burst length indicator, the AHB2AXI bridge does not know the burst length in advance. Without burst length indicator, AHB INCR transfers can only be converted to SINGLES on the AXI side.</p> <p>1xxb - Burst length is enabled for INCR4-WRAP / INCR8-WRAP / INCR16-WRAP x1xb - Burst length is enabled for INCR4 / INCR8 / INCR16 xx1b - Burst length is enabled for INCR</p>
26 WECRM	<p>Wakeup Event Enable On SD Card Removal</p> <p>This bit enables a wakeup event, via a Card Removal, in the Interrupt Status register. FN_WUS (Wake Up Support) in CIS does not effect this bit. When this bit is set, the Card Removal Status and the uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active in order to assert the Card Removal Status and the uSDHC interrupt.</p> <p>0b - Disable 1b - Enable</p>
25 WECINS	<p>Wakeup Event Enable On SD Card Insertion</p> <p>This bit enables a wakeup event, via a Card Insertion, in the Interrupt Status register. FN_WUS (Wake Up Support) in CIS does not effect this bit. When this bit is set, the Card Insertion Status and the uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active in order to assert the Card Insertion Status and the uSDHC interrupt.</p> <p>0b - Disable 1b - Enable</p>
24 WECINT	<p>Wakeup Event Enable On Card Interrupt</p> <p>This bit enables a wakeup event, via a Card Interrupt, in the Interrupt Status register. This bit can be set to 1 if FN_WUS (Wake Up Support) in CIS is set to 1. When this bit is set, the Card Interrupt Status and the uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active in order to assert the Card Interrupt Status and the uSDHC interrupt.</p> <p>0b - Disable 1b - Enable</p>
23-21 —	<p>-</p> <p>Reserved. Always write as 3'b100</p>
20 RD_DONE_NO_8CLK	<p>RD_DONE_NO_8CLK</p> <p><i>Read done no 8 clock:</i></p> <p><i>According to the SD/MMC spec, for read data transaction, 8 clocks are needed after the end bit of the last data block. So, by default(RD_DONE_NO_8CLK=0), 8 clocks will be active after the end bit of the last read data transaction.</i></p> <p><i>However, this 8 clocks should not be active if user wants to use stop at block gap(include the auto stop at block gap in boot mode) feature for read and the RWCTL bit(bit18) is not enabled. In this case, software should set RD_DONE_NO_8CLK to avoid this 8 clocks. Otherwise, the device may send extra data to uSDHC while uSDHC ignores these data.</i></p>

Table continues on the next page...

Field	Function
	<i>In a summary, this bit should be set only if the use case needs to use stop at block gap feature while the device can't support the read wait feature.</i>
19 IABG	<p>Interrupt At Block Gap</p> <p>This bit is valid only in 4-bit mode, of the SDIO card, and selects a sample point in the interrupt cycle. Setting to 1 enables interrupt detection at the block gap for a multiple block transfer. Setting to 0 disables interrupt detection during a multiple block transfer. If the SDIO card cannot signal an interrupt during a multiple block transfer, this bit should be set to 0 to avoid an inadvertent interrupt. When the Host Driver detects an SDIO card insertion, it shall set this bit according to the CCCR of the card.</p> <p>0b - Disabled 1b - Enabled</p>
18 RWCTL	<p>Read Wait Control</p> <p>The read wait function is optional for SDIO cards. If the card supports read wait, set this bit to enable use of the read wait protocol to stop read data using the DATA2 line. Otherwise the uSDHC has to stop the SD Clock to hold read data, which restricts commands generation. When the Host Driver detects an SDIO card insertion, it shall set this bit according to the CCCR of the card. If the card does not support read wait, this bit shall never be set to 1, otherwise DATA line conflicts may occur. If this bit is set to 0, stop at block gap during read operation is also supported, but the uSDHC will stop the SD Clock to pause reading operation.</p> <p>0b - Disable Read Wait Control, and stop SD Clock at block gap when SABGREQ bit is set 1b - Enable Read Wait Control, and assert Read Wait without stopping SD Clock at block gap when SABGREQ bit is set</p>
17 CREQ	<p>Continue Request</p> <p>This bit is used to restart a transaction which was stopped using the Stop At Block Gap Request. When a Suspend operation is not accepted by the card, it is also by setting this bit to restart the paused transfer. To cancel stop at the block gap, set Stop At Block Gap Request to 0 and set this bit to 1 to restart the transfer.</p> <p>The uSDHC automatically clears this bit, therefore it is not necessary for the Host Driver to set this bit to 0. If both Stop At Block Gap Request and this bit are 1, the continue request is ignored.</p> <p>0b - No effect 1b - Restart</p>
16 SABGREQ	<p>Stop At Block Gap Request</p> <p>This bit is used to stop executing a transaction at the next block gap for both DMA and non-DMA transfers. Until the Transfer Complete is set to 1, indicating a transfer completion, the Host Driver shall leave this bit set to 1. Clearing both the Stop At Block Gap Request and Continue Request does not cause the transaction to restart. Read Wait is used to stop the read transaction at the block gap. The uSDHC will honor the Stop At Block Gap Request for write transfers, but for read transfers it requires that the SDIO card support Read Wait. Therefore, the Host Driver shall not set this bit during read transfers unless the SDIO card supports Read Wait and has set the Read Wait Control to 1, otherwise the uSDHC will stop the SD bus clock to pause the read operation during block gap. In the case of write transfers in which the Host Driver writes data to the Data Port register, the Host Driver shall set this bit after all block data is written. If this bit is set to 1, the Host Driver shall not write data to the Data Port register after a block is sent. Once this bit is set, the Host Driver shall not clear this bit before the Transfer Complete bit in Interrupt Status Register is set, otherwise the uSDHCs behavior is undefined.</p> <p>This bit effects Read Transfer Active, Write Transfer Active, DATA Line Active and Command Inhibit (DATA) in the Present State register.</p> <p>0b - Transfer 1b - Stop</p>
15-10 —	- Reserved

9-8 DMASEL	<p>DMA Select</p> <p>This field is valid while DMA (SDMA or ADMA) is enabled and selects the DMA operation.</p> <p>00b - No DMA or Simple DMA is selected            01b - ADMA1 is selected            10b - ADMA2 is selected            11b - reserved</p>
7 CDSS	<p>Card Detect Signal Selection</p> <p>This bit selects the source for the card detection.</p> <p>0b - Card Detection Level is selected (for normal purpose).            1b - Card Detection Test Level is selected (for test purpose).</p>
6 CDTL	<p>Card Detect Test Level</p> <p>This bit is enabled while the Card Detection Signal Selection is set to 1 and it indicates card insertion.</p> <p>0b - Card Detect Test Level is 0, no card inserted            1b - Card Detect Test Level is 1, card inserted</p>
5-4 EMODE	<p>Endian Mode</p> <p>The uSDHC supports all three endian modes in data transfer. Refer to <a href="#">Data Buffer</a> for more details.</p> <p>00b - Big Endian Mode            01b - Half Word Big Endian Mode            10b - Little Endian Mode            11b - Reserved</p>
3 D3CD	<p>DATA3 as Card Detection Pin</p> <p>If this bit is set, DATA3 should be pulled down to act as a card detection pin. Be cautious when using this feature, because DATA3 is also a chip-select for the SPI mode. A pull-down on this pin and CMD0 may set the card into the SPI mode, which the uSDHC does not support.</p> <p>0b - DATA3 does not monitor Card Insertion            1b - DATA3 as Card Detection Pin</p>
2-1 DTW	<p>Data Transfer Width</p> <p>This bit selects the data width of the SD bus for a data transfer. The Host Driver shall set it to match the data width of the card. Possible Data transfer Width is 1-bit, 4-bits or 8-bits.</p> <p>00b - 1-bit mode            01b - 4-bit mode            10b - 8-bit mode            11b - Reserved</p>
0 LCTL	<p>LED Control</p> <p>This bit, fully controlled by the Host Driver, is used to caution the user not to remove the card while the card is being accessed. If the software is going to issue multiple SD commands, this bit can be set during all these transactions. It is not necessary to change for each transaction. When the software issues multiple SD commands, setting the bit once before the first command is sufficient: it is not necessary to reset the bit between commands.</p> <p>0b - LED off            1b - LED on</p>

## 25.9.1.13 System Control (SYS\_CTRL)

### 25.9.1.13.1 Offset

Register	Offset
SYS_CTRL	2Ch

### 25.9.1.13.2 Diagram

### 25.9.1.13.3 Fields

Field	Function
31-29 —	- Reserved
28 RSTT	Reset Tuning When set this bit to 1, it will reset tuning circuit. After tuning circuits are reset, bit value is 0. Clearing execute_tuning bit in AUTOCMD12_ERR_STATUS will also set this bit to 1 to reset tuning circuit
27 INITA	Initialization Active When this bit is set, 80 SD-Clocks are sent to the card. After the 80 clocks are sent, this bit is self cleared. This bit is very useful during the card power-up period when 74 SD-Clocks are needed and the clock auto gating feature is enabled. Writing 1 to this bit when this bit is already 1 has no effect. Writing 0 to this bit at any time has no effect. When either of the CIHB and CDIHB bits in the Present State Register are set, writing 1 to this bit is ignored (i.e. when command line or data lines are active, write to this bit is not allowed). On the otherhand, when this bit is set, i.e., during intialization active period, it is allowed to issue command, and the command bit stream will appear on the CMD pad after all 80 clock cycles are done. So when this command ends, the driver can make sure the 80 clock cycles are sent out. This is very useful when the driver needs send 80 cycles to the card and does not want to wait till this bit is self cleared.
26	Software Reset For DATA Line

20 —	- Reserved
19-16 DTCV	<p>Data Timeout Counter Value</p> <p>This value determines the interval by which DAT line timeouts are detected. Refer to the Data Timeout Error bit in the Interrupt Status register for information on factors that dictate time-out generation. Time-out clock frequency will be generated by dividing the base clock SDCLK value by this value.</p> <p>The Host Driver can clear the Data Timeout Error Status Enable (in the Interrupt Status Enable register) to prevent inadvertent time-out events.</p> <p>0000b - SDCLK x 2<sup>14</sup>  0001b - SDCLK x 2<sup>15</sup>  1101b - SDCLK x 2<sup>27</sup>  1110b - SDCLK x 2<sup>28</sup>  1111b - SDCLK x 2<sup>29</sup></p>
15-8 SDCLKFS	<p>SDCLK Frequency Select</p> <p>This register is used to select the frequency of the SDCLK pin. The frequency is not programmed directly, rather this register holds the prescaler (this register) and divisor (next register) of the Base Clock Frequency register.</p> <p><i>In Single Data Rate mode(DDR_EN bit of MIXERCTRL is '0')</i></p> <p>Only the following settings are allowed:</p> <p>80h) Base clock divided by 256  40h) Base clock divided by 128  20h) Base clock divided by 64  10h) Base clock divided by 32  08h) Base clock divided by 16  04h) Base clock divided by 8  02h) Base clock divided by 4  01h) Base clock divided by 2  00h) Base clock divided by 1</p> <p><i>While in Dual Data Rate mode(DDR_EN bit of MIXERCTRL is '1')</i></p> <p>Only the following settings are allowed:</p> <p>80h) Base clock divided by 512  40h) Base clock divided by 256  20h) Base clock divided by 128  10h) Base clock divided by 64  08h) Base clock divided by 32  04h) Base clock divided by 16  02h) Base clock divided by 8  01h) Base clock divided by 4  00h) Base clock divided by 2</p> <p><i>When S/W changes the DDR_EN bit, SDCLKFS may need to be changed also!</i></p> <p>In Single Data Rate mode, setting 00h bypasses the frequency prescaler of the SD Clock.</p>

*Table continues on the next page...*

Field	Function
	<p>Multiple bits must not be set, or the behavior of this prescaler is undefined. The two default divider values can be calculated by the frequency of ipg_perclk and the following Divisor bits.</p> <p>The frequency of SDCLK is set by the following formula:                      Clock Frequency = (Base Clock) / (prescaler x divisor)</p> <p>For example, in Single Data Rate mode, if the Base Clock Frequency is 96 MHz, and the target frequency is 25 MHz, then choosing the prescaler value of 01h and divisor value of 1h will yield 24 MHz, which is the nearest frequency less than or equal to the target. Similarly, to approach a clock value of 400 kHz, the prescaler value of 08h and divisor value of eh yields the exact clock value of 400 kHz.</p> <p>The reset value of this bit field is 80h, so if the input Base Clock (ipg_perclk) is about 96 MHz, the default SD Clock after reset is 375 kHz.</p> <p>According to the SD Physical Specification Version 1.1 and the SDIO Card Specification Version 1.2, the maximum SD Clock frequency is 50 MHz and shall never exceed this limit.</p> <p><i>Before changing clock divisor value(SDCLKFS or DVS), Host Driver should make sure the SDSTB bit is high.</i></p> <p><i>If setting SDCLKFS and DVS can generate same clock frequency,(For example, in SDR mode, SDCLKFS = 01h is same as DVS = 01h.) SDCLKFS is highly recommended.</i></p>
7-4 DVS	<p>Divisor</p> <p>This register is used to provide a more exact divisor to generate the desired SD clock frequency. Note the divider can even support odd divisors without deterioration of duty cycle.</p> <p><i>Before changing clock divisor value(SDCLKFS or DVS), Host Driver should make sure the SDSTB bit is high.</i></p> <p>The setting are as following:</p> <ul style="list-style-type: none"> <li>0000b - Divide-by-1</li> <li>0001b - Divide-by-2</li> <li>1110b - Divide-by-15</li> <li>1111b - Divide-by-16</li> </ul>
3-0 —	<p>-</p> <p>Reserved. Always write as 1.</p>

## 25.9.1.14 Interrupt Status (INT\_STATUS)

### 25.9.1.14.1 Offset

Register	Offset
INT_STATUS	30h

### 25.9.1.14.2 Function

An interrupt is generated when the Normal Interrupt Signal Enable is enabled and at least one of the status bits is set to 1. For all bits, writing 1 to a bit clears it; writing to 0 keeps the bit unchanged. More than one status can be cleared with a single register write. For

Card Interrupt, before writing 1 to clear, it is required that the card stops asserting the interrupt, meaning that when the Card Driver services the interrupt condition, otherwise the CINT bit will be asserted again.

The table below shows the relationship between the Command Timeout Error and the Command Complete.

**Table 25-9. uSDHC Status for Command Timeout Error/Command Complete Bit Combinations**

Command Complete	Command Timeout Error	Meaning of the Status
0	0	X
X	1	Response not received within 64 SDCLK cycles
1	0	Response received

The table below shows the relationship between the Transfer Complete and the Data Timeout Error.

**Table 25-10. uSDHC Status for Data Timeout Error/Transfer Complete Bit Combinations**

Transfer Complete	Data Timeout Error	Meaning of the Status
0	0	X
0	1	Timeout occurred during transfer
1	X	Data Transfer Complete

The table below shows the relationship between the Command CRC Error and Command Timeout Error.

**Table 25-11. uSDHC Status for Command CRC Error/Command Timeout Error Bit Combinations**

Command Complete	Command Timeout Error	Meaning of the Status
0	0	No error
0	1	Response Timeout Error
1	0	Response CRC Error
1	1	CMD line conflict

### 25.9.1.14.3 Diagram

### 25.9.1.14.4 Fields

Field	Function
31-29 —	- Reserved
28 DMAE	DMA Error Occurs when an Internal DMA transfer has failed. This bit is set to 1, when some error occurs in the data transfer. This error can be caused by either Simple DMA or ADMA, depending on which DMA is in use. The value in DMA System Address register is the next fetch address where the error occurs. Since any error corrupts the whole data block, the Host Driver shall re-start the transfer from the corrupted block boundary. The address of the block boundary can be calculated either from the current DS_ADDR value or from the remaining number of blocks and the block size.  0b - No Error 1b - Error
27 —	- Reserved
26 TNE	Tuning Error: (only for SD3.0 SDR104 mode and EMMC HS200 mode) This bit is set when an unrecoverable error is detected in a tuning circuit. By detecting Tuning Error, Host Driver needs to abort a command executing and perform tuning.
25 —	- Reserved
24 AC12E	Auto CMD12 Error Occurs when detecting that one of the bits in the Auto CMD12 Error Status register has changed from 0 to 1. This bit is set to 1, not only when the errors in Auto CMD12 occur, but also when the Auto CMD12 is not executed due to the previous command error.  0b - No Error 1b - Error
23	-

Table continues on the next page...

Field	Function

21 DCE	<p>Data CRC Error</p> <p>Occurs when detecting a CRC error when transferring read data, which uses the DATA line, or when detecting the Write CRC status having a value other than 010.</p> <p>This bit will be not asserted in tuning process.</p> <p>0b - No Error 1b - Error</p>
20 DTOE	<p>Data Timeout Error</p> <p>Occurs when detecting one of following time-out conditions.</p> <ul style="list-style-type: none"> <li>• Busy time-out for R1b, R5b type</li> <li>• Busy time-out after Write CRC status</li> <li>• Read Data time-out.</li> </ul> <p>This bit will be not asserted in tuning process.</p> <p>0b - No Error 1b - Time out</p>
19 CIE	<p>Command Index Error</p> <p>Occurs if a Command Index error occurs in the command response.</p> <p>This bit will be not asserted in tuning process.</p> <p>0b - No Error 1b - Error</p>
18 CEBE	<p>Command End Bit Error</p> <p>Occurs when detecting that the end bit of a command response is 0.</p> <p>This bit will be not asserted in tuning process.</p> <p>0b - No Error 1b - End Bit Error Generated</p>
17 CCE	<p>Command CRC Error</p> <p>Command CRC Error is generated in two cases.</p> <ul style="list-style-type: none"> <li>• If a response is returned and the Command Timeout Error is set to 0 (indicating no time-out), this bit is set when detecting a CRC error in the command response.</li> <li>• The uSDHC detects a CMD line conflict by monitoring the CMD line when a command is issued. If the uSDHC drives the CMD line to 1, but detects 0 on the CMD line at the next SDCLK edge, then the uSDHC shall abort the command (Stop driving CMD line) and set this bit to 1. The Command Timeout Error shall also be set to 1 to distinguish CMD line conflict.</li> </ul> <p>This bit will be not asserted in tuning process.</p> <p>0b - No Error 1b - CRC Error Generated.</p>
16	Command Timeout Error

*Table continues on the next page...*

## uSDHC Memory Map/Register Definition

Field	Function
CTOE	Occurs only if no response is returned within 64 SDCLK cycles from the end bit of the command. If the uSDHC detects a CMD line conflict, in which case a Command CRC Error shall also be set (as shown in <a href="#">Interrupt Status (INT_STATUS)</a> ), this bit shall be set without waiting for 64 SDCLK cycles. This is because the command will be aborted by the uSDHC.  This bit will be not asserted in tuning process.  0b - No Error 1b - Time out
15 —	- Reserved
14 TP	Tuning Pass:(only for SD3.0 SDR104 mode and EMMC HS200 mode) Current CMD19 transfer is done successfully. That is, current sampling point is correct.
13 —	- Reserved
12 RTE	Re-Tuning Event: (only for SD3.0 SDR104 mode and EMMC HS200 mode) This status is set if Re-Tuning Request in the Present State register changes from 0 to 1. Host Controller requests Host Driver to perform re-tuning for next data transfer. Current data transfer (not large block count) can be completed without re-tuning.  0b - Re-Tuning is not required 1b - Re-Tuning should be performed
11-9 —	- Reserved
8 CINT	Card Interrupt This status bit is set when an interrupt signal is detected from the external card. In 1-bit mode, the uSDHC will detect the Card Interrupt without the SD Clock to support wakeup. In 4-bit mode, the card interrupt signal is sampled during the interrupt cycle, so the interrupt from card can only be sampled during interrupt cycle, introducing some delay between the interrupt signal from the SDIO card and the interrupt to the Host System. Writing this bit to 1 can clear this bit, but as the interrupt source from the SDIO card does not clear, this bit is set again. In order to clear this bit, it is required to reset the interrupt source from the external card followed by a writing 1 to this bit.  When this status has been set, and the Host Driver needs to service this interrupt, the Card Interrupt Signal Enable in the Interrupt Signal Enable register should be 0 to stop driving the interrupt signal to the Host System. After completion of the card interrupt service (It should reset the interrupt sources in the SDIO card and the interrupt signal may not be asserted), write 1 to clear this bit, set the Card Interrupt Signal Enable to 1, and start sampling the interrupt signal again.  0b - No Card Interrupt 1b - Generate Card Interrupt
7 CRM	Card Removal This status bit is set if the Card Inserted bit in the Present State register changes from 1 to 0. When the Host Driver writes this bit to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed. Because the card state may possibly be changed when the Host Driver clears this bit and the interrupt event may not be generated. When this bit is cleared, it will be set again if no card is inserted. In order to leave it cleared, clear the Card Removal Status Enable bit in Interrupt Status Enable register.  0b - Card state unstable or inserted 1b - Card removed
6 CINS	Card Insertion

*Table continues on the next page...*

Field	Function
	<p>This status bit is set if the Card Inserted bit in the Present State register changes from 0 to 1. When the Host Driver writes this bit to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed. Because the card state may possibly be changed when the Host Driver clears this bit and the interrupt event may not be generated. When this bit is cleared, it will be set again if a card is inserted. In order to leave it cleared, clear the Card Inserted Status Enable bit in Interrupt Status Enable register.</p> <p>0b - Card state unstable or removed 1b - Card inserted</p>
5 BRR	<p>Buffer Read Ready</p> <p>This status bit is set if the Buffer Read Enable bit, in the Present State register, changes from 0 to 1. Refer to the Buffer Read Enable bit in the Present State register for additional information.</p> <p>This bit indicates that cmd19 is finished in tuning process.</p> <p>0b - Not ready to read buffer 1b - Ready to read buffer</p>
4 BWR	<p>Buffer Write Ready</p> <p>This status bit is set if the Buffer Write Enable bit, in the Present State register, changes from 0 to 1. Refer to the Buffer Write Enable bit in the Present State register for additional information.</p> <p>0b - Not ready to write buffer 1b - Ready to write buffer:</p>
3 DINT	<p>DMA Interrupt</p> <p>Occurs only when the internal DMA finishes the data transfer successfully. Whenever errors occur during data transfer, this bit will not be set. Instead, the DMAE bit will be set. Either Simple DMA or ADMA finishes data transferring, this bit will be set.</p> <p>0b - No DMA Interrupt 1b - DMA Interrupt is generated</p>
2 BGE	<p>Block Gap Event</p> <p>If the Stop At Block Gap Request bit in the Protocol Control register is set, this bit is set when a read or write transaction is stopped at a block gap. If Stop At Block Gap Request is not set to 1, this bit is not set to 1.</p> <p>In the case of a Read Transaction: This bit is set at the falling edge of the DATA Line Active Status (When the transaction is stopped at SD Bus timing). The Read Wait must be supported in order to use this function.</p> <p>In the case of Write Transaction: This bit is set at the falling edge of Write Transfer Active Status (After getting CRC status at SD Bus timing).</p> <p>0b - No block gap event 1b - Transaction stopped at block gap</p>
1 TC	<p>Transfer Complete</p> <p>This bit is set when a read or write transfer is completed.</p> <p>In the case of a Read Transaction: This bit is set at the falling edge of the Read Transfer Active Status. There are two cases in which this interrupt is generated. The first is when a data transfer is completed as specified by the data length (after the last data has been read to the Host System). The second is when data has stopped at the block gap and completed the data transfer by setting the Stop At Block Gap Request bit in the Protocol Control register (after valid data has been read to the Host System).</p> <p>In the case of a Write Transaction: This bit is set at the falling edge of the DATA Line Active Status. There are two cases in which this interrupt is generated. The first is when the last data is written to the SD card as specified by the data length and the busy signal is released. The second is when data transfers are</p>

Field	Function
	<p>stopped at the block gap, by setting the Stop At Block Gap Request bit in the Protocol Control register, and the data transfers are completed. (after valid data is written to the SD card and the busy signal released).</p> <p>In the case of a command with busy, this bit is set when busy is deasserted.</p> <p>This bit will be not asserted in tuning process.</p> <p>0b - Transfer not complete 1b - Transfer complete</p>
0 CC	<p>Command Complete</p> <p>This bit is set when you receive the end bit of the command response (except Auto CMD12). Refer to the Command Inhibit (CMD) in the Present State register.</p> <p>This bit will be not asserted in tuning process.</p> <p>0b - Command not complete 1b - Command complete</p>

### 25.9.1.15 Interrupt Status Enable (INT\_STATUS\_EN)

#### 25.9.1.15.1 Offset

Register	Offset
INT_STATUS_EN	34h

#### 25.9.1.15.2 Function

Setting the bits in this register to 1 enables the corresponding Interrupt Status to be set by the specified event. If any bit is cleared, the corresponding Interrupt Status bit is also cleared (i.e. when the bit in this register is cleared, the corresponding bit in Interrupt Status Register is always 0).

- Depending on IABG bit setting, uSDHC may be programmed to sample the card interrupt signal during the interrupt period and hold its value in the flip-flop. There will be some delays on the Card Interrupt, asserted from the card, to the time the Host System is informed.
- To detect a CMD line conflict, the Host Driver must set both Command Timeout Error Status Enable and Command CRC Error Status Enable to 1.

### 25.9.1.17 Auto CMD12 Error Status (AUTOCMD12\_ERR\_STATUS)

#### 25.9.1.17.1 Offset

Register	Offset
AUTOCMD12_ERR_ST ATUS	3Ch

### 25.9.1.17.2 Function

When the Auto CMD12 Error Status bit in the Status register is set, the Host Driver shall check this register to identify what kind of error the Auto CMD12 / CMD 23 indicated. Auto CMD23 errors are indicated in bit 04-01. This register is valid only when the Auto CMD12 Error status bit is set.

The table below shows the relationship between the Auto CMD12 CRC Error and the Auto CMD12 Command Timeout Error.

**Table 25-12. Relationship Between Command CRC Error and Command Timeout Error for Auto CMD12**

Auto CMD12 CRC Error	Auto CMD12 Timeout Error	Type of Error
0	0	No Error
0	1	Response Timeout Error
1	0	Response CRC Error
1	1	CMD line conflict

Changes in Auto CMD12 Error Status register can be classified in three scenarios:

1. When the uSDHC is going to issue an Auto CMD12.
  - Set bit 0 to 1 if the Auto CMD12 can't be issued due to an error in the previous command
  - Set bit 0 to 0 if the Auto CMD12 is issued
2. At the end bit of an Auto CMD12 response.
  - Check errors correspond to bits 1-4.
  - Set bits 1-4 corresponding to detected errors.
  - Clear bits 1-4 corresponding to detected errors
3. Before reading the Auto CMD12 Error Status bit 7.
  - Set bit 7 to 1 if there is a command that can't be issued
  - Clear bit 7 if there is no command to issue

The timing for generating the Auto CMD12 Error and writing to the Command register are asynchronous. After that, bit 7 shall be sampled when the driver is not writing to the Command register. So it is suggested to read this register only when the AC12E bit in Interrupt Status register is set. An Auto CMD12 Error Interrupt is generated when one of the error bits (0-4) is set to 1. The Command Not Issued By Auto CMD12 Error does not generate an interrupt.

## 25.9.1.17.3 Diagram

## 25.9.1.17.4 Fields

Field	Function
31-24 —	- Reserved
23 SMP_CLK_SEL	Sample Clock Select When std_tuning_en bit is set, this bit is used to select sampling clock to receive CMD and DATA. Otherwise, this bit is reserved. This bit is set by ty tuning procedure and valid after the completion of tuning(When Execute Tuning is cleared). Setting 1 means that tuning is completed successfully and setting 0 means that tuning is failed. Writing 1 to this bit is meaningless and ignored. A tuning circuit is reset by writing to 0. This bit can be cleared with setting Execute Tuning. Once the tuning circuit is reset, it will take time to complete tuning sequence. Therefore, Host Driver should keep this bit to 1 to perform re-tuning sequence to complete re-tuning sequence in a short time. Change of this bit is not allowed while the Host controller us receiving response or a read data block.  0b - Fixed clock is used to sample data 1b - Tuned clock is used to sample data
22 EXECUTE_TUNING	Execute Tuning When std_tuning_en bit is set, this bit is used to start tuning procedure. Otherwise, this bit is reserved. This bit is set to start tuning procedure and automatically cleared when runing procedure is completed. The result of tuning is indicated to sam_clk_sel bit. Tuning procedure is aborted by writing 0.
21-8 —	- Reserved
7 CNIBAC12E	Command Not Issued By Auto CMD12 Error Setting this bit to 1 means CMD_wo_DAT is not executed due to an Auto CMD12 Error (D04-D01) in this register.

Table continues on the next page...

Field	Function
	0b - No error 1b - Not Issued
6-5 —	- Reserved
4 AC12IE	Auto CMD12 / 23 Index Error Occurs if the Command Index error occurs in response to a command.  0b - No error 1b - Error, the CMD index in response is not CMD12/23
3 AC12CE	Auto CMD12 / 23 CRC Error Occurs when detecting a CRC error in the command response.  0b - No CRC error 1b - CRC Error Met in Auto CMD12/23 Response
2 AC12EBE	Auto CMD12 / 23 End Bit Error Occurs when detecting that the end bit of command response is 0 which should be 1.  0b - No error 1b - End Bit Error Generated
1 AC12TOE	Auto CMD12 / 23 Timeout Error Occurs if no response is returned within 64 SDCLK cycles from the end bit of the command. If this bit is set to 1, the other error status bits (2-4) have no meaning.  0b - No error 1b - Time out
0 AC12NE	Auto CMD12 Not Executed If memory multiple block data transfer is not started, due to a command error, this bit is not set because it is not necessary to issue an Auto CMD12. Setting this bit to 1 means the uSDHC cannot issue the Auto CMD12 to stop a memory multiple block data transfer due to some error. If this bit is set to 1, other error status bits (1-4) have no meaning.  0b - Executed 1b - Not executed

## 25.9.1.18 Host Controller Capabilities (HOST\_CTRL\_CAP)

### 25.9.1.18.1 Offset

Register	Offset
HOST_CTRL_CAP	40h

### 25.9.1.18.2 Function

This register provides the Host Driver with information specific to the uSDHC implementation. The value in this register is the power-on-reset value, and does not change with a software reset.

### 25.9.1.18.3 Diagram

### 25.9.1.18.4 Fields

Field	Function
31-27 —	- Reserved
26 VS18	Voltage Support 1.8 V This bit shall depend on the Host System ability. 0b - 1.8V not supported 1b - 1.8V supported
25 VS30	Voltage Support 3.0 V This bit shall depend on the Host System ability. 0b - 3.0V not supported 1b - 3.0V supported
24 VS33	Voltage Support 3.3V This bit shall depend on the Host System ability. 0b - 3.3V not supported

Table continues on the next page...

## uSDHC Memory Map/Register Definition

Field	Function
	1b - 3.3V supported
23 SRS	Suspend / Resume Support This bit indicates whether the uSDHC supports Suspend / Resume functionality. If this bit is 0, the Suspend and Resume mechanism, as well as the Read Wait, are not supported, and the Host Driver shall not issue either Suspend or Resume commands.  0b - Not supported 1b - Supported
22 DMAS	DMA Support This bit indicates whether the uSDHC is capable of using the internal DMA to transfer data between system memory and the data buffer directly.  0b - DMA not supported 1b - DMA Supported
21 HSS	High Speed Support This bit indicates whether the uSDHC supports High Speed mode and the Host System can supply a SD Clock frequency from 25 MHz to 50 MHz.  0b - High Speed Not Supported 1b - High Speed Supported
20 ADMAS	ADMA Support This bit indicates whether the uSDHC supports the ADMA feature.  0b - Advanced DMA Not supported 1b - Advanced DMA Supported
19 —	- Reserved
18-16 MBL	Max Block Length This value indicates the maximum block size that the Host Driver can read and write to the buffer in the uSDHC. The buffer shall transfer block size without wait cycles.  000b - 512 bytes 001b - 1024 bytes 010b - 2048 bytes 011b - 4096 bytes
15-14 RETUNING_MODE	Retuning Mode This bit selects retuning method.  00b - Mode 1 01b - Mode 2 10b - Mode 3 11b - Reserved
13 USE_TUNING_SDR50	Use Tuning for SDR50 This bit is set to 1. Host controller requires tuning to operate SDR50  0b - SDR does not require tuning 1b - SDR50 requires tuning
12 —	- Reserved
11-8 TIME_COUNT_RETUNING	Time Counter for Retuning This bit indicates an initial value of the Retuning Timer for Re-Tuning Mode1 and 3. Setting to 0 disables Retuning Timer.

Table continues on the next page...

Field	Function
7-3 —	-
2 DDR50_SUPPOR T	DDR50 support This bit indicates support of DDR50 mode.
1 SDR104_SUPP ORT	SDR104 support This bit indicates support of SDR104 mode.
0 SDR50_SUPPOR T	SDR50 support This bit indicates support of SDR50 mode.

### 25.9.1.19 Watermark Level (WTMK\_LVL)

#### 25.9.1.19.1 Offset

Register	Offset
WTMK_LVL	44h

#### 25.9.1.19.2 Function

Both write and read watermark levels (FIFO threshold) are configurable. Their value can range from 1 to 128 words. Both write and read burst lengths are also configurable. Their value can range from 1 to 31 words.

#### 25.9.1.19.3 Diagram

### 25.9.1.19.4 Fields

Field	Function
31-29 —	- Reserved
28-24 WR_BRST_LEN	Write Burst Length Due to system restriction, the actual burst length may not exceed 16. The number of words the uSDHC writes in a single burst. The write burst length must be less than or equal to the write watermark level, and all bursts within a watermark level transfer will be in back-to-back mode. On reset, this field will be 8. Writing 0 to this field will result in '01000' (i.e. it is not able to clear this field).
23-16 WR_WML	Write Watermark Level The number of words used as the watermark level (FIFO threshold) in a DMA write operation. Also the number of words as a sequence of write bursts in back-to-back mode. The maximum legal value for the write watermark level is 128.
15-13 —	- Reserved
12-8 RD_BRST_LEN	Read Burst Length Due to system restriction, the actual burst length may not exceed 16. The number of words the uSDHC reads in a single burst. The read burst length must be less than or equal to the read watermark level, and all bursts within a watermark level transfer will be in back-to-back mode. On reset, this field will be 8. Writing 0 to this field will result in '01000' (i.e. it is not able to clear this field).
7-0 RD_WML	Read Watermark Level The number of words used as the watermark level (FIFO threshold) in a DMA read operation. Also the number of words as a sequence of read bursts in back-to-back mode. The maximum legal value for the read water mark level is 128.

### 25.9.1.20 Mixer Control (MIX\_CTRL)

#### 25.9.1.20.1 Offset

Register	Offset
MIX_CTRL	48h

#### 25.9.1.20.2 Function

This register is used to DMA and data transfer. To prevent data loss, The software should check if data transfer is active before writing this register. These bits are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN, and DMAEN.

**Table 25-13. Transfer Type Register Setting for Various Transfer Types**

Multi/Single Block Select	Block Count Enable	Block Count	Function
0	Don't Care	Don't Care	Single Transfer
1	0	Don't Care	Infinite Transfer
1	1	Positive Number	Multiple Transfer
1	1	Zero	No Data Transfer

28 —	- Reserved
27 —	- Reserved
26	-

Table continues on the next page...

## uSDHC Memory Map/Register Definition

Field	Function
—	Reserved
25 FBCLK_SEL	Feedback Clock Source Selection (Only used for SD3.0, SDR104 mode and EMMC HS200 mode) 0b - Feedback clock comes from the loopback CLK 1b - Feedback clock comes from the ipp_card_clk_out
24 AUTO_TUNE_EN	Auto Tuning Enable (Only used for SD3.0, SDR104 mode and and EMMC HS200 mode) 0b - Disable auto tuning 1b - Enable auto tuning
23 SMP_CLK_SEL	SMP_CLK_SEL When STD_TUNING_EN is 0, this bit is used to select Tuned clock or Fixed clock to sample data / cmd (Only used for SD3.0, SDR104 mode and EMMC HS200 mode)  0b - Fixed clock is used to sample data / cmd 1b - Tuned clock is used to sample data / cmd
22 EXE_TUNE	Execute Tuning: (Only used for SD3.0, SDR104 mode and EMMC HS200 mode) When STD_TUNING_EN is 0, this bit is set to 1 to indicate the Host Driver is starting tuning procedure. Tuning procedure is aborted by writing 0.  0b - Not Tuned or Tuning Completed 1b - Execute Tuning
21-8 —	- Reserved
7 AC23EN	Auto CMD23 Enable When this bit is set to 1, the Host Controller issues a CMD23 automatically before issuing a command specified in the Command Register.
6 NIBBLE_POS	NIBBLE_POS In DDR 4-bit mode nibble position indiction. 0- the sequence is 'odd high nibble -> even high nibble -> odd low nibble -> even low nibble'; 1- the sequence is 'odd high nibble -> odd low nibble -> even high nibble -> even low nibble'.
5 MSBSEL	Multi / Single Block Select This bit enables multiple block DATA line data transfers. For any other commands, this bit can be set to 0. If this bit is 0, it is not necessary to set the Block Count register. (Refer to <a href="#">Command Transfer Type (CMD_XFR_TYP)</a> ).  0b - Single Block 1b - Multiple Blocks
4 DTDSEL	Data Transfer Direction Select This bit defines the direction of DATA line data transfers. The bit is set to 1 by the Host Driver to transfer data from the SD card to the uSDHC and is set to 0 for all other commands.  0b - Write (Host to Card) 1b - Read (Card to Host)
3 DDR_EN	Dual Data Rate mode selection
2 AC12EN	Auto CMD12 Enable Multiple block transfers for memory require a CMD12 to stop the transaction. When this bit is set to 1, the uSDHC will issue a CMD12 automatically when the last block transfer has completed. The Host Driver shall not set this bit to issue commands that do not require CMD12 to stop a multiple block data transfer. In particular, secure commands defined in File Security Specification (see reference list) do not require CMD12. In single block transfer, the uSDHC will ignore this bit no matter it is set or not.

*Table continues on the next page...*

Field	Function
	0b - Disable 1b - Enable
1 BCEN	Block Count Enable This bit is used to enable the Block Count register, which is only relevant for multiple block transfers. When this bit is 0, the internal counter for block is disabled, which is useful in executing an infinite transfer. 0b - Disable 1b - Enable
0 DMAEN	DMA Enable This bit enables DMA functionality. If this bit is set to 1, a DMA operation shall begin when the Host Driver sets the DPSEL bit of this register. Whether the Simple DMA or the Advanced DMA is active depends on the DMA Select field of the Protocol Control register. 0b - Disable 1b - Enable

## 25.9.1.21 Force Event (FORCE\_EVENT)

### 25.9.1.21.1 Offset

Register	Offset
FORCE_EVENT	50h

### 25.9.1.21.2 Function

The Force Event Register is not a physically implemented register. Rather, it is an address at which the Interrupt Status Register can be written if the corresponding bit of the Interrupt Status Enable Register is set. This register is a write only register and writing 0 to it has no effect. Writing 1 to this register actually sets the corresponding bit of Interrupt Status Register. A read from this register always results in 0's. In order to change the corresponding status bits in the Interrupt Status Register, make sure to set IPGEN bit in System Control Register so that IPG\_CLK is always active.

Forcing a card interrupt will generate a short pulse on the DATA1 line, and the driver may treat this interrupt as a normal interrupt. The interrupt service routine may skip polling the card interrupt factor as the interrupt is self cleared.

### 25.9.1.21.3 Diagram

### 25.9.1.21.4 Fields

Field	Function
31 FEVTCINT	Force Event Card Interrupt Writing 1 to this bit generates a short low-level pulse on the internal DATA1 line, as if a self clearing interrupt was received from the external card. If enabled, the CINT bit will be set and the interrupt service routine may treat this interrupt as a normal interrupt from the external card.
30-29 —	- Reserved
28 FEVTDMAE	Force Event DMA Error Forces the DMAE bit of Interrupt Status Register to be set.
27 —	- Reserved
26 FEVTTNE	Force Tuning Error Forces the TNE bit of Interrupt Status Register to be set.

FEVTAC12EBE	Forces the AC12EBE bit in the Auto Command12 Error Status Register to be set.
2	Force Event Auto Command 12 CRC Error
FEVTAC12CE	Forces the AC12CE bit in the Auto Command12 Error Status Register to be set.
1	Force Event Auto Command 12 Time Out Error
FEVTAC12TOE	Forces the AC12TOE bit in the Auto Command12 Error Status Register to be set.
0	Force Event Auto Command 12 Not Executed
FEVTAC12NE	Forces the AC12NE bit in the Auto Command12 Error Status Register to be set.

## 25.9.1.22 ADMA Error Status Register (ADMA\_ERR\_STATUS)

### 25.9.1.22.1 Offset

Register	Offset
ADMA_ERR_STATUS	54h

### 25.9.1.22.2 Function

When an ADMA Error Interrupt has occurred, the ADMA Error States field in this register holds the ADMA state and the ADMA System Address register holds the address around the error descriptor.

For recovering from this error, the Host Driver requires the ADMA state to identify the error descriptor address as follows:

- **ST\_STOP:** Previous location set in the ADMA System Address register is the error descriptor address.
- **ST\_FDS:** Current location set in the ADMA System Address register is the error descriptor address.
- **ST\_CADR:** This state is never set because it only increments the descriptor pointer and doesn't generate an ADMA error.
- **ST\_TFR:** Previous location set in the ADMA System Address register is the error descriptor address.

In case of a write operation, the Host Driver should use the ACMD22 to get the number of the written block, rather than using this information, since unwritten data may exist in the Host Controller.

The Host Controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid=0) in the ST\_FDS state. The Host Driver can distinguish this error by reading the Valid bit of the error descriptor.

**Table 25-14. ADMA Error State Coding**

D01-D00	ADMA Error State (when error has occurred)	Contents of ADMA System Address Register
00	ST_STOP (Stop DMA)	Holds the address of the next executable Descriptor command
01	ST_FDS (Fetch Descriptor)	Holds the valid Descriptor address
10	ST_CADR (Change Address)	No ADMA Error is generated
11	ST_TFR (Transfer Data)	Holds the address of the next executable Descriptor command

### 25.9.1.22.3 Diagram

### 25.9.1.22.4 Fields

Field	Function
31-4 —	- Reserved
3 ADMADCE	ADMA Descriptor Error This error occurs when invalid descriptor fetched by ADMA.  0b - No Error 1b - Error
2 ADMALME	ADMA Length Mismatch Error This error occurs in the following 2 cases: <ul style="list-style-type: none"> <li>While the Block Count Enable is being set, the total data length specified by the Descriptor table is different from that specified by the Block Count and Block Length.</li> <li>Total data length cannot be divided by the block length.</li> </ul> 0b - No Error 1b - Error
1-0 ADMAES	ADMA Error State (when ADMA Error is occurred) This field indicates the state of the ADMA when an error has occurred during an ADMA data transfer. Refer to <a href="#">ADMA Error Status Register (ADMA_ERR_STATUS)</a> for more details.

### 25.9.1.23 ADMA System Address (ADMA\_SYS\_ADDR)

### 25.9.1.23.1 Offset

Register	Offset
ADMA_SYS_ADDR	58h

### 25.9.1.23.2 Function

This register contains the physical system memory address used for ADMA transfers.

### 25.9.1.23.3 Diagram

### 25.9.1.23.4 Fields

Field	Function
31-2 ADS_ADDR	<p>ADMA System Address</p> <p>This register holds the word address of the executing command in the Descriptor table. At the start of ADMA, the Host Driver shall set the start address of the Descriptor table. The ADMA engine increments this register address whenever fetching a Descriptor command. When the ADMA is stopped at the Block Gap, this register indicates the address of the next executable Descriptor command. When the ADMA Error Interrupt is generated, this register shall hold the valid Descriptor address depending on the ADMA state. The lower 2 bits of this register is tied to '0' so the ADMA address is always word aligned.</p> <p>Since this register supports dynamic address reflecting, when TC bit is set, it automatically alters the value of internal address counter, so SW cannot change this register when TC bit is set. Such restriction is also listed in <a href="#">Software Restrictions</a> .</p>
1-0 —	- Reserved

### 25.9.1.24 DLL (Delay Line) Control (DLL\_CTRL)

### 25.9.1.24.1 Offset

Register	Offset
DLL_CTRL	60h

### 25.9.1.24.2 Function

This register contains control bits for DLL.

### 25.9.1.24.3 Diagram

### 25.9.1.24.4 Fields

Field	Function
31-28	DLL_CTRL_REF_UPDATE_INT

Table continues on the next page...

## uSDHC Memory Map/Register Definition

Field	Function
DLL_CTRL_REF_UPDATE_INT	DLL control loop update interval. The interval cycle is $(2 + \text{REF\_UPDATE\_INT}) * \text{REF\_CLOCK}$ . By default, the DLL control loop shall update every two REF_CLOCK cycles. It should be noted that increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that may effect the delay (such as voltage and temperature)
27-20 DLL_CTRL_SLV_UPDATE_INT	DLL_CTRL_SLV_UPDATE_INT Slave delay line update interval. If default 0 is used, it means 256 cycles of REF_CLOCK. A value of 0x0f results in 15 cycles and so on. Note that software can always cause an update of the slave-delay line using the SLV_FORCE_UPDATE register. Note that the slave delay line will also update automatically when the reference DLL transitions to a locked state (from an un-locked state).
19 —	- Reserved
18-16 DLL_CTRL_SLV_DLY_TARGET1	DLL_CTRL_SLV_DLY_TARGET1 Refer to DLL_CTRL_SLV_DLY_TARGET0 below.
15-9 DLL_CTRL_SLV_OVERRIDE_VAL	DLL_CTRL_SLV_OVERRIDE_VAL When SLV_OVERRIDE = 1 This field is used to select 1 of 128 physical taps manually. A value of 0 selects tap 1, and a value of 0x7f selects tap 128.
8 DLL_CTRL_SLV_OVERRIDE	DLL_CTRL_SLV_OVERRIDE Set this bit to 1 to Enable manual override for slave delay chain using SLV_OVERRIDE_VAL; to set 0 to disable manual override. This feature does not require the DLL to be enabled using the ENABLE bit. In fact to reduce power, if SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE = 0
7 DLL_CTRL_GATE_UPDATE	DLL_CTRL_GATE_UPDATE Set this bit to 1 to prevent the DLL from updating (since when clock_in exists, glitches may appear during DLL updates). This bit may be used by software if such a condition occurs. Clear the bit to 0 to allow the DLL to update automatically.
6-3 DLL_CTRL_SLV_DLY_TARGET0	DLL_CTRL_SLV_DLY_TARGET0 The delay target for the uSDHC loopback read clock can be programmed in 1/16th increments of an ref_clock half-period. The delay is $((\{\text{DLL\_CTRL\_SLV\_DLY\_TARGET1}, \text{DLL\_CTRL\_SLV\_DLY\_TARGET0}\} + 1) * \text{REF\_CLOCK} / 2) / 16$ So the input read-clock can be delayed relative input data from $(\text{REF\_CLOCK} / 2) / 16$ to $\text{REF\_CLOCK} * 4$ .
2 DLL_CTRL_SLV_FORCE_UPD	DLL_CTRL_SLV_FORCE_UPD Setting this bit to 1, forces the slave delay line to update to the DLL calibrated value immediately. The slave delay line shall update automatically based on the SLV_UPDATE_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the slave-line update can only occur if SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered). Be sure to use it when uSDHC is idle. This function may not work when uSDHC is working on data / cmd / response.
1 DLL_CTRL_RESET	DLL_CTRL_RESET Setting this bit to 1 force a reset on DLL. This will cause the DLL to lose lock and re-calibrate to detect an REF_CLOCK half period phase shift. This signal is used by the DLL as edge-sensitive, so in order to create a subsequent reset, RESET must be taken low and then asserted again.
0 DLL_CTRL_ENABLE	DLL_CTRL_ENABLE Set this bit to 1 to enable the DLL and delay chain; otherwise; set to 0 to bypasses DLL. Note that using the slave delay line override feature with SLV_OVERRIDE and SLV_OVERRIDE_VAL, the DLL does not need to be enabled.

## 25.9.1.25 DLL Status (DLL\_STATUS)

### 25.9.1.25.1 Offset

Register	Offset
DLL_STATUS	64h

### 25.9.1.25.2 Function

This register contains the DLL status information. All bits are read only and will read the same as the power-reset value.

### 25.9.1.25.3 Diagram

### 25.9.1.25.4 Fields

Field	Function
31-16	-
—	Reserved
DLL_STS_REF_SEL	DLL_STS_REF_SEL
DLL_STS_REF_SEL	Reference delay line select taps. This is encoded by 7 bits for 127 taps.

Table continues on the next page...

<b>Field</b>	<b>Function</b>
8-2 DLL_STS_SLV_SEL	DLL_STS_SLV_SEL Slave delay line select status. This is the instant value generated from reference chain. Since the reference chain can only be updated when REF_CLOCK is detected, this value should be the right value to be updated when the reference is locked.
1 DLL_STS_REF_LOCK	DLL_STS_REF_LOCK Reference DLL lock status. This signifies that the DLL has detected and locked to a half-phase ref_clock shift, allowing the slave delay-line to perform programmed clock delays
0 DLL_STS_SLV_LOCK	DLL_STS_SLV_LOCK Slave delay-line lock status. This signifies that a valid calibration has been set to the slave-delay line and that the slave-delay line is implementing the programmed delay value

### **25.9.1.26 CLK Tuning Control and Status (CLK\_TUNE\_CTRL\_ST ATUS)**

<b>Register</b>	<b>Offset</b>
CLK_TUNE_CTRL_ST ATUS	68h

#### **25.9.1.26.2 Function**

This register contains the Clock Tuning Control status information. All bits are read only and will read the same as the power-reset value. This register is added to support SD3.0 UHS-I SDR104 mode and EMMC HS200 mode.

## 25.9.1.26.3 Diagram

## 25.9.1.26.4 Fields

Field	Function
31 PRE_ERR	PRE_ERR PRE error which means the number of delay cells added on the feedback clock is too small. It is valid only when SMP_CLK_SEL of Mix control register (bit23 of 0x48) is enabled.
30-24 TAP_SEL_PRE	TAP_SEL_PRE Reflects the number of delay cells added on the feedback clock between the feedback clock and CLK_PRE.  When AUTO_TUNE_EN (bit24 of 0x48) is disabled, TAP_SEL_PRE is always equal to DLY_CELL_SET_PRE.  When AUTO_TUNE_EN (bit24 of 0x48) is enabled, TAP_SEL_PRE will be updated automatically according to the status of the auto tuning circuit to adjust the sample clock phase.
23-20 TAP_SEL_OUT	TAP_SEL_OUT Reflect the number of delay cells added on the feedback clock between CLK_PRE and CLK_OUT.
19-16 TAP_SEL_POST T	TAP_SEL_POST Reflect the number of delay cells added on the feedback clock between CLK_OUT and CLK_POST.
15 NXT_ERR	NXT_ERR NXT error which means the number of delay cells added on the feedback clock is too large. It's valid only when SMP_CLK_SEL of Mix control register (bit23 of 0x48) is enabled.
14-8	DLY_CELL_SET_PRE

Table continues on the next page...

## uSDHC Memory Map/Register Definition

Field	Function
DLY_CELL_SE T_PRE	Set the number of delay cells on the feedback clock between the feedback clock and CLK_PRE.
7-4 DLY_CELL_SE T_OUT	DLY_CELL_SET_OUT Set the number of delay cells on the feedback clock between CLK_PRE and CLK_OUT.
3-0 DLY_CELL_SE T_POST	DLY_CELL_SET_POST Set the number of delay cells on the feedback clock between CLK_OUT and CLK_POST.

Module	Master ID
eDMA	001b
DCP	010b
All others	011b

## 26.2 Introduction

FlexSPI is a flexible SPI (Serial Peripheral Interface) host controller which supports two SPI channels and up to 4 external devices. Each channel supports Single/Dual/Quad/Octal mode data transfer (1/2/4/8 bidirectional data lines).

### 26.2.1 Features

FlexSPI block supports following features:

- Flexible sequence engine (LUT table) to support various vendor devices
  - Serial NOR Flash or other device with similar SPI protocol as Serial NOR Flash
  - Serial NAND Flash
  - HyperBus device (HyperFlash/HyperRAM)
  - FPGA device
- Flash access mode
  - Single/Dual/Quad/Octal mode
  - SDR/DDR mode
  - Individual/Parallel mode
- Support sampling clock mode:
  - Internal dummy read strobe loopbacked internally
  - Internal dummy read strobe loopbacked from pad
  - SCK clock output loopbacked from pad
  - Flash provided read strobe
- Memory mapped read/write access by AHB Bus
  - AHB RX Buffer implemented to reduce read latency. Total AHB RX Buffer size: 128 \* 64 Bits
  - 16 AHB masters supported with priority for read access
  - 8 flexible and configurable buffers in AHB RX Buffer

- AHB TX Buffer implemented to buffer all write data from one AHB burst. AHB TX Buffer size: 8 \* 64 Bits
- All AHB masters share this AHB TX Buffer. No AHB master number limitation for Write Access.
- Software triggered Flash read/write access by IP Bus
  - IP RX FIFO implemented to buffer all read data from External device. FIFO size: 16 \* 64 Bits
  - IP TX FIFO implemented to buffer all Write data to External device. FIFO size: 16 \* 64 Bits
  - DMA support to fill IP TX FIFO
  - DMA support to read IP RX FIFO
  - SCK stopped when reading flash data and IP RX FIFO is full
  - SCK stopped when writing flash data and IP TX FIFO is empty

## 26.2.2 Block diagram

The block diagram of FlexSPI is indicated in following figure:

Figure 26-1. FlexSPI block diagram

## 26.2.3 Operation Modes

This section provides information about the modes FlexSPI could be used.

- Module Disable mode

This mode is low power mode in FlexSPI module.

In module disable mode, AHB clock and serial clock domain will be gated off internally, but IPS Bus clock is not gated off. Control and status register read/write access is available except LUT/IP RX FIFO/IP TX FIFO read/write access. Serial Flash Memory access is also not available.

This mode is entered by setting MCR0[MDIS], and exited by clearing MCR0[MDIS].

- Doze mode

This mode is low power mode in SOC system.

When the system requires FlexSPI to enter doze mode and MCR0[DOZEEN] is set, the FlexSPI will wait for all transactions to complete (STS0[ARBIDLE]=0x1) and enter doze mode. In doze mode, the AHB clock and serial clock domain will be gated off internally, but IPS Bus clock is not gated off. Control and status register read/write access is available except LUT/IP RX FIFO/IP TX FIFO read/write access. Serial Flash Memory access is also not available.

This mode is entered by system request , and exited by deasserting this system request.

- Stop mode

This mode is low power mode in SOC system.

When the system requires FlexSPI to enter stop mode , FlexSPI will wait for all transactions to complete (STS0[ARBIDLE]=0x1) and return ACK handshake to system . After ACK handshake returned, the system can gate the AHB Bus clock, IPS Bus clock and serial clock in system level. There is no clock gating action internally.

This mode is entered by system stop mode request. When all command sequences finish, FlexSPI enters stop mode and returns ACK handshake. This mode is exited by deasserting system stop mode request, the ACK handshake is also deasserted immediately.

- Normal mode

In normal mode, all clocks are not gated internally. Normal register access and serial flash memory access is available.

## 26.3 Glossary for FlexSPI module

**Table 26-3. Glossary**

Term	Definition
AHB Command	AHB Command is one or several Serial Flash Memory access command sequences triggered by AHB read/write access to AHB address ranged mapped for Serial Flash Memory.
ASFM_BASE	Base address of AHB address space mapped to Serial Flash Memory.
ARDF_BASE	Base address of AHB address space mapped to IP RX FIFO.
ATDF_BASE	Base address of AHB address space mapped to IP TX FIFO.
Set	Write 1 to register bit to establish logic level one on the bit.
Clear	Write 0 to register bit to establish logic level zero on the bit.
Command Sequence	A command sequence is 4*32 bits sequence code consisting of up to 8 instructions. Command sequence should be programmed in LUT according to Flash command. When a command sequence executed, the chip selection signal becomes asserted. When a command sequence execution finished, the chip selection signal becomes negated.
DDR	Dual data transfer rate for flash access mode Flash receive data on both SCK rise and fall edge and transmit data on both SCK rise and fall edge.
Endianness	Byte Ordering scheme.
Field	Two or more register bits grouped together.
Fill	To add entries to a FIFO by software or hardware.
Instruction Code	16 bits code defining the type of command to be executed on FlexSPI interface.
IP Command	IP Command is one or several Serial Flash Memory access command sequences triggered by set register bit IPCMD.TRG.
Negated	A signal that is negated is in its inactive state. An active low signal changes from logic level 0 to logic level 1 when negated, and an active high signal changes from logic level 1 to logic level 0.
SDR	Single data transfer rate for flash access mode Flash receive data on SCK rise edge and transmit data on SCK fall edge.
Set	To set a bit or bits means to establish logic level one on the bit or bits.
SFM	Serial Flash Memory
Individual Mode	Access to a single, individual serial flash device at a time.
Parallel Mode	Read/Program Access to two serial flash devices in parallel (Port A and Port B). FlexSPI will split flash program data before transmitting to Flash or merge flash read data before putting into IP RX FIFO or AHB RX Buffer automatically.
Memory Command	Serial access Command for reading/programming/configuring. A memory command may consist one or several command sequences, for each command sequence the Chip selection signal will be asserted and deasserted once.
LUT	Look-up table to preserve command sequence. LUT is programmed by software with command sequences which is used to issue memory commands.

## 26.4 External Signal Description

This section provides the external signal information of the FlexSPI module.

**Table 26-4. External Signal List**

Signal Name	Function	Direction	Description
PCSA1	Peripheral Chip Select Flash A1	O	This signal is the chip select for the serial flash device A1.
PCSA2	Peripheral Chip Select Flash A2	O	This signal is the chip select for the serial flash device A2.
PCSB1	Peripheral Chip Select Flash B1	O	This signal is the chip select for the serial flash device B1.
PCSB2	Peripheral Chip Select Flash B2	O	This signal is the chip select for the serial flash device B2.
SCKA	Serial Clock Flash A	O	This signal is the serial clock output to the serial flash device A.
SCKB	Serial Clock Flash B	O	This signal is the serial clock output to the serial flash device B. <b>NOTE:</b> <ul style="list-style-type: none"> <li>SCKB may be optionally used as SCKA's differential clock output by setting Register Field MCR2.SCKBDIFFOPT=1'b1</li> </ul>
SCK2A	Serial Clock 2 Flash A	O	This signal is the serial clock output 2 to the serial flash device A. SCK2A is 90 degree phase shifted clocked from SCKA. Please refer to <a href="#">FlexSPI Input Timing</a> for more detail. <b>NOTE:</b> <ul style="list-style-type: none"> <li>SCK2 feature maybe dropped on SoC level. Please confirm SoC level Pin Mux for more detail.</li> </ul>
SCK2B	Serial Clock 2 Flash B	O	Similar as SCK2A.
SIOA[7:0]	Serial I/O Flash A	I/O	These signals are the data I/O lines to/from the serial flash device A.
SIOB[7:0]	Serial I/O Flash B	I/O	These signals are the data I/O lines to/from the serial flash device B.
DQSA	Data Strobe signal Flash A	I/O	Data strobe signal for port A. There are three functions for this signal: <ul style="list-style-type: none"> <li>Driven with Read Strobe by external device: Some flash devices provide the Read Strobe signal together with Read data. In this case, this pad may need a <b>pull down</b> resistor if external device drives this pad only when reading flash data.</li> <li>Driven with Latency Information by external device: Certain devices use this pin to indicate the dummy cycles needed (before Program/Read data transfer) such as HyperRAM/HyperFlash.</li> <li>Loopback dummy read strobe:</li> </ul>

Table continues on the next page...

**Table 26-4. External Signal List (continued)**

Signal Name	Function	Direction	Description
			FlexSPI controller provides internal dummy read strobe for flash read data. Higher read frequency can be achieved by looping back this dummy read strobe from pad. This pin can be floated or put some cap loads on board level to compensate SIO/SCK pins load.
DQSB	Data Strobe signal Flash B	I/O	Similar as DQSA.

## 26.5 Memory Map and register definition

This section includes the FlexSPI module memory map and detailed descriptions of all registers.

### 26.5.1 Register Access

All registers can be accessed with 8-bit, 16-bit, and 32-bit width operations. Never change the setting value of reserved fields in control registers. Changing the value of reserved fields may impact the normal functioning of the controller.

### 26.5.2 FlexSPI register descriptions

#### 26.5.2.1 FlexSPI Memory map

FlexSPI base address: 402A\_8000h

FlexSPI2 base address: 402A\_4000h

MCR0	0h

### 26.5.2.2.2 Diagram

### 26.5.2.2.3 Fields

Field	Function
31-24 AHBGRANTWAIT	<p>Timeout wait cycle for AHB command grant.</p> <p>If AHB Triggered Command is not granted by arbitrator, it will timeout after AHBGRANTTIMEOUT * 1024 AHB Clock cycles. This grant timeout may occur when the pending command sequence is IP triggered and the read/write data size is too large. When an AHB command grant time out occurs, there will be an interrupt generated (INTR[AHBCMDGE]) if this interrupt is enabled (INTEN[AHBCMDGEEN] is set) and AHB command is ignored by arbitrator.</p> <p><b>NOTE:</b> This field is for debug only, please keep default value! It is not allowed to set this field to value 0x0.</p>
23-16 IPGRANTWAIT	<p>Time out wait cycle for IP command grant.</p> <p>If IP Triggered Command is not granted by arbitrator, it will timeout after IPGRANTTIMEOUT * 1024 AHB Clock cycles. This grant timeout maybe occur when pending command sequence is AHB triggered and read/write data size is too large. When IP command grant time out occurs, there will be an interrupt generated (INTR[IPCMDGE]) if this interrupt is enabled (INTEN[IPCMDGEEN] is set 0x1) and IP command is ignored by arbitrator.</p> <p><b>NOTE:</b> This field is for debug only, please keep default value! It is not allowed to set this field to value 0x0.</p>

Table continues on the next page...

## Memory Map and register definition

Field	Function
15 —	Reserved.
14 SCKFREERUN EN	This bit is used to force SCK output free-running. For FPGA applications, external device may use SCK clock as reference clock to its internal PLL. If SCK free-running is enabled, data sampling with loopback clock from SCK pad is not supported (MCR0[RXCLKSRC]=2). 0b - Disable. 1b - Enable.
13 COMBINATION EN	This bit is to support Flash Octal mode access by combining Port A and B Data pins (SIOA[3:0] and SIOB[3:0]). <b>NOTE:</b> Combination mode is not supported if Port A and Port B are 8 bit data width. This bit should be set to zero in this case. 0b - Disable. 1b - Enable.
12 DOZEEN	Doze mode enable bit 0b - Doze mode support disabled. AHB clock and serial clock will not be gated off when there is doze mode request from system. 1b - Doze mode support enabled. AHB clock and serial clock will be gated off when there is doze mode request from system.
11 HSEN	Half Speed Serial Flash access Enable. This bit enables the divide by 2 of the clock to external serial flash devices (SCKA/SCKB) for all commands (for both SDR and DDR mode). 0b - Disable divide by 2 of serial flash clock for half speed commands. 1b - Enable divide by 2 of serial flash clock for half speed commands.
10-8 —	Reserved.
7 ATDFEN	Enable AHB bus Write Access to IP TX FIFO. 0b - IP TX FIFO should be written by IP Bus. AHB Bus write access to IP TX FIFO memory space will get bus error response. 1b - IP TX FIFO should be written by AHB Bus. IP Bus write access to IP TX FIFO memory space will be ignored but no bus error response.
6 ARDFEN	Enable AHB bus Read Access to IP RX FIFO. 0b - IP RX FIFO should be read by IP Bus. AHB Bus read access to IP RX FIFO memory space will get bus error response. 1b - IP RX FIFO should be read by AHB Bus. IP Bus read access to IP RX FIFO memory space will always return data zero but no bus error response.
5-4 RXCLKSRC	Sample Clock source selection for Flash Reading Refer <a href="#">RX Clock Source Features</a> for more details 00b - Dummy Read strobe generated by FlexSPI Controller and loopback internally. 01b - Dummy Read strobe generated by FlexSPI Controller and loopback from DQS pad. 10b - Reserved 11b - Flash provided Read strobe and input from DQS pad
3-2 —	Reserved.
1 MDIS	Module Disable When module disabled, AHB/serial clock will be gated off internally to save power. Only register access (except LUT/IP RX FIFO/IP TX FIFO) is allowed.
0 SWRESET	Software Reset This bit is auto-cleared by hardware after software reset done.

Field	Function
	Configuration registers will not be reset.

### 26.5.2.3 Module Control Register 1 (MCR1)

#### 26.5.2.3.1 Offset

Register	Offset
MCR1	4h

#### 26.5.2.3.2 Diagram

#### 26.5.2.3.3 Fields

Field	Function
31-16 SEQWAIT	Command Sequence Execution will timeout and abort after SEQWAIT * 1024 Serial Root Clock cycles. When sequence execution time out occurs, there will be an interrupt generated (INTR[SEQTIMEOUT]) if this interrupt is enabled (INTEN[SEQTIMEOUTEN] is set 0x1) and AHB command is ignored by arbitrator.  <b>NOTE:</b> It is not allowed to set this field to value 0x0.
15-0 AHBBUSWAIT	AHB Read/Write access to Serial Flash Memory space will timeout if not data received from Flash or data not transmitted after AHBBUSWAIT * 1024 ahb clock cycles, AHB Bus will get an error response. When AHB bus time out occurs, there will be an interrupt generated (INTR[AHBBUSTIMEOUT]) if this interrupt is enabled (INTR[AHBBUSTIMEOUT]) is set 0x1) and AHB command is ignored by arbitrator.  <b>NOTE:</b> It is not allowed to set this field to value 0x0.

## 26.5.2.4 Module Control Register 2 (MCR2)

### 26.5.2.4.1 Offset

Register	Offset
MCR2	8h

### 26.5.2.4.2 Diagram

### 26.5.2.4.3 Fields

Field	Function
31-24 RESUMEWAIT	Wait cycle (in AHB clock cycle) for idle state before suspended command sequence resumed.
23-20 —	Reserved.
19 SCKBDIFFOPT	SCKB pad can be used as SCKA differential clock output (inverted clock to SCKA). In this case, port B flash access is not available. After change the value of this feild, MCR0[SWRESET] should be set. 0b - SCKB pad is used as port B SCK clock output. Port B flash access is available. 1b - SCKB pad is used as port A SCK inverted clock output (Differential clock to SCKA). Port B flash access is not available.
18-17 —	Reserved.
16	Reserved.

Table continues on the next page...

Field	Function
—	
15 SAMEDEVICEEN	All external devices are same devices (both in types and size) for A1/A2/B1/B2. 0b - In Individual mode, FLSHA1CRx/FLSHA2CRx/FLSHB1CRx/FLSHB2CRx register setting will be applied to Flash A1/A2/B1/B2 seperately. In Parallel mode, FLSHA1CRx register setting will be applied to Flash A1 and B1, FLSHA2CRx register setting will be applied to Flash A2 and B2. FLSHB1CRx/FLSHB2CRx register settings will be ignored. 1b - FLSHA1CR0/FLSHA1CR1/FLSHA1CR2 register settings will be applied to Flash A1/A2/B1/B2. FLSHA2CRx/FLSHB1CRx/FLSHB2CRx will be ignored.
14 CLRLEARNPHASE	The sampling clock phase selection will be reset to phase 0 when this bit is written with 0x1. This bit will be auto-cleared immediately.
13 —	Reserved.
12 —	Reserved.
11 CLRAHBBUFOPT	This bit determines whether AHB RX Buffer and AHB TX Buffer will be cleaned automatically when FlexSPI returns STOP mode ACK. Software should set this bit if AHB RX Buffer or AHB TX Buffer will be powered off in STOP mode. Otherwise AHB read access after exiting STOP mode may hit AHB RX Buffer or AHB TX Buffer but their data entries are invalid. 0b - AHB RX/TX Buffer will not be cleaned automatically when FlexSPI return Stop mode ACK. 1b - AHB RX/TX Buffer will be cleaned automatically when FlexSPI return Stop mode ACK.
10-9 —	Reserved.
8-0 —	Reserved.

## 26.5.2.5 AHB Bus Control Register (AHBCR)

### 26.5.2.5.1 Offset

Register	Offset
AHBCR	Ch

### 26.5.2.5.2 Diagram

### 26.5.2.5.3 Fields

Field	Function
31-29 —	Reserved.
28-8 —	Reserved.
7 —	Reserved.
6 READADDROPT	AHB Read Address option bit. This option bit is intend to remove AHB burst start address alignment limitation. When FlexSPI controller is used for FPGA application, there may be requirement that FlexSPI fetches exactly the byte number as AHB burst. In this case, FPGA device should be designed as non-wordaddressable and this option bit should be set 0. 0b - There is AHB read burst start address alignment limitation when flash is accessed in parallel mode or flash is wordaddressable. 1b - There is no AHB read burst start address alignment limitation. FlexSPI will fetch more datas than AHB burst required to meet the alignment requirement.
5 PREFETCHEN	AHB Read Prefetch Enable. When AHB read prefetch is enabled, FlexSPI will fetch more flash read data than current AHB burst needed so that the read latency for next AHB read access will be reduced.
4 BUFFERABLEEN	Enable AHB bus bufferable write access support. This field affects the last beat of AHB write access, refer for more details about AHB bufferable write. 0b - Disabled. For all AHB write access (no matter bufferable or non-bufferable ), FlexSPI will return AHB Bus ready after all data is transmitted to External device and AHB command finished. 1b - Enabled. For AHB bufferable write access, FlexSPI will return AHB Bus ready when the AHB command is granted by arbitrator and will not wait for AHB command finished.
3 CACHABLEEN	Enable AHB bus cachable read access support. 0b - Disabled. When there is AHB bus cachable read access, FlexSPI will not check whether it hit AHB TX Buffer.

Table continues on the next page...

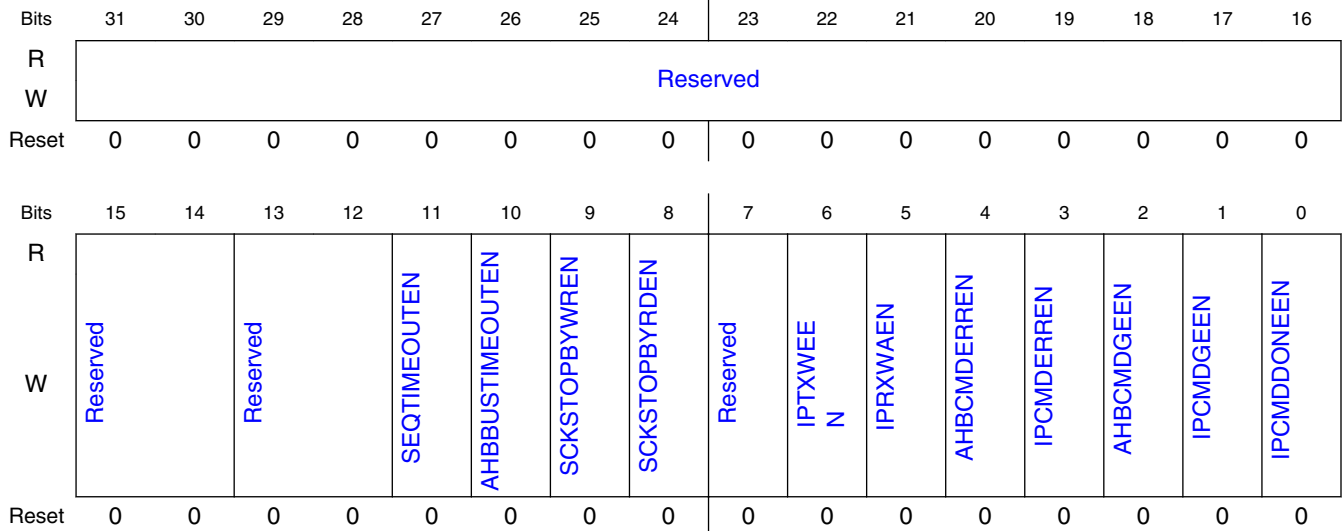

Field	Function
	1b - Enabled. When there is AHB bus cachable read access, FlexSPI will check whether it hit AHB TX Buffer first.
2-1 —	Reserved.
0 APAREN	Parallel mode enabled for AHB triggered Command (both read and write) . 0b - Flash will be accessed in Individual mode. 1b - Flash will be accessed in Parallel mode.

## 26.5.2.6 Interrupt Enable Register (INTEN)

### 26.5.2.6.1 Offset

Register	Offset
INTEN	10h

### 26.5.2.6.2 Diagram

### 26.5.2.6.3 Fields

Field	Function
31-14 —	Reserved.

Table continues on the next page...

## Memory Map and register definition

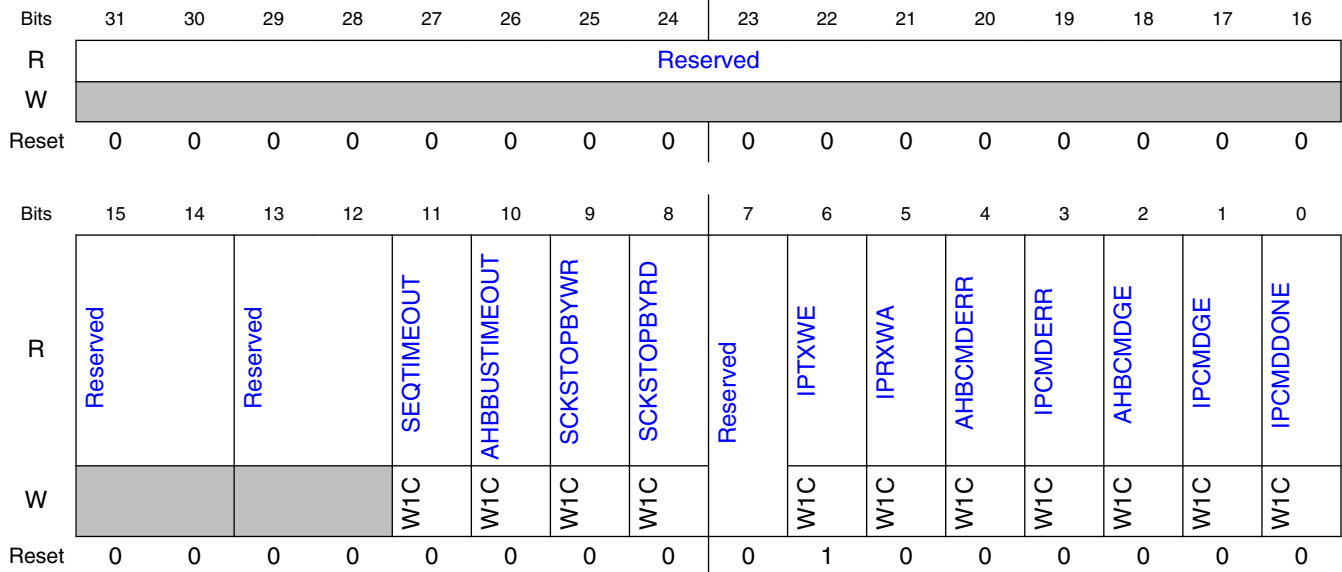

Field	Function
13-12 —	Reserved.
11 SEQTIMEOUTEN	Sequence execution timeout interrupt enable.Refer Interrupts chapter for more details.
10 AHBBUSTIMEOUTEN	AHB Bus timeout interrupt.Refer Interrupts chapter for more details.
9 SCKSTOPBYWREN	SCK is stopped during command sequence because Async TX FIFO empty interrupt enable.
8 SCKSTOPBYRDEN	SCK is stopped during command sequence because Async RX FIFO full interrupt enable.
7 —	Reserved.
6 IPTXWEEN	IP TX FIFO WaterMark empty interrupt enable. IP TX FIFO has no less empty space than WaterMark level interrupt enable.
5 IPRXWAEN	IP RX FIFO WaterMark available interrupt enable. IP RX FIFO has no less valid data than WaterMark level interrupt enable.
4 AHBCMDERREN	AHB triggered Command Sequences Error Detected interrupt enable.
3 IPCMDERREN	IP triggered Command Sequences Error Detected interrupt enable.
2 AHBCMDGEEN	AHB triggered Command Sequences Grant Timeout interrupt enable.
1 IPCMDGEEN	IP triggered Command Sequences Grant Timeout interrupt enable.
0 IPCMDDONEEN	IP triggered Command Sequences Execution finished interrupt enable.

## 26.5.2.7 Interrupt Register (INTR)

### 26.5.2.7.1 Offset

Register	Offset
INTR	14h

### 26.5.2.7.2 Diagram

### 26.5.2.7.3 Fields

Field	Function
31-14 —	Reserved.
13-12 —	Reserved.
11 SEQTIMEOUT	Sequence execution timeout interrupt.
10 AHBBUSTIMEOUT	AHB Bus timeout interrupt. Refer Interrupts chapter for more details.
9 SCKSTOPBYWR	SCK is stopped during command sequence because Async TX FIFO empty interrupt.
8 SCKSTOPBYRD	SCK is stopped during command sequence because Async RX FIFO full interrupt.
7 —	Reserved.
6 IPTXWE	IP TX FIFO watermark empty interrupt. IP TX FIFO has no less empty space than WaterMark level interrupt.
5	IP RX FIFO watermark available interrupt.

Table continues on the next page...

## Memory Map and register definition

Field	Function
IPRXWA	IP RX FIFO has no less valid data than WaterMark level interrupt.
4 AHBCMDERR	AHB triggered Command Sequences Error Detected interrupt. When an error detected for AHB command, this command will be ignored and not executed at all.
3 IPCMDERR	IP triggered Command Sequences Error Detected interrupt. When an error detected for IP command, this command will be ignored and not executed at all.
2 AHBCMDGE	AHB triggered Command Sequences Grant Timeout interrupt.
1 IPCMDGE	IP triggered Command Sequences Grant Timeout interrupt.
0 IPCMDDONE	IP triggered Command Sequences Execution finished interrupt. This interrupt is also generated when there is IPCMDGE or IPCMDERR interrupt generated.

## 26.5.2.8 LUT Key Register (LUTKEY)

### 26.5.2.8.1 Offset

Register	Offset
LUTKEY	18h

### 26.5.2.8.2 Function

The LUT Key Register contains the key to lock and unlock LUT. Refer to [Look Up Table](#) for details.

### 26.5.2.8.3 Diagram

### 26.5.2.8.4 Fields

Field	Function
31-0	The Key to lock or unlock LUT.
KEY	The key is 0x5AF05AF0. Read value is always 0x5AF05AF0.

### 26.5.2.9 LUT Control Register (LUTCR)

#### 26.5.2.9.1 Offset

Register	Offset
LUTCR	1Ch

#### 26.5.2.9.2 Function

The LUT control register is used along with LUTKEY register to lock or unlock LUT. This register has to be written immediately after writing 0x5AF05AF0 to LUTKEY register for the lock or unlock operation to be successful. Refer [Look Up Table](#) for details on locking/unlocking LUT. Setting both the LOCK and UNLOCK bits as "00" or "11" is not allowed.

#### 26.5.2.9.3 Diagram

### 26.5.2.9.4 Fields

Field	Function
31-2 —	Reserved.
1 UNLOCK	Unlock LUT
0 LOCK	Lock LUT

### 26.5.2.10 AHB RX Buffer 0 Control Register 0 (AHBRXBUF0CR0)

#### 26.5.2.10.1 Offset

Register	Offset
AHBRXBUF0CR0	20h

#### 26.5.2.10.2 Diagram

#### 26.5.2.10.3 Fields

Field	Function
31 PREFETCHEN	AHB Read Prefetch Enable for current AHB RX Buffer corresponding Master.

Table continues on the next page...

Field	Function
	The prefetch feature is disabled when AHBCR[PREFETCHEN] is set 0. This field allows prefetch disable/enable separately for each master.
30-26 —	Reserved.
25-24 PRIORITY	This priority for AHB Master Read which this AHB RX Buffer is assigned. Refer for more details.
23-20 —	Reserved.
19-16 MSTRID	This AHB RX Buffer is assigned according to AHB Master with ID (MSTR_ID). Please refer to "AHB RX Buffer Management" for AHB RX Buffer allocation.
15-8 —	Reserved.
7-0 BUFSZ	AHB RX Buffer Size in 64 bits.Refer AHB RX Buffer Management for more details.

## 26.5.2.11 AHB RX Buffer 1 Control Register 0 (AHBRXBUF1CR0)

### 26.5.2.11.1 Offset

Register	Offset
AHBRXBUF1CR0	24h

### 26.5.2.11.2 Diagram

### 26.5.2.11.3 Fields

Field	Function
31 PREFETCHEN	AHB Read Prefetch Enable for current AHB RX Buffer corresponding Master. The prefetch feature is disabled when AHBCR[PREFETCHEN] is set 0. This field allows prefetch disable/enable separately for each master.
30-26 —	Reserved.
25-24 PRIORITY	This priority for AHB Master Read which this AHB RX Buffer is assigned. Refer for more details.
23-20 —	Reserved.
19-16 MSTRID	This AHB RX Buffer is assigned according to AHB Master with ID (MSTR_ID). Please refer to "AHB RX Buffer Management" for AHB RX Buffer allocation.
15-8 —	Reserved.
7-0 BUFSZ	AHB RX Buffer Size in 64 bits.Refer AHB RX Buffer Management for more details.

### 26.5.2.12 AHB RX Buffer 2 Control Register 0 (AHBRXBUF2CR0)

#### 26.5.2.12.1 Offset

Register	Offset
AHBRXBUF2CR0	28h

#### 26.5.2.12.2 Diagram

### 26.5.2.12.3 Fields

Field	Function
31 PREFETCHEN	AHB Read Prefetch Enable for current AHB RX Buffer corresponding Master. The prefetch feature is disabled when AHBCR[PREFETCHEN] is set 0. This field allows prefetch disable/enable separately for each master.
30-26 —	Reserved.
25-24 PRIORITY	This priority for AHB Master Read which this AHB RX Buffer is assigned. Refer for more details.
23-20 —	Reserved.
19-16 MSTRID	This AHB RX Buffer is assigned according to AHB Master with ID (MSTR_ID). Please refer to "AHB RX Buffer Management" for AHB RX Buffer allocation.
15-8 —	Reserved.
7-0 BUFSZ	AHB RX Buffer Size in 64 bits.Refer AHB RX Buffer Management for more details.

### 26.5.2.13 AHB RX Buffer 3 Control Register 0 (AHBRXBUF3CR0)

#### 26.5.2.13.1 Offset

Register	Offset
AHBRXBUF3CR0	2Ch

### 26.5.2.13.2 Diagram

### 26.5.2.13.3 Fields

Field	Function
31 PREFETCHEN	AHB Read Prefetch Enable for current AHB RX Buffer corresponding Master. The prefetch feature is disabled when AHBCR[PREFETCHEN] is set 0. This field allows prefetch disable/enable separately for each master.
30-26 —	Reserved.
25-24 PRIORITY	This priority for AHB Master Read which this AHB RX Buffer is assigned. Refer for more details.
23-20 —	Reserved.
19-16 MSTRID	This AHB RX Buffer is assigned according to AHB Master with ID (MSTR_ID). Please refer to "AHB RX Buffer Management" for AHB RX Buffer allocation.
15-8 —	Reserved.
7-0 BUFSZ	AHB RX Buffer Size in 64 bits.Refer AHB RX Buffer Management for more details.

### 26.5.2.14 Flash a Control Register 0 (FLSHA1CR0 - FLSHB2CR0)

### 26.5.2.14.1 Offset

Register	Offset
FLSHA1CR0	60h
FLSHA2CR0	64h
FLSHB1CR0	68h
FLSHB2CR0	6Ch

### 26.5.2.14.2 Function

The Flash control register 0 contains Flash size setting. FlexSPI determines which device is accessed with this register setting (Chip Selection).

### 26.5.2.14.3 Diagram

### 26.5.2.14.4 Fields

Field	Function
31-23 —	Reserved.
22-0 FLSHSZ	Flash Size in KByte. The max flash size supported for each device is 4 GB. When FLSHSZ setting value is greater than 0x400000, the device flash size would be taken as 4 GB. The max total flash size supported (for all 4 devices) is also 4 GB. If the total flash size is larger than 4 GB, only 4 GB address space is accessible.

### 26.5.2.15 Flash a Control Register 1 (FLSHA1CR1 - FLSHB2CR1)

### 26.5.2.15.1 Offset

Register	Offset
FLSHA1CR1	70h
FLSHA2CR1	74h
FLSHB1CR1	78h
FLSHB2CR1	7Ch

### 26.5.2.15.2 Function

The Flash control register 1 contains the setting for FlexSPI to meet Flash device specific timings and Flash internal address space.

### 26.5.2.15.3 Diagram

### 26.5.2.15.4 Fields

Field	Function
31-16 CSINTERVAL	<p>This field is used to set the minimum interval between flash device Chip selection deassertion and flash device Chip selection assertion. If external flash has a limitation on the interval between command sequences, this field should be set accordingly. If there is no limitation, set this field with value 0x0.</p> <p>When CSINTERVALUNIT is 0x0, the chip selection invalid interval is: CSINTERVAL * 1 serial clock cycle; When CSINTERVALUNIT is 0x1, the chip selection invalid interval is: CSINTERVAL * 256 serial clock cycle.</p> <p><b>NOTE:</b> The chip selection interval is 2 cycle at least even if CSINTERVAL is less than 2.</p>
15	<p>CS interval unit</p> <p>0b - The CS interval unit is 1 serial clock cycle</p>

Table continues on the next page...

Field	Function
CSINTERVALUNIT	1b - The CS interval unit is 256 serial clock cycle
14-11 CAS	Column Address Size. When external flash has separate address field for row address and column address, this field should be set to flash column address bit width. FlexSPI will automatically split flash mapped address to Row address and Column address according to CAS field and WA field setting. This bit should be set to 0x0 when external Flash don't support column address. FlexSPI will transmit all flash address bits as Row address. For flash address mapping, please refer to <a href="#">Flash memory map</a> for more detail.
10 WA	Word Addressable. This bit should be set when external Flash is word addressable. If Flash is word addressable, it should be access in terms of 16 bits. At this time, FlexSPI will not transmit Flash address bit 0 to external Flash. For flash address mapping, please refer to <a href="#">Flash memory map</a> for more detail.
9-5 TCSH	Serial Flash CS Hold time. This field is used to meet flash TCSH timing requirement. Serial flash CS Hold time promised by FlexSPI is: TCSH in serial root clock cycles (for both SDR and DDR mode). Please refer to <a href="#">FlexSPI Input Timing</a> for more detail.
4-0 TCSS	Serial Flash CS setup time. This field is used to meet flash TCSS timing requirement. Serial flash CS Setup time promised by FlexSPI is: (TCSS + 1/2) serial root clock cycles (for both SDR and DDR mode). Please refer to <a href="#">FlexSPI Input Timing</a> for more detail.

## 26.5.2.16 Flash a Control Register 2 (FLSHA1CR2 - FLSHB2CR2)

### 26.5.2.16.1 Offset

Register	Offset
FLSHA1CR2	80h
FLSHA2CR2	84h
FLSHB1CR2	88h
FLSHB2CR2	8Ch

### 26.5.2.16.2 Function

Flash Control Register 2 contains setting field for AHB Bus access configuration. If the 4 external device are in different types, AHB read/write command may use different command sequences and AHB bus ready wait time may be also different.

### 26.5.2.16.3 Diagram

### 26.5.2.16.4 Fields

Field	Function
31 CLRINSTRPTR	Clear the instruction pointer which is internally saved pointer by JMP_ON_CS. Refer Programmable Sequence Engine for details. This field is used for AHB Read access to external Flash supporting XIP (Execute-In-Place) mode.
30-28 AWRWAITUNIT	AWRWAIT unit 000b - The AWRWAIT unit is 2 ahb clock cycle 001b - The AWRWAIT unit is 8 ahb clock cycle 010b - The AWRWAIT unit is 32 ahb clock cycle 011b - The AWRWAIT unit is 128 ahb clock cycle 100b - The AWRWAIT unit is 512 ahb clock cycle 101b - The AWRWAIT unit is 2048 ahb clock cycle 110b - The AWRWAIT unit is 8192 ahb clock cycle 111b - The AWRWAIT unit is 32768 ahb clock cycle
27-16 AWRWAIT	For certain devices (such as FPGA), it need some time to write data into internal memory after the command sequences finished on FlexSPI interface. If another Read command sequence comes before previous programming finished internally, the read data may be wrong. This field is used to hold AHB Bus ready for AHB write access to wait the programming finished in external device. Then there will be no AHB read command triggered before the programming finished in external device. The Wait cycle between AHB triggered command sequences finished on FlexSPI interface and AHB return Bus ready: AWRWAIT * AWRWAITUNIT
15-13 AWRSEQNUM	Sequence Number for AHB Write triggered Command. For certain flash devies (E.g HyperFlash/HyperRam/Serial NAND flash), a Flash programming access is done by several command sequences. AHB write Command will trigger (AWRSEQNUM+1) command sequences to external flash every time. FlexSPI execute the sequences in LUT incremently.

Table continues on the next page...

Field	Function
	<b>NOTE:</b> <ul style="list-style-type: none"> <li>• Software should make sure the last sequence index never exceed LUT sequence numbers: <math>AWRSEQID+AWRSEQNUM &lt; 16</math></li> <li>• Software need to make sure field AWRSEQNUM and LUT is configured correctly according to external device spec. FlexSPI don't check the sequence and just execute them one by one.</li> </ul>
12 —	Reserved.
11-8 AWRSEQID	Sequence Index for AHB Write triggered Command.
7-5 ARDSEQNUM	Sequence Number for AHB Read triggered Command in LUT. For certain flash devies (E.g HyperFlash/HyperRam/Serial NAND flash), a Flash reading access is done by several command sequences. AHB read Command will trigger (ARDSEQNUM+1) command sequences to external flash every time. FlexSPI execute the sequences in LUT incremently. <b>NOTE:</b> <ul style="list-style-type: none"> <li>• Software should make sure the last sequence index never exceed LUT sequence numbers: <math>ARDSEQID+ARDSEQNUM \leq 16</math></li> <li>• Software need to make sure field ARDSEQNUM and LUT is configured correctly according to external device spec. FlexSPI don't check the sequence and just execute them one by one.</li> </ul>
4 —	Reserved.
3-0 ARDSEQID	Sequence Index for AHB Read triggered Command in LUT.

## 26.5.2.17 Flash Control Register 4 (FLSHCR4)

### 26.5.2.17.1 Offset

Register	Offset
FLSHCR4	94h

### 26.5.2.17.2 Function

The flash control register 4 provide the configuration for all external devices.

### 26.5.2.17.3 Diagram

### 26.5.2.17.4 Fields

Field	Function
31-5 —	Reserved.
4 —	Reserved.
3 WMENB	Write mask enable bit for flash device on port B. When write mask function is needed for memory device on port B, this bit must be set. 0b - Write mask is disabled, DQS(RWDS) pin will be un-driven when writing to external device. 1b - Write mask is enabled, DQS(RWDS) pin will be driven by FlexSPI as write mask output when writing to external device.
2 WMENA	Write mask enable bit for flash device on port A. When write mask function is needed for memory device on port A, this bit must be set. 0b - Write mask is disabled, DQS(RWDS) pin will be un-driven when writing to external device. 1b - Write mask is enabled, DQS(RWDS) pin will be driven by FlexSPI as write mask output when writing to external device.
1 —	Reserved.
0 WMOPT1	Write mask option bit 1. This option bit could be used to remove AHB write burst start address alignment limitation. 0b - DQS pin will be used as Write Mask when writing to external device. There is no limitation on AHB write burst start address alignment when flash is accessed in individual mode. 1b - DQS pin will not be used as Write Mask when writing to external device. There is limitation on AHB write burst start address alignment when flash is accessed in individual mode.

### 26.5.2.18 IP Control Register 0 (IPCR0)

### 26.5.2.18.1 Offset

Register	Offset
IPCR0	A0h

### 26.5.2.18.2 Function

The IP control registers provide all the configuration required for IP commands. This register provides the flash start address to be accessed for IP command. FlexSPI will determine the chip select automatically according to this start address.

#### NOTE

- It's not allowed to issue IP command crossing Flash device boundaries. Otherwise there will be IPCMDERR interrupt generated.
- This register should be set before IP command triggered.
- This register setting should not be changed while an IP command is in progress.

### 26.5.2.18.3 Diagram

### 26.5.2.18.4 Fields

Field	Function
31-0 SFAR	Serial Flash Address for IP command.

## 26.5.2.19 IP Control Register 1 (IPCR1)

### 26.5.2.19.1 Offset

Register	Offset
IPCR1	A4h

### 26.5.2.19.2 Function

The IP control registers provide all the configuration required for IP command. This register provides the flash read/program data size, sequence index in LUT, sequence number and individual/parallel mode setting for IP command.

#### NOTE

- This register should be before IP command triggered.
- This register setting should not be changed before IP command finished.

### 26.5.2.19.3 Diagram

### 26.5.2.19.4 Fields

Field	Function
31 IPAREN	Parallel mode Enabled for IP command. 0b - Flash will be accessed in Individual mode. 1b - Flash will be accessed in Parallel mode.
30-27 —	Reserved.
26-24	Sequence Number for IP command: ISEQNUM+1.

*Table continues on the next page...*

Field	Function
ISEQNUM	
23-20 —	Reserved.
19-16 ISEQID	Sequence Index in LUT for IP command.
15-0 IDATSZ	Flash Read/Program Data Size (in Bytes) for IP command.

## 26.5.2.20 IP Command Register (IPCMD)

### 26.5.2.20.1 Offset

Register	Offset
IPCMD	B0h

### 26.5.2.20.2 Function

This register is used to trigger a IP command to access external flash device. IP command will be executed on FlexSPI interface after granted by arbitrator.

### 26.5.2.20.3 Diagram

### 26.5.2.20.4 Fields

Field	Function
31-1	Reserved.

Table continues on the next page...

## Memory Map and register definition

Field	Function
—	
0 TRG	Setting this bit will trigger an IP Command. <b>NOTE:</b> <ul style="list-style-type: none"> <li>It's not allowed to trigger another IP command before previous IP command is finished on FlexSPI interface. Software need to poll register bit <a href="#">INTR_IP_CMD_DONE</a> or wait for this interrupt in order to wait for IP command finished.</li> </ul>

## 26.5.2.21 IP RX FIFO Control Register (IPRXFCR)

### 26.5.2.21.1 Offset

Register	Offset
IPRXFCR	B8h

### 26.5.2.21.2 Function

This register provides the configuration fields for IP RX FIFO management.

### 26.5.2.21.3 Diagram

### 26.5.2.21.4 Fields

Field	Function
31-6 —	Reserved.
5-2	Watermark level is (RXWMRK+1)*64 Bits.

*Table continues on the next page...*

Field	Function
RXWMRK	Interrupt register bit IPRXWA is set when filling level in IP RX FIFO is no less than Watermark level by FlexSPI. There will be a DMA request when the filling level is no less than Watermark level and DMA read is enabled (register bit <b>RXDMAEN</b> is set). There will be an IPRXWA (IP RX FIFO watermark available) interrupt generated when the filling level is no less than Watermark level and IPRXWA interrupt is enabled (register bit <b>INTEN_IPRXWA</b> is set).  <b>NOTE:</b> After write-1-clear to INTR[IPRXWA], read address should be rolled back to start address (memory mapped).If IP RX FIFO is read by IP bus, the read address to IP RX FIFO should roll back to RFDR0;If IP RX FIFO is read by AHB bus, the read address to IP RX FIFO should roll back to ARDF_BASE.
1 RXDMAEN	IP RX FIFO reading by DMA enabled. 0b - IP RX FIFO would be read by processor. 1b - IP RX FIFO would be read by DMA.
0 CLRIPRXF	Clear all valid data entries in IP RX FIFO. The read/write pointers in IP RX FIFO will be reset.

## 26.5.2.22 IP TX FIFO Control Register (IPTXFCR)

### 26.5.2.22.1 Offset

Register	Offset
IPTXFCR	BCh

### 26.5.2.22.2 Function

This register provides the configuration fields for IP TX FIFO management.

### 26.5.2.22.3 Diagram

### 26.5.2.22.4 Fields

Field	Function
31-6 —	Reserved.
5-2 TXWMRK	<p>Watermark level is <math>(TXWMRK+1)*64</math> Bits.</p> <p>Interrupt register bit IPTXWE is set when empty level in IP TX FIFO is no less than Watermark level by FlexSPI. There will be a DMA request when empty level is no less than Watermark level and DMA filling is enable (register bit <b>TXDMAEN</b> is set). There will be an IPTXWE (IP TX FIFO Watermark Empty) interrupt generated when empty level is no less than Watermark level and IPTXWE interrupt is enable (register bit <b>INTEN_IPTXWE</b> is set).</p> <p><b>NOTE:</b></p> <ul style="list-style-type: none"> <li>• The watermark level should be no more than the write window.</li> <li>• The watermark level should be no more than IP TX FIFO size.</li> <li>• The write address to IP RX FIFO should roll back to the start address of write window after pushing IP TX FIFO by writing-one-clear to INTR[IPTXWE].</li> </ul>
1 TXDMAEN	<p>IP TX FIFO filling by DMA enabled.</p> <p>0b - IP TX FIFO would be filled by processor. 1b - IP TX FIFO would be filled by DMA.</p>
0 CLRIPTXF	<p>Clear all valid data entries in IP TX FIFO.</p> <p>The read/write pointers in IP TX FIFO will be reset.</p>

### 26.5.2.23 DLL Control Register 0 (DLLACR - DLLBCR)

#### 26.5.2.23.1 Offset

Register	Offset
DLLACR	C0h
DLLBCR	C4h

#### 26.5.2.23.2 Function

This register provides the configuration fields for Flash A/B sample clock DLL.

### 26.5.2.23.3 Diagram

### 26.5.2.23.4 Fields

Field	Function
31-15 —	Reserved.
14-9 OVRDVAL	Slave clock delay line delay cell number selection override value. When OVRDEN is set 0x1, the delay cell number in DLL is OVRDVAL+1.
8 OVRDEN	Slave clock delay line delay cell number selection override enable.
7 —	Reserved.
6-3 SLVDLYTARGET	The delay target for slave delay line is: $((\text{SLVDLYTARGET}+1) * 1/32 * \text{clock cycle of reference clock (serial clock)})$ .
2 —	Reserved.
1 DLLRESET	Software could force a reset on DLL by setting this field to 0x1. This will cause the DLL to lose lock and re-calibrate to detect an ref_clock half period phase shift. The reset action is edge triggered, so software need to clear this bit after set this bit (no delay limitation).
0 DLLLEN	DLL calibration enable. When this bit is cleared, DLL calibration is disabled and the delay cell number in slave delay line is always 1. Please note that SLV delay line is overridden when OVRDEN bit is set and this bit field setting is ignored.

## 26.5.2.24 Status Register 0 (STS0)

### 26.5.2.24.1 Offset

Register	Offset
STS0	E0h

### 26.5.2.24.2 Diagram

### 26.5.2.24.3 Fields

Field	Function
31-12 —	Reserved.
11-8 —	Reserved.
7-4 —	Reserved.
3-2 ARBCMDSRC	This status field indicates the trigger source of current command sequence granted by arbitrator. This field value is meaningless when ARB_CTL is not busy (STS0[ARBIDLE]=0x1). 00b - Triggered by AHB read command (triggered by AHB read). 01b - Triggered by AHB write command (triggered by AHB Write). 10b - Triggered by IP command (triggered by setting register bit IPCMD.TRG). 11b - Triggered by suspended command (resumed).
1 ARBIDLE	This status bit indicates the state machine in ARB_CTL is busy and there is command sequence granted by arbitrator and not finished yet on FlexSPI interface. When ARB_CTL state (ARBIDLE=0x1) is idle, there will be no transaction on FlexSPI interface also (SEQIDLE=0x1). So this bit should be polled to wait for FlexSPI controller become idle instead of SEQIDLE.

Table continues on the next page...

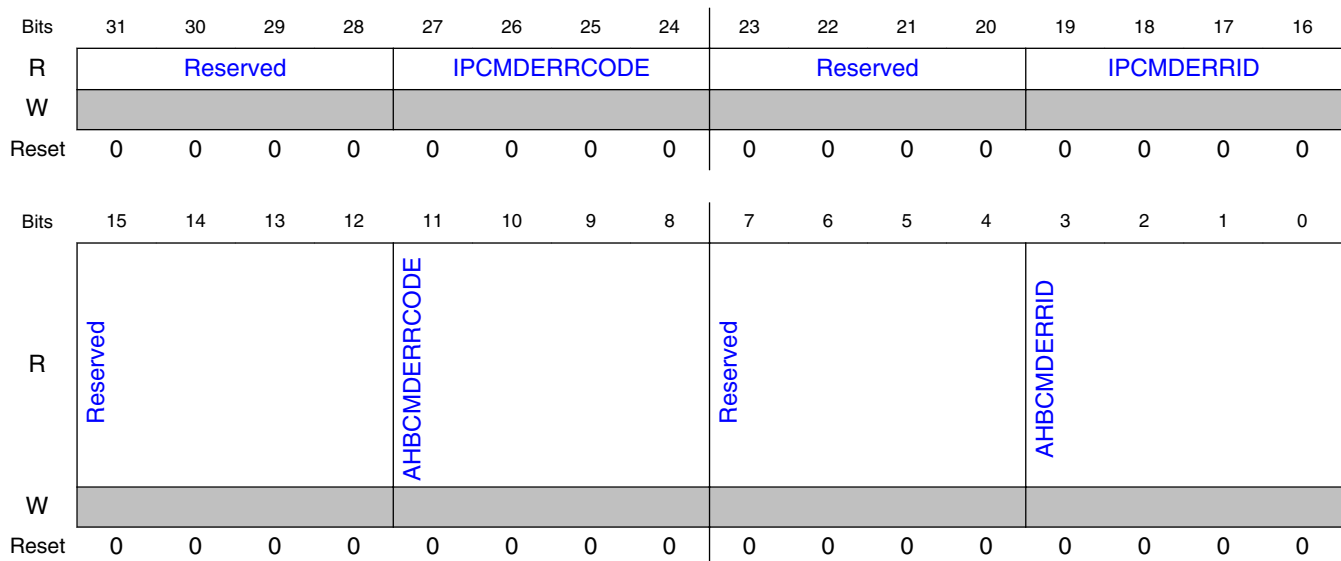

Field	Function
0 SEQIDLE	This status bit indicates the state machine in SEQ_CTL is idle and there is command sequence executing on FlexSPI interface.

## 26.5.2.25 Status Register 1 (STS1)

### 26.5.2.25.1 Offset

Register	Offset
STS1	E4h

### 26.5.2.25.2 Diagram

### 26.5.2.25.3 Fields

Field	Function
31-28 —	Reserved.
27-24 IPCMDERRCODE	Indicates the Error Code when IP command Error detected. This field will be cleared when INTR[IPCMDERR] is write-1-clear(w1c). 0000b - No error. 0010b - IP command with JMP_ON_CS instruction used in the sequence.

Table continues on the next page...

## Memory Map and register definition

Field	Function
	0011b - There is unknown instruction opcode in the sequence. 0100b - Instruction DUMMY_SDR/DUMMY_RWDS_SDR used in DDR sequence. 0101b - Instruction DUMMY_DDR/DUMMY_RWDS_DDR used in SDR sequence. 0110b - Flash access start address exceed the whole flash address range (A1/A2/B1/B2). 1110b - Sequence execution timeout. 1111b - Flash boundary crossed.
23-20 —	Reserved.
19-16 IPCMDERRID	Indicates the sequence Index when IP command error detected. This field will be cleared when INTR[IPCMDERR] is write-1-clear(w1c).
15-12 —	Reserved.
11-8 AHBCMDERRC ODE	Indicates the Error Code when AHB command Error detected. This field will be cleared when INTR[AHBCMDERR] is write-1-clear(w1c). 0000b - No error. 0010b - AHB Write command with JMP_ON_CS instruction used in the sequence. 0011b - There is unknown instruction opcode in the sequence. 0100b - Instruction DUMMY_SDR/DUMMY_RWDS_SDR used in DDR sequence. 0101b - Instruction DUMMY_DDR/DUMMY_RWDS_DDR used in SDR sequence. 1110b - Sequence execution timeout.
7-4 —	Reserved.
3-0 AHBCMDERRID	Indicates the sequence index when an AHB command error is detected. This field will be cleared when INTR[AHBCMDERR] is write-1-clear(w1c).

## 26.5.2.26 Status Register 2 (STS2)

### 26.5.2.26.1 Offset

Register	Offset
STS2	E8h

### 26.5.2.26.2 Function

This register indicates the status of Flash A and B sample clock DLLs.

### 26.5.2.26.3 Diagram

### 26.5.2.26.4 Fields

Field	Function
31-30 —	Reserved.
29-24 BREFSEL	Flash B sample clock reference delay line delay cell number selection.
23-18 BSLVSEL	Flash B sample clock slave delay line delay cell number selection.
17 BREFLOCK	Flash B sample clock reference delay line locked.
16 BSLVLOCK	Flash B sample clock slave delay line locked.
15-14 —	Reserved.
13-8 AREFSEL	Flash A sample clock reference delay line delay cell number selection.
7-2 ASLVSEL	Flash A sample clock slave delay line delay cell number selection .
1 AREFLOCK	Flash A sample clock reference delay line locked.
0 ASLVLOCK	Flash A sample clock slave delay line locked.

## 26.5.2.27 AHB Suspend Status Register (AHBSPNDSTS)

### 26.5.2.27.1 Offset

Register	Offset
AHBSPNDSTS	ECh

### 26.5.2.27.2 Function

Indicates the status of Suspended AHB Read Prefetch command sequence. When there is IP/AHB command triggered and arbitrator is processing an AHB Read sequence (prefetching more data not for current AHB burst), the prefetch sequence will be suspended and may be resumed when there is no transaction on FlexSPI any more. FlexSPI saves only one AHB prefetch sequence. When a new prefetch sequence is suspended with an active sequence suspended already, previous suspended sequence will be removed and never resumed. Refer [Command Abort and Suspend](#) for more details.

### 26.5.2.27.3 Diagram

### 26.5.2.27.4 Fields

Field	Function
31-16 DATLFT	Left Data size for suspended command sequence (in byte).
15-4	Reserved.

Table continues on the next page...

Field	Function
—	
3-1 BUFID	AHB RX BUF ID for suspended command sequence.
0 ACTIVE	Indicates if an AHB read prefetch command sequence has been suspended.

## 26.5.2.28 IP RX FIFO Status Register (IPRXFSTS)

### 26.5.2.28.1 Offset

Register	Offset
IPRXFSTS	F0h

### 26.5.2.28.2 Function

This status register indicates the status of IP RX FIFO.

### 26.5.2.28.3 Diagram

### 26.5.2.28.4 Fields

Field	Function
31-16 RDCNTR	Total Read Data Counter: RDCNTR * 64 Bits.
15-8 —	Reserved.

Table continues on the next page...

**Memory Map and register definition**

Field	Function
7-0	Fill level of IP RX FIFO.
FILL	Valid Data entries in IP RX FIFO is: FILL * 64 Bits.

### 26.5.2.29 IP TX FIFO Status Register (IPTXFSTS)

#### 26.5.2.29.1 Offset

Register	Offset
IPTXFSTS	F4h

#### 26.5.2.29.2 Function

This status register indicates the status of IP TX FIFO.

#### 26.5.2.29.3 Diagram

#### 26.5.2.29.4 Fields

Field	Function
31-16 WRCNTR	Total Write Data Counter: WRCNTR * 64 Bits.
15-8 —	Reserved.
7-0 FILL	Fill level of IP TX FIFO. Valid Data entries in IP TX FIFO is: FILL * 64 Bits.

### 26.5.2.30 IP RX FIFO Data Register a (RFDR0 - RFDR31)

#### 26.5.2.30.1 Offset

For a = 0 to 31:

Register	Offset
RFDRa	100h + (a × 4h)

#### 26.5.2.30.2 Function

These registers provide read access to IP RX FIFO by IPS bus. The read value is unknown for read access to invalid entries in IP RX FIFO.

#### 26.5.2.30.3 Diagram

#### 26.5.2.30.4 Fields

Field	Function
31-0 RXDATA	RX Data

### 26.5.2.31 IP TX FIFO Data Register a (TFDR0 - TFDR31)

### 26.5.2.31.1 Offset

For a = 0 to 31:

Register	Offset
TFDRa	180h + (a × 4h)

### 26.5.2.31.2 Function

These registers provide write access to IP TX FIFO by IPS bus.

### 26.5.2.31.3 Diagram

### 26.5.2.31.4 Fields

Field	Function
31-0 TXDATA	TX Data

## 26.5.2.32 LUT a (LUT0 - LUT63)

### 26.5.2.32.1 Offset

For a = 0 to 63:

Register	Offset
LUTa	200h + (a × 4h)

### 26.5.2.32.2 Function

The LUT is a look-up-table for command sequences. Software should set the sequence index before triggering an IP command or AHB command. FlexSPI will fetch the command sequence from LUT when IP/AHB command triggered. There are 16 command sequences in LUT. Refer [Look Up Table](#) for more details.

#### NOTE

LUT is implemented as memory, so the reset value is unknown.

### 26.5.2.32.3 Diagram

### 26.5.2.32.4 Fields

Field	Function
31-26 OPCODE1	OPCODE1
25-24 NUM_PADS1	NUM_PADS1
23-16 OPERAND1	OPERAND1
15-10 OPCODE0	OPCODE
9-8 NUM_PADS0	NUM_PADS0
7-0 OPERAND0	OPERAND0

Field	Function
OPERAND0	

## 26.6 AHB Memory Map definition

This section describes FlexSPI module AHB memory map in detail.

### 26.6.1 AHB Memory Map for Serial Flash memory access

Following address range is mapped for AHB read/write access to serial flash memory: 0x60000000 - 0x80000000.

AHB Bus feature supported for Serial Flash memory reading:

- Cachable and Non-Cachable access
- Prefetch Enable/Disable
- Burst size: 8/16/32/64 bits
- All burst type: SINGLE/INCR/WRAP4/INCR4/WRAP8/INCR8/WRAP16/INCR16

AHB Bus feature for Serial Flash memory writing:

- Bufferable and Non-Bufferable access
- Burst size: 8/16/32/64 bits
- All burst type: SINGLE/INCR/WRAP4/INCR4/WRAP8/INCR8/WRAP16/INCR16

Refer [Flash access by AHB Command](#) for more details about AHB access to Serial Flash memory.

### 26.6.2 AHB Memory Map for IP RX FIFO read access

Following address range is mapped for AHB read access to IP RX FIFO: 0x7FC00000 - 0x7FC00080.

AHB Bus feature supported for IP RX FIFO reading:

- Burst size: 8/16/32/64 bits
- All burst type: SINGLE/INCR/WRAP4/INCR4/WRAP8/INCR8/WRAP16/INCR16

Refer [Reading Data from IP RX FIFO](#) for more details about IP RX FIFO reading.

### 26.6.3 AHB Memory Map for IP TX FIFO write access

Following address range is mapped for AHB write access to IP TX FIFO: 0x7F800000 - 0x7F800080.

AHB Bus feature supported for IP TX FIFO writing:

- Burst size: 8/16/32/64 bits
- All burst type: SINGLE/INCR/WRAP4/INCR4/WRAP8/INCR8/WRAP16/INCR16

Refer [Filling Data to IP TX FIFO](#) for more details about IP TX FIFO filling.

## 26.7 Functional description

The following sections describe functional details of the FlexSPI module.

### 26.7.1 Clocks

This section describes clocks and special clocking requirements of the FlexSPI module.

**Table 26-5. Clock Usage**

Clock Name	Description	Comment
serial clock root (ipg_clk_sfck)	Root clock for Serial domain	-
ahb clock (HCLK)	AHB Bus clock	-
ipg clock (ipg_clk)	IPS Bus clock	-
SCK	Output clock on SCK pin	Half clock frequency of serial clock root in DDR mode, and same frequency as serial clock root in SDR mode. Clock output toggles during the whole flash access sequence.
SCK2	Output clock on SCK2 pin	90 degree phase shifted from SCK in DDR mode. No clock output in SDR mode (Clock gated).
DQS_OUT	Dummy Read Strobe output	Same frequency as SCK. Clock output toggles during READ/LEARN instructions.
DQS_IN	Sample clock for RX Data	Same frequency as SCK. Sample clock comes from loopbacked dummy read strobe, loopbacked SCK or Flash provided read strobe.

## 26.7.2 Interrupts

This section describes all the interrupts that the FlexSPI module generates.

- **IP command done interrupt**

When IP command is finished, there will be interrupt generated if INTEN[IPCMDDONEEN] is set to 0x1.

- **IP command grant error interrupt**

When IP command grant timeout (not grant after MCR0[IPGRANTWAIT] \* 1024 ahb clock cycles), there will be interrupt generated if INTEN[IPCMDGEEEN] is set to 0x1.

- **AHB command grant error interrupt**

When AHB command grant timeout (not grant after MCR0[AHBGRANTWAIT] \* 1024 ahb clock cycles), there will be interrupt generated if INTEN[AHBCMDGEEEN] is set to 0x1.

- **IP command error interrupt**

When there is command check error or command execution error for IP command, there will be interrupt generated if INTEN[IPCMDERREN] is set to 0x1. Refer [Overview of Error Flags](#) for more details.

- **AHB command error interrupt**

When there is command check error or command execution error for AHB command, there will be interrupt generated if INTEN[AHBCMDERREN] is set to 0x1. Refer [Overview of Error Flags](#) for more details.

- **IP RX FIFO watermark available interrupt**

When the fill level of IP RX FIFO is no less than watermark level (IPRXFCR[RXWMRK]), there will be interrupt generated if INTEN[IPRXWAEN] is set to 0x1.

- **IP TX FIFO watermark exceed interrupt**

When the empty level of IP TX FIFO is no less than watermark level (IPTXFCR[TXWMRK]), there will be interrupt generated if INTEN[IPRXWAEN] is set to 0x1.

- **Sequence execution timeout interrupt**

When a sequence execution time exceeds the timeout wait time (MCR1[SEQWAIT]), an interrupt will be generated if INTEN[SEQTIMEOUTEN] is set to 0x1. For example, the following Flash read command sequence will last about 8000000 cycle (in serial root clock). If SEQWAIT is set 0xFFFF, there will be sequence timeout interrupt generated.

- Triggered by IP command
- Flash read data size is 0x1000000 bytes
- Flash accessed in Single mode and SDR mode,
- **AHB Bus timeout interrupt**

When AHB bus response timeout, there will be interrupt generated if INTEN[AHBBUSTIMEOUTEN] is set to 0x1. A typical case is AHB read sequence is not configured properly in LUT (such as without READ instruction). There will never be data read from external device, then FlexSPI will never hit the read data in AHB RX Buffers for AHB Read command.

- **SCK stopped by write command interrupt**

When IP TX FIFO is empty during write command sequence execution, FlexSPI will stop SCK output clock toggling and wait for write data filling. At this time, this interrupt is generated if enabled by INTEN register.

- **SCK stopped by read command interrupt**

When IP RX FIFO is full during read command sequence execution, FlexSPI will stop SCK output clock toggling and wait for read data read out from IP RX FIFO. At this time, this interrupt is generated if enabled by INTEN register.

### 26.7.3 Flash Connection

There are two Octal SPI interface ports (A port and B port), both of them support octal Flash operation. Each port supports 2 flash devices by providing 2 chip select outputs. So FlexSPI support 4 device at most.

The connection diagram with 4 devices is as following:

**Figure 26-2. Flash connection diagram with four devices**

#### NOTE

- Flash A1 and A2 could be two flash chip package or two flash die on the same package. There is no difference to FlexSPI. Same for Flash B1 and B2
- Flash A1 and B1 could be accessed parallelly in parallel mode. FlexSPI will merge/split the flash read/program data automatically. Same for A2 and B2.
- In parallel mode, A1 and A2 could not be accessed at the same time. Same for B1 and B2.
- In individual mode, A1, A2, B1 and B2 could not be accessed at the same time. But these four device could be accessed seperately.

There is a combination mode to provide octal flash support by combining A port (SIOA[3:0]) and B port (SIOB[3:0]) together. The connection diagram for this combination mode is as following:

Figure 26-3. Flash connection diagram with combination mode

## 26.7.4 Flash Access mode

This section describes flash access mode.

### 26.7.4.1 SPI clock mode

FlexSPI support only SPI clock mode 0: Clock polarity (CPOL)=0 and Clock Phase (CPHA)=0. SCK will stay at logic low state when SPI bus is idle.

### 26.7.4.2 Flash Individual mode and Parallel mode

In individual mode, Flash read/write data is received/transmit on port A or port B.

In parallel mode, Flash read/write data is received/transmit on port A and B port parallelly. FlexSPI will merge/split the flash read/program data automatically. Please note that only read/program data is merged/split (READ/WRITE instruction). For other instructions (such as Command/Address/Mode/Data size), same command code/address/mode bits/data size information will be transmit to port A and port B device. For more detail, please refer to [Instruction execution on SPI interface](#).

Individual mode and parallel mode is determined statically by register field IPCR1[IPAREN] (for IP command) or AHBCR[APAREN] (for AHB command).

### **26.7.4.3 SDR mode and DDR mode**

In SDR (Single Data transfer Rate) mode, Flash receives data on SCK rise edge and transmit data on SCK fall edge..

In DDR (Dual Data transfer Rate) mode, Flash receives data on both SCK rise and fall edges and transmit data on both SCK rise and fall edges.

SDR and DDR mode is determined by instruction (opcode) in LUT sequence dynamically. There is no static configuration register field setting for SDR and DDR mode. For more details about input and output timing, refer [FlexSPI Input Timing](#) and [FlexSPI Output Timing](#).

### **26.7.4.4 Single, Dual, Quad, Octal mode**

In Single mode, flash transmit/receive data on 1 Data pin (SIO0 for transmitting, SIO1 for receiving).

In Dual mode, flash transmit/receive data on 2 Data pin (SIO0~SIO1 for both transmitting and receiving).

In Quad mode, flash transmit/receive data on 4 Data pin (SIO0~SIO3 for both transmitting and receiving).

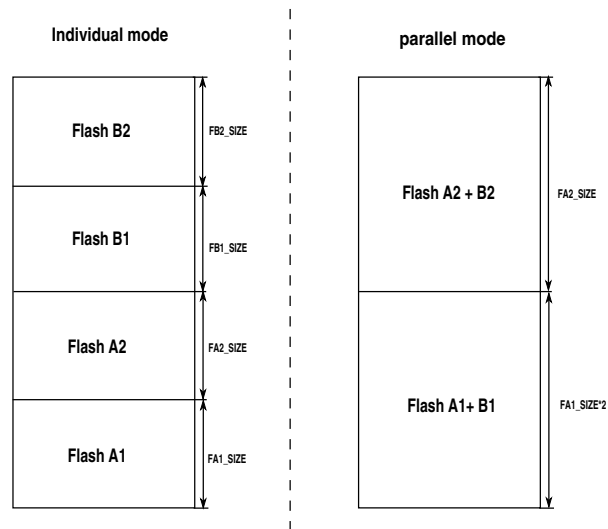

In Octal mode, flash transmit/receive data on 8 Data pin (SIO0~SIO7 for both transmitting and receiving).

Single, Dual, Quad and Octal mode is determined by instruction (num\_pads) in LUT sequence dynamically. There is no static configuration register field setting for Single, Dual, Quad and Octal mode.

## 26.7.5 Flash memory map

Flash memory map in individual and parallel mode is as following:

**Figure 26-4. Flash memory map in individual and parallel mode**

Flash memory map in individual mode:

- Flash A1 address range:  $0x00000000 \sim FA1\_SIZE$
- Flash A2 address range:  $FA1\_SIZE \sim (FA1\_SIZE + FA2\_SIZE)$
- Flash B1 address range:  $(FA1\_SIZE + FA2\_SIZE) \sim (FA1\_SIZE + FA2\_SIZE + FB1\_SIZE)$
- Flash B2 address range:  $FA1\_SIZE + FA2\_SIZE + FB1\_SIZE \sim (FA1\_SIZE + FA2\_SIZE + FB1\_SIZE + FB2\_SIZE)$

Flash memory map in parallel mode:

- Flash A1+B1 address range:  $0x00000000 \sim FA1\_SIZE*2$
- Flash A2+B2 address range:  $FA1\_SIZE*2 \sim (FA1\_SIZE*2 + FA2\_SIZE*2)$

### NOTE

- When  $MCR0[SAMEDEVICEEN]$  is set to 0x1,  $FA1\_SIZE/FA2\_SIZE/FB1\_SIZE/FB2\_SIZE = FLSHA1CR0[FLASHSZ] * 1KByte$
- When  $MCR0[SAMEDEVICEEN]$  is set to 0x0,  $FA1\_SIZE = FLSHA1CR0[FLASHSZ] * 1KByte$ ;  $FA2\_SIZE = FLSHA2CR0[FLASHSZ] * 1KByte$ ;  $FB1\_SIZE =$

FLSHB1CR0[FLASHSZ] \* 1KByte; FB2\_SIZE =  
 FLSHB2CR0[FLASHSZ] \* 1KByte

- Flash B1/B2 size setting are ignored in parallel mode (FLSHB1CR0.FLASHSZ, FLSHB2CR0.FLASHSZ). To support parallel mode application, Flash B1 should be same device as A1 and Flash B2 should be same device as A2.

### 26.7.6 Flash address sent to Device

Flash access start address is determined by AHB address (AHB command) or IPCR0[SFAR] register (IP command). Refer [Flash access by AHB Command](#) and [Flash access by IP Command](#) for more details.

FlexSPI controller will remove flash base address automatically when sending flash address to devices. Flash address is sent to devices in two part: Row Address and Column Address. For flash devices not supporting Column address, please set register field FLSHxCR1[CAS] to 0. Then all flash address bits will be sent to Flash device as Row address. For flash device supporting word-addressable feature, the last bit of flash address is not needed because flash is read/programmed in terms of 2 bytes. For parallel mode, Flash A1/B1 (or A2/B2) is accessed parallelly, so the flash address sent to flash device should be divided by 2. Following table indicates the relationship of Row/Column Address and flash address (FA)

**Table 26-6. Flash Row/Column Address**

Parallel mode	Word-addressable	Row Address	Column Address	Comment
0	0	FA[31:CAS]	FA[CAS-1:0]	There is no limitation on FA and data size alignment.
0	1	FA[31:CAS+1]	FA[CAS:1]	FA and data size should be 2 byte aligned.
1	0	FA[31:CAS+1]	FA[CAS:1]	FA and data size should be 2 byte aligned.
1	1	FA[31:CAS+2]	FA[CAS+1:2]	FA and data size should be 4 byte aligned.

**NOTE**

- FA is the flash address with flash base address removed.
- If the Row/Column Flash Address bit number to be sent to Flash device defined in Instructions is more than valid Row/Column Flash Address bit number, high position bits

will be supplemented with zero. Refer [Programmable Sequence Engine](#) for more details about Row/Column Address instruction.

When parallel mode enabled or word-addressable flash used, there is limitation on flash start address and data size. This requirement could be met by aligning AHB bus access address (For AHB command) or IP command address IPCR0[SFAR] (For IP command) in software. There are two ways to avoid these limitation in specified case.

1. For **AHB Read Command** only:

When AHBCR[READADDROPT] and AHBCR[PREFETCHEN] are both set to 1, FlexSPI will guarantee flash access start address and data size are 64 bit aligned by hardware.

When AHBCR[READADDROPT] is set to 1, FlexSPI will fetch redundant data to guarantee flash start address aligned with 8 bytes. When prefetch enabled (AHBCR[PREFETCHEN] is set to 1), flash read data size is determined by AHB RX Buffer size which is 64 bit aligned.

2. For **AHB Write Command and Individual mode** only:

By default, FlexSPI will guarantee flash write access start address and data size are 16 bit aligned by using DQS as write mask.

This feature is not applied in parallel mode and should be used only if external device supports write mask feature.

### 26.7.7 Look Up Table

The LUT (Look Up Table) is an internal memory to preserve a number of pre-programmed sequences. Each sequence consists of up to 8 instructions which are executed sequentially. When a flash access is triggered by an IP command or an AHB command, FlexSPI controller will fetch the sequence from LUT according to sequence index/number and execute it to generate a valid flash transaction on SPI interface.

Following figure indicates the structure of LUT, sequence and instruction.

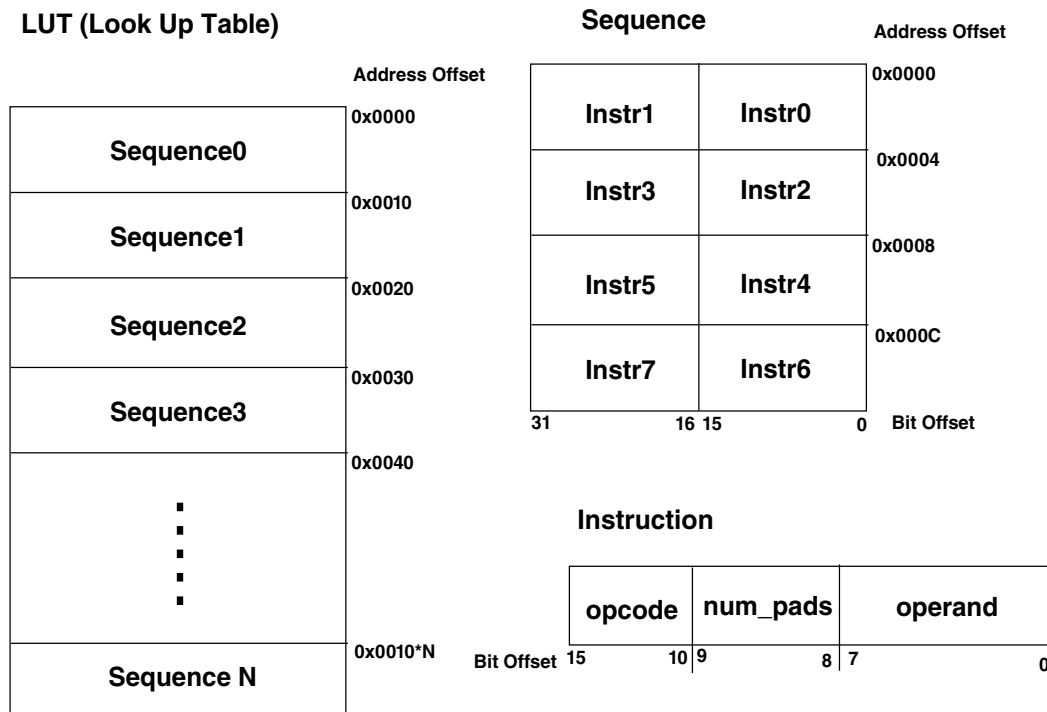

Figure 26-5. LUT and sequence structure

**NOTE**

If the instruction number needed is less than 8 for a flash transaction, STOP instruction should be programmed for the unneeded instructions (instruction code 8'h00).

For IP command and AHB write command, FlexSPI controller always executes from instruction pointer 0; For AHB read command, FlexSPI controller executes from a saved instruction start pointer. FlexSPI controller saves the instruction start pointers separately for each flash device. All these saved instruction pointer are zero before JMP\_ON\_CS instruction executed,. When JMP\_ON\_CS instruction executed, the operand in JMP\_ON\_CS instruction will be saved as instruction start pointer. Refer [Execute-In-Place Enhance mode](#) for more details.

The reset value of LUT is unknown because it is implemented as internal memory. LUT should be programmed according to the device connected on board. In order to protect its contents during a code runover the LUT could be locked/unlocked to avoid change by mistake after programmed. The key for locking or unlocking the LUT is **0x5AF05AF0**. The process for locking and un-locking the LUT is as follows:

**Locking the LUT**

1. Write the key (**0x5AF05AF0**) in to the LUT Key Register [LUT Key Register \(LUTKEY\)](#).

- Write 2b01 to the LUT Control Register field LOCK and UNLOCK LUT Key Register (LUTKEY) immediately after above KEY register writing. LUT is not successfully locked if there is any other register write access to FlexSPI between these two write access.

### Unlocking the LUT

- Write the key (0x5AF05AF0) in to the LUT Key Register LUT Key Register (LUTKEY).
- Write 2b10 to the LUT Control Register field LOCK and UNLOCK LUT Key Register (LUTKEY) immediately after above KEY register writing. LUT is not successfully unlocked if there is any other register write access to FlexSPI between these two write access.

The lock status of the LUT can be read from register field LUTCR[LOCK] and LUTCR[UNLOCK].

## 26.7.8 Programmable Sequence Engine

FlexSPI controller implements a programmable sequence engine that execute the sequence from LUT. FlexSPI controller executes the instructions sequentially and generate flash transaction on SPI interface accordingly. Following table is a complete list of supported instructions.

**Table 26-7. Instruction set**

Name	Opcode	Num_pads	Action on SPI interface	Transmit Data	Bits/Bytes/Cycle Number
CMD_SDR/ CMD_DDR	6'h01/ 6'h21	2'h0 - one pad (Single mode)  2'h1 - two pad (Dual mode)	Transmit Command code to Flash	Command code: Operand[7:0]	Bit number: 8
RADDR_SDR/ RADDR_DDR	6'h02/ 6'h22	2'h2 - four pad (Quad mode)  2'h3 - eight pad (Octal mode)	Transmit Row Address to Flash	Row_Address[31:0]	Bit number: operand[7:0]
CADDR_SDR/ CADDR_DDR	6'h03/ 6'h23		Transmit Column Address to Flash	Column_Address[31:0]	Bit number: operand[7:0]
MODE1_SDR/ MODE1_DDR	6'h04/ 6'h24		Transmit Mode bits to Flash	Mode bits: Operand[0]	Bit number: 1
MODE2_SDR/ MODE2_DDR	6'h05/ 6'h25			Mode bits:	Bit number: 2

*Table continues on the next page...*

Table 26-7. Instruction set (continued)

Name	Opcode	Num_pads	Action on SPI interface	Transmit Data	Bits/Bytes/Cycle Number
MODE2_DDR	6'25			Operand[1:0]	
MODE4_SDR/ MODE4_DDR	6'h06/ 6'h26			Mode bits: Operand[3:0]	Bit number: 4
MODE8_SDR/ MODE8_DDR	6'h07/ 6'h27			Mode bits: Operand[7:0]	Bit number: 8
WRITE_SDR/ WRITE_DDR	6'h08/ 6'h28		Transmit Programming Data to Flash	Programming Data in IP TX FIFO or AHB_TX_BUF	Byte number (data size) is determined by AHB burst size and burst type (AHB Command) or IPCR1.DATSZ (IP command). For more detail about flash read/program data size, refer <a href="#">Flash access by AHB Command</a> and <a href="#">Flash access by IP Command</a> .
READ_SDR/ READ_DDR	6'h09/ 6'h29		Receive Read Data from Flash  Read Data is put into AHB_RX_BUF or IP_RX_FIFO.	-	
LEARN_SDR/ LEARN_DDR	6'h0A/ 6'h2A		Receive Read Data or Preamble bit from Flash device  FlexSPI Controller will compare the data line bits with DLPR register to determine a correct sampling clock phase.	-	Byte number: operand[7:0]  Never set operand to zero for LEARN instruction.
DATSZ_SDR/ DATSZ_DDR	6'h0B/ 6'h2B		Transmit Read/Program Data size (byte number) to Flash	Internal Logic  Read/Program data size for current command sequence.	Bit number: operand[7:0]  Please never set operand to zero or larger than 64 for DATSZ instruction.
DUMMY_SDR/ DUMMY_DDR	6'h0C/ 6'h2C		Leave data lines undriven by FlexSPI controller. Provide turnaround cycles from host driving to device driving. num_pads will determine the number of pads in input mode.	-	Dummy cycle number (in serial root clock): Operand[7:0]  <b>Dummy cycle (N) described in Flash device datasheet is in number of SCK cycle and this number may be configurable.</b>  <b>In SDR mode, SCK cycle is same as serial root clock. The operand value should be set as N.</b>  <b>In DDR mode, SCK cycle is double to serial root clock cycle. The operand</b>

Table continues on the next page...

Table 26-7. Instruction set (continued)

Name	Opcode	Num_pads	Action on SPI interface	Transmit Data	Bits/Bytes/Cycle Number
					value should be set as $2*N$ , $2*N-1$ or $2*N+1$ depending on how dummy cycle defined in device datasheet. Please refer to <a href="#">Flash access sequence example</a> and dummy cycle definition on device datasheet.
DUMMY_RWDS_SDR/ DUMMY_RWDS_DDR	6'h0D/ 6'h2D		This instruction is similar as DUMMY_SDR/ DUMMY_DDR instruction. But the dummy cycle number is different.  DQS pins is called "RWDS" in HyperBus specification. Refer <a href="#">Dummy instruction</a> for more details.  <b>Set operand as "Latency count" for HyperBus devices.</b>	-	For read command, dummy cycle number (in serial root clock):  (operand[7:0]*4-1) if RWDS (DQS pin) is high;  (operand[7:0]*2-1) if RWDS (DQS pin) is low;  For write command, dummy cycle number (in serial root clock):  (operand[7:0]*4-2) if RWDS (DQS pin) is high;  (operand[7:0]*2-2) if RWDS (DQS pin) is low;
JMP_ON_CS	6'h1F	Num_pads setting will be ignored.  Always set num_pads to 2'h0.	Stop execution, deassert CS and save operand[7:0] as the instruction start pointer for next sequence.  Normally this instruction is used to support Execute-In-Place enhance mode. Refer <a href="#">Execute-In-Place Enhance mode</a> for more details.  This instruction is only allowed for AHB read command. If this instruction is used in IP command or AHB write command, there will be interrupt status bit set (INTR[PCMDERR] or INTR[AHBCMDERR]).	-	No transaction on SPI interface.
STOP	6'h00		Stop execution, deassert CS. Next command sequence (to the same flash device) will started from instruction pointer 0.	-	

The programmable sequence engine allows the software to configure the FlexSPI LUT according to external serial device connected on board. The flexible structure is easily adaptable to new command/protocol changes from different vendors.

DDR sequence is a flash access sequence that contain DDR instruction which is not DUMMY, it may contain SDR instructions optionally. SDR sequence is a flash access sequence that don't contain any DDR instruction. FlexSPI controller determines instruction SDR or DDR mode by decoding bit 5 of instruction opcode. The output/input timing on FlexSPI is different for SDR and DDR sequences. Especially note that SDR instruction in SDR sequence and DDR sequence is executed differently. Refer [FlexSPI Input Timing](#) and [FlexSPI Output Timing](#) for more details.

### 26.7.8.1 Instruction execution on SPI interface

This section describes the detail of instruction execution on SPI interface. For all instructions transmitting/receiving data bits to/from flash, the bit order in one byte is higher on SIO3 than SIO0; and higher on B port than A port.

#### 1. Command Instruction

Command Instruction (CMD\_SDR/CMD\_DDR) is normally used to transmit command code to external flash device. Command code is the 8 bits operand in instruction. Command code will be send to both B port and A port in parallel mode. Refer [Flash access sequence example](#) for examples.

#### 2. Address Instruction

Address Instructions (RADDR\_SDR/RADDR\_DDR/CADDR\_SDR/CADDR\_DDR) are normally used to send Flash access start address (Row/Column Address) to external flash device. Row/Column Address bits are determined by FlexSPI according to AHB access address or IP command address. Refer [Flash address sent to Device](#) for more details. The bit number is the operand value in instruction code. Row/Column address bits will be send to both B port and A port in parallel mode. Refer [Flash access sequence example](#) for examples.

#### 3. Mode Instruction

Mode Instructions (MODE<sub>x</sub>\_SDR/MODE<sub>x</sub>\_DDR) are normally used to send mode bits to external flash device. Mode bits are the (lower) bits value of the instruction operand. The transition bit number is 1 for MODE1\_SDR/MODE1\_DDR, 2 for MODE2\_SDR/MODE2\_DDR, 4 for MODE4\_SDR/MODE4\_DDR and 8 for MODE8\_SDR/MODE8\_DDR. Note that pad number should be no more than mode bit number. For example, it is not allowed to set num\_pads to 2'b11 (Octal mode) for MODE4\_\* instructions. Mode bits will be send to both B port and A port in parallel mode. Refer [Flash access sequence example](#) for examples.

#### 4. Data Size Instruction

Data Size Instructions (DATSZ\_SDR/DATSZ\_DDR) are used to send program/read data size (byte number) to external device. This instruction is normally used in FPGA application when the memory space in external device acts similar as a FIFO. The device needs data size information to determine how much data will be popped from or pushed into internal FIFO. The bit number is the operation value in the instruction. Data size bits will be send to both B port and A port in parallel mode. Refer [Flash access sequence example](#) for examples.

## 5. Write Instruction

Write Instructions (WRITE\_SDR/WRITE\_DDR) are normally used to send program data to external device. Programming data are fetched from IP TX FIFO (IP Command) or AHB TX Buffer (AHB command). For more details about flash program data size, refer [Flash access by AHB Command](#) and [Flash access by IP Command](#). The byte order for programming date is always from low to high. Odd bytes are send on A port and Even bytes are send on B port in parallel mode. Refer [Flash access sequence example](#) for examples.

## 6. Read Instruction

Read Instructions (READ\_SDR/READ\_DDR) are normally used to receive flash data from external device. Received data will be put into IP RX FIFO (IP Command) or AHB RX Buffer f(AHB command). For more detail about flash read data size, refer [Flash access by AHB Command](#) and [Flash access by IP Command](#). The byte order for reading date is always from low to high. Odd bytes are received from A port and Even bytes are received from B port in parallel mode. Refer [Flash access sequence example](#) for examples.

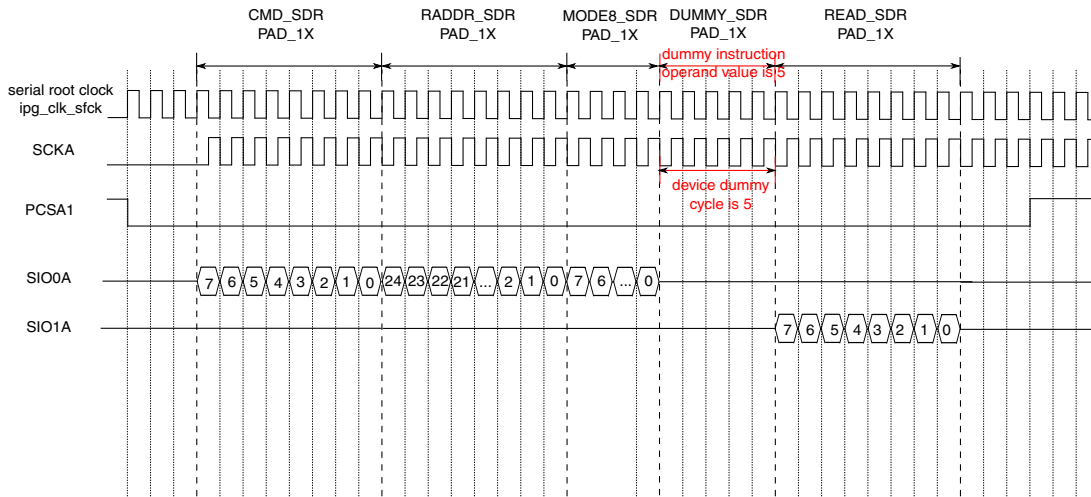

## 7. Dummy Instruction

Dummy Instructions (DUMMY\_SDR/DUMMY\_DDR/DUMMY\_RWDS\_SDR/DUMMY\_RWDS\_DDR) are used to provide turnaround cycles on SPI interface. During dummy instruction, neither FlexSPI controller nor external device drives SPI interface. Refer [Programmable Sequence Engine](#) for more details about dummy cycle number.

DUMMY\_RWDS\_DDR could be used for HyperBus device which use "RWDS" pin to indicate whether extra latency count needed. DUMMY\_RWDS\_SDR is reserved for future. FlexSPI controller checks DQS pin input level at the 4th cycle after SCK output toggling enabled. DQS pins is called "RWDS" in HyperBus specification. Refer [Flash access sequence example](#) for examples.

### 26.7.8.2 Flash access sequence example

Following is an example for SDR single I/O Read sequence (Spansion Serial Nor Flash S25FS512S) in individual mode.

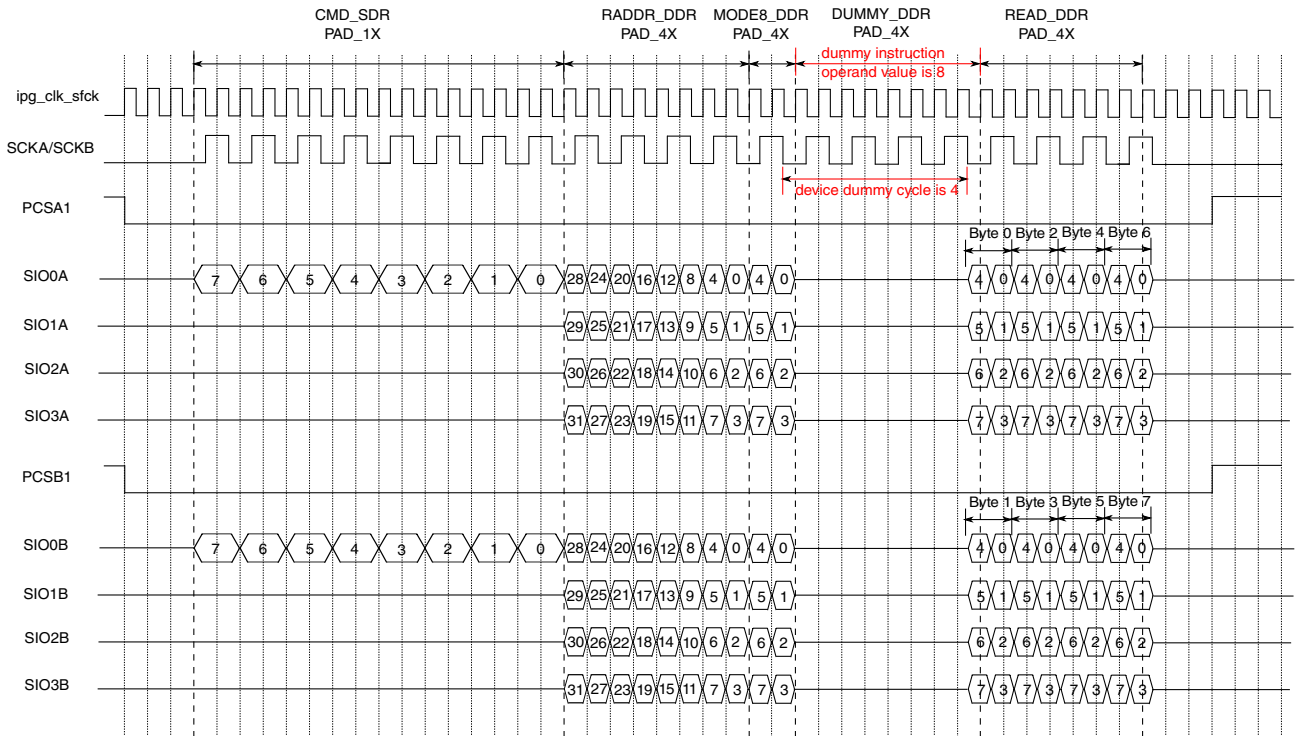

**Figure 26-6. Flash access sequence example (SDR Single I/O Read sequence)**

Following is an example for SDR Quad I/O Read sequence (Spansion Serial Nor Flash S25FS512S) in individual mode.

**Figure 26-7. Flash access sequence example (SDR Quad I/O Read sequence)**

Following is an example for DDR Quad I/O Read sequence (Spansion Serial Nor Flash S25FS512S) in parallel mode.

**Figure 26-8. Flash access sequence example (DDR Quad I/O Read sequence)**

Following is an example for HyperBus device read transaction (Single latency count) in individual mode.

Following is an example for HyperBus device read transaction (Additional latency count) in individual mode.

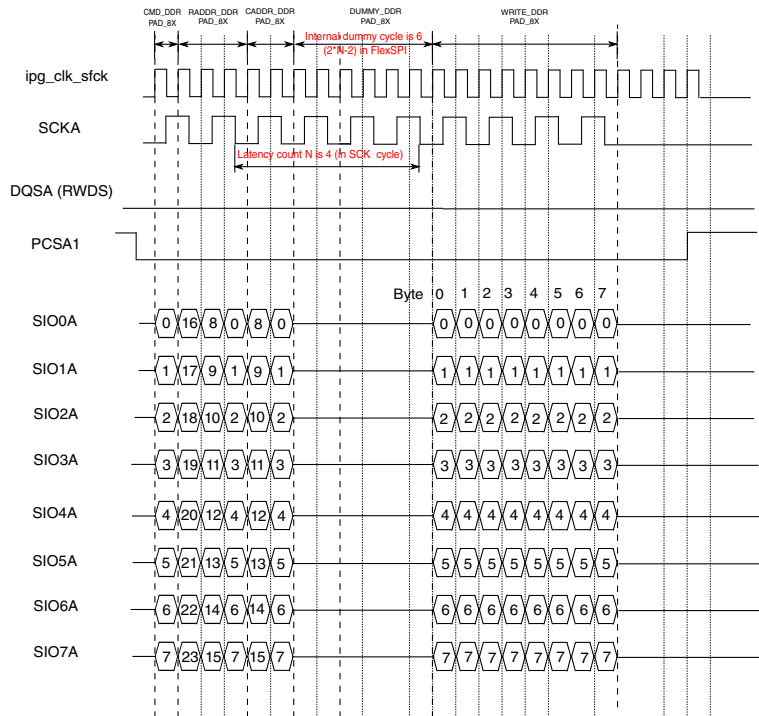

Figure 26-10. HyperBus device read transaction with additional latency count

Following is an example for HyperBus device write transaction (Single latency count) in individual mode.

**Figure 26-11. HyperBus device write transaction with single latency count**

Following is an example for HyperBus device write transaction (Additional latency count) in individual mode.

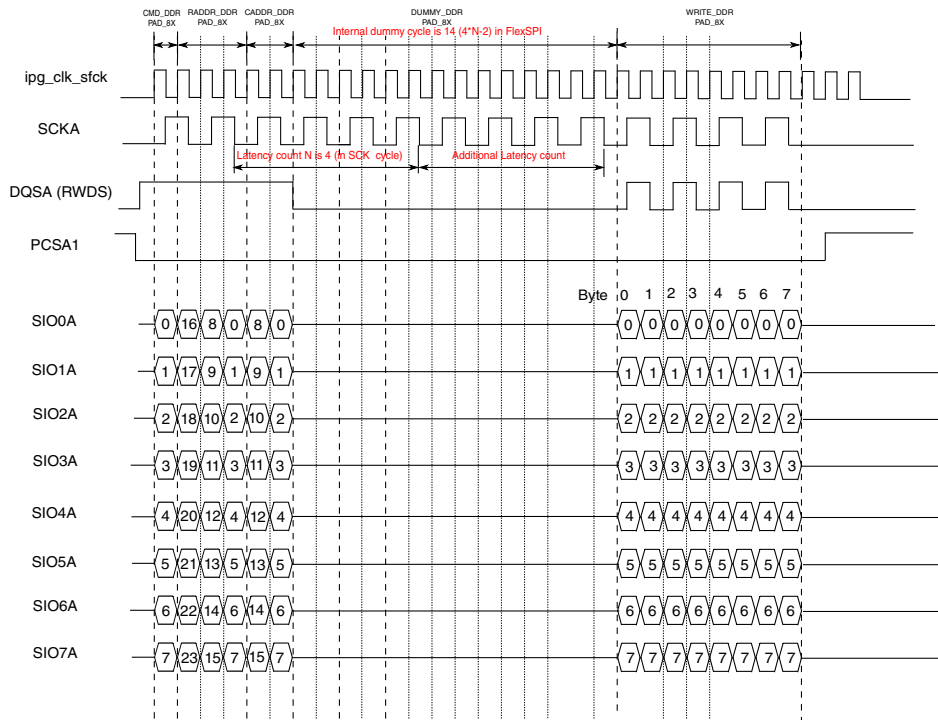

Figure 26-12. HyperBus device write transaction with additional latency count

### 26.7.9 Flash access by IP Command

Flash access could be triggered by IP command in following steps.

- Fill IP TX FIFO with programming data if this is a programming command (programming flash data, flash status registers etc.)
- Set flash access start address (IPCR0), read/program data size, sequence index in LUT and sequence number (IPCR1).
- Trigger flash access command by writing 1 to register bit IPCMD[TRG]
- Polling register bit IPCMDDONE to wait for this IP command finished on FlexSPI interface.

#### NOTE

- IP TX FIFO could be filled before or after writing IPCR0/ IPCR1/IPCMD register. If SFM command is started with IP TX FIFO empty, FlexSPI will stop SCK toggling to wait for TX data ready automatically.
- IPCMD register must be written after writing IPCR0/ IPCR1 register.

- Multiple Command sequences (8 at most) could be issued by one IP command.
- It's not allowed to issue another IP command before previous IP command finished. The behaviour is unknown in this case.

If this is a Reading command to Serial Flash Memory, all reading data from Flash will be put into IP RX FIFO. Software need to read out data from IP RX FIFO by AHB bus or IP Bus. When IP RX FIFO is full and there is more data to be read from Flash device, FlexSPI will stop SCK output clock toggling until IP RX FIFO is not full. Please refer to [SCK stop feature](#) for more detail.

The detail of triggered Serial Flash Command is as following:

- Flash access start address:  
Determined by register field IPCR0.SFAR.
- Flash Chip Select:  
Determined by flash access address and Flash size setting (FLSHxCR0[FLSHSZ]).
- Flash command Sequence Index and Sequence Number:  
The sequences indexed from IPCR1[ISEQID] to (IPCR1[ISEQID] + IPCR1[ISEQNUM]) in LUT will be executed by FlexSPI sequentially.
- Flash Individual/Parallel access mode:  
Determined by IPCR1[IPAREN].
- Flash Read/Program Data Size:
  - If IPCR1[IDATSZ] value is non-zero, flash read/program data size (in byte) is IPCR1[DATSZ].
  - If IPCR1[IDATSZ] value is zero, flash read/program data size (in byte) will be the operand value in the READ/WRITE instruction.

#### NOTE

- Software should make sure the last sequence index never exceeds the LUT sequence number (IPCR1[ISEQID] + IPCR1[ISEQNUM] < 16).
- Data size is applied to every command sequence if sequence number is more than one.
- Data size is ignored if there is no WRITE/READ instruction in the command sequence .

IP command request is sent to arbitrator after triggered by software. It is not executed on FlexSPI Interface until granted by arbitrator. Please refer to [Command Arbitration](#) for more details.

### 26.7.9.1 Reading Data from IP RX FIFO

FlexSPI put the read data from external device into IP RX FIFO for IP command. These data could be read out by following two memory space access.

- 100 - 180 (by IPS Bus)
- 7FC00000 - 7FC00080 (by AHB Bus)

If MCR0[ARDFEN] is set to 0x1, read data in IP RX FIFO could only be read out by AHB Bus, IP Bus read access to IP RX FIFO will always return with data zero and no bus error occur.

If MCR0[ARDFEN] is set to 0x0, read data in IP RX FIFO could only be read out by IPS Bus, AHB Bus read access to IP RX FIFO will trigger bus error.

FlexSPI push read data into IP RX FIFO in terms of 64 bits every time it receives 64 bits data from external device. When read data bits number is not 64 bits aligned, FlexSPI will push addition zero bits into IP RX FIFO for the last push.

IP RX FIFO could be read by processor or DMA. Following is the detail flow for processor and DMA reading:

#### 1. Reading by processor

To read by processor, following register settings are needed:

- Set register field IPRXFCR[DMAEN] to 0.
- Set WaterMark level by IPRXFCR[WMRK], watermark level is  $(IPRXFCR[WMRK]+1)*8$  bytes.
- Set register field INTEN[IPRXWA] to enable IP RX FIFO watermark available interrupt (optionally).

Processor needs to poll register INTR[IPRXWA] or wait for IP RX FIFO Watermark Available interrupt before reading IP RX FIFO. This is to make sure there is a watermark level Data filled in IP RX FIFO before reading.

After reading a watermark level datas from IP RX FIFO, software need to set register bit INTR[IPRXWA]. This set action will pop out a watermark level datas from IP RX FIFO.

Following digram indicates the reading flow from IP RX FIFO by processor.

**Figure 26-13. Reading IP RX FIFO by processor**

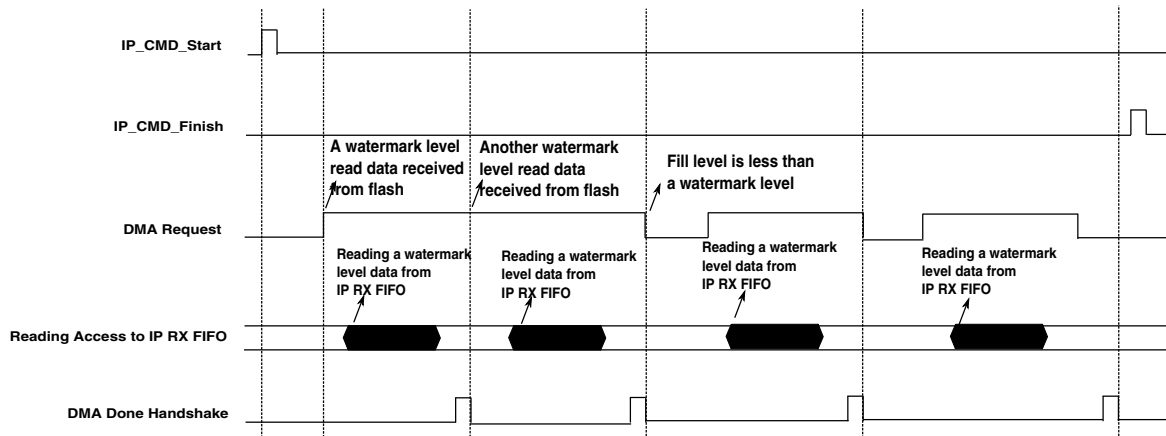

### NOTE

- Processor need to read out a watermark level datas from IP RX FIFO each time before set register bit INTR[IPRXWA].
- It's supported that the total flash read/program data size is not multiple of watermark level. In this case, the reading data size from IP RX FIFO will be less than a watermark level for the last time, software should poll IPRXSTS[FILL] field instead of polling INTR[IPRXWA]. After copying all datas from IP RX FIFO and all command sequences to Flash are finished (INTR[IPCMDDONE]=1), software should clear IP RX FIFO by set IPRXFCR[CLRRXF]. Otherwise the reading data will be wrong for the next Reading Command to Flash.
- IP RX FIFO data is not popped out by each reading access to IP RX FIFO, but popped by writing 0x1 to register INTR[IPRXWA] bit.

## 2. Reading by DMA

To read IP RX FIFO by DMA, following setting is needed:

- Set register field IPRXFCR[DMAEN] to 1.
- Set WaterMark level by IPRXFCR[WMRK], watermark level is  $(IPRXFCR[WMRK]+1)*8$  bytes.
- Set DMA transfer Minor loop size to same watermark level.

**Figure 26-14. Reading from IP RX FIFO by DMA**

**NOTE**

- DMA request is generated when the fill level of IP RX FIFO is higher than (or equal) watermark level. This request is not pulse valid but level valid.
- DMA should read out a watermark level datas from IP RX FIFO each time (set minor loop size with the same value as watermark level).
- DMA need to return a Done handshake (pulse valid) to FlexSPI each time it finished reading a watermark level datas.
- IP RX FIFO data is not popped out by each reading access, but popped by DMA done handshake.
- It's not supported that the total read/write data size (Major loop size) is not multiple of watermark level. Because DMA don't know when the data is ready for the last reading. It makes DMA driver too complex to polling IPRXFSTS[FILL] field.

**26.7.9.2 Filling Data to IP TX FIFO**

The programming should be put into IP TX FIFO and then transmit to Flash by FlexSPI. It could be filled by two memory space.

- 0x180 - 0x200 (by IP Bus)
- 7F800000 - 7F800080 (by AHB Bus)

To fill by AHB Bus, need to set MCR0[ATDFEN] to 1, IP Bus write access to IP TX FIFO will be ignored, but no bus error.

To fill by IP Bus, need to set MCR0[ATDFEN] to 0, AHB Bus write access to IP TX FIFO will return Bus Error.

IP TX FIFO is popped with 64 bits data every time FlexSPI fetch data for transmitting. If the programming data size is not multiple of 64 bits, last popped valid bits will be less than 64 bits. But there is no problem because these invalid bits is not transmit to Flash at all.

IP TX FIFO could be filled by processor or DMA.

To fill by processor, need following setting:

- Set register field IPTXFCR[DMAEN] to 0.
- Set WaterMark level by IPTXFCR[WMRK], watermark level is  $(IPTXFCR[WMRK]+1)*8$  bytes.
- Set register field INTEN[IPTXWE] to enable IP TX FIFO watermark empty interrupt (optionally).

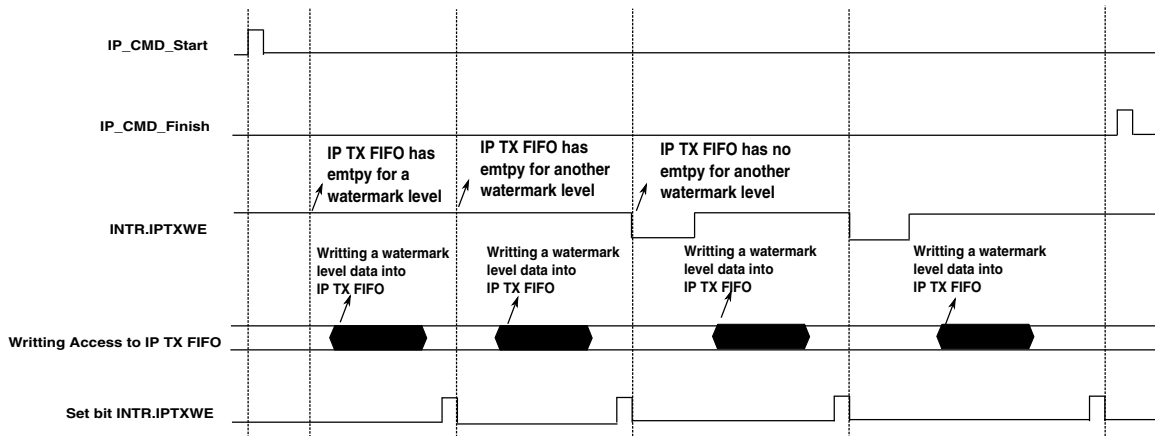

Processor needs to poll register INTR[IPTXWE] or wait for IP TX FIFO Watermark empty interrupt before filling IP TX FIFO. This is to make sure there is enough space for a watermark level Data filling before filling.

After filling a watermark level datas to IP TX FIFO, need to set register bit INTR[IPTXWE]. This will push a watermark level datas into IP TX FIFO (write pointer is incremented).

### NOTE

IP TX FIFO data is not pushed by each write access, only pushed by set INTR[IPTXWE] bit.

Following digram indicates the filling flow to IP TX FIFO by processor.

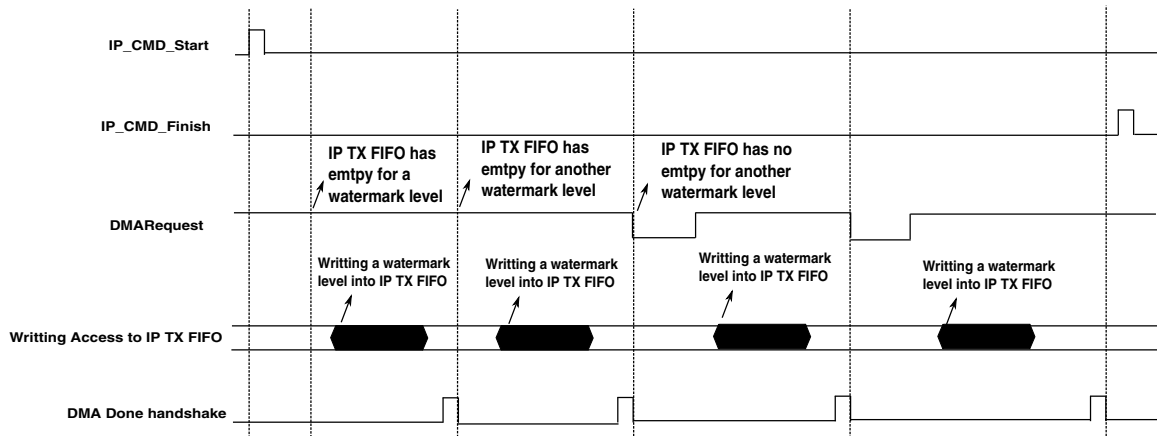

**Figure 26-15. Filling IP TX FIFO by processor**

**NOTE**

- Processor need to fill a watermark level datas to IP TX FIFO each time.
- It's allowed that total write data size is not multiple of watermark level. In this case, the writing size will be less than a watermark level for the last time. After filled all datas into IP TX FIFO and all Command Sequences to Flash are finished (INTR[IPCMDDONE]=1), processor should clear IP TX FIFO by set IPTXFCR[CLRRTXF]. Otherwise, the programming data will be wrong for the next programming Command to Flash.

To fill IP TX FIFO by DMA, need following setting:

- Set register field IPTXFCR[DMAEN] to 1.
- Set WaterMark level by IPTXFCR[WMRK], watermark level is  $(IPTXFCR[WMRK]+1)*8$  bytes.
- Set DMA transfer Minor loop size to same watermark level.

**Figure 26-16. Filling from IP TX FIFO by DMA**

### NOTE

- DMA request is generated when there is empty space more than watermark level in IP TX FIFO. This request is not pulse valid but level valid.
- DMA should fill watermark level datas into IP TX FIFO each time (set minor loop size with the same value as watermark level).
- DMA need to return a Done handshake (pulse valid) to FlexSPI each time it finished filling a watermark level datas.
- IP TX FIFO data is not pushed in by each reading access, but pushed by DMA done handshake.
- It's allowed that total program data size (Major loop size) is not multiple of watermark level. After filled all datas into IP TXFIFO and all command sequences to Flash are finished ( $\text{INTR}[\text{IPCMDDONE}] = 1$ ), need to clear IP TX FIFO by set  $\text{IPTXFCR}[\text{CLRTRXF}]$ . Otherwise, the programming data will be wrong for the next programming Command to Flash.

## 26.7.10 Flash access by AHB Command

Flash could be accessed by AHB bus directly on AHB address space: 60000000~0x80000000. This address space is mapped to Serial Flash Memory in FlexSPI. AHB bus access to this address space may trigger Flash access command sequence as needed.

## Functional description

For AHB read access to Serial Flash Memory, FlexSPI will fetch data from flash into AHB RX Buffers and then return the data on AHB Bus. For AHB write access to Serial Flash Memory, FlexSPI will buffer AHB Bus write data into AHB TX Buffer and then transmit to Serial Flash memory.

There is no software configuration or polling need for AHB command except FlexSPI initialization. AHB master access external flash device transparently similar as normal AHB slave.

AHB command is normally used to access serial Flash memory space. IP command should be used to access the control and status registers or other spaces such as OTP in external flash device.

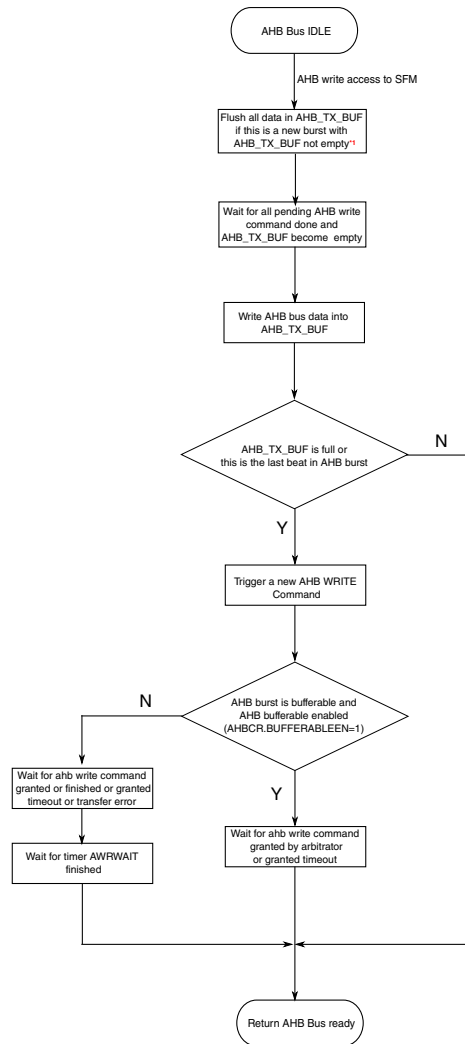

Following section described AHB command for read and write in more detail.

### **NOTE**

When FlexSPI controller return AHB bus error for SFM access, AHB master should stop following access beats in current burst.

#### **26.7.10.1 AHB write access to Flash**

For AHB write access to Flash, FlexSPI will buffer the write data from AHB bus into internal AHB TX Buffer and then transmit them to Flash. FlexSPI only buffers write datas for one AHB burst. Following diagram indicates the hardware operation in response to AHB write access to Flash.

**Figure 26-17. Hardware operation in response to AHB write access to Flash**

FlexSPI triggers new AHB write command in following cases:

- This beat is the last one in current AHB burst (any burst type except INCR).
- AHB TX Buffer is full after buffering current beat data.
- AHB bus becomes IDLE or a new burst comes with AHB TX Buffer not empty.

The detail information about the triggered AHB write command:

- Flash Access Start Address:

Determined by AHB burst address. FlexSPI will record the start address for the data in AHB TX Buffer and this address will be used as flash access start address

- Flash Chip Select:

## Functional description

FlexSPI determined the chip selection by flash access start address and flash size setting.

- Flash Command Sequence Index:

Determined by FLSHxCR2[AWRSEQID].

- Flash Command Sequence Number:

Determined by FLSHxCR2[AWRSEQNUM]. If AWRSEQNUM is not zero, multiple flash access command sequences will be triggered every time for AHB write command. The sequences indexed from AWRSEQID to (AWRSEQID + AWRSEQNUM) in LUT will be executed sequentially.

- Flash access mode (Individual/Parallel):

Determined by AHBCR[APAREN].

- Flash Data Size:

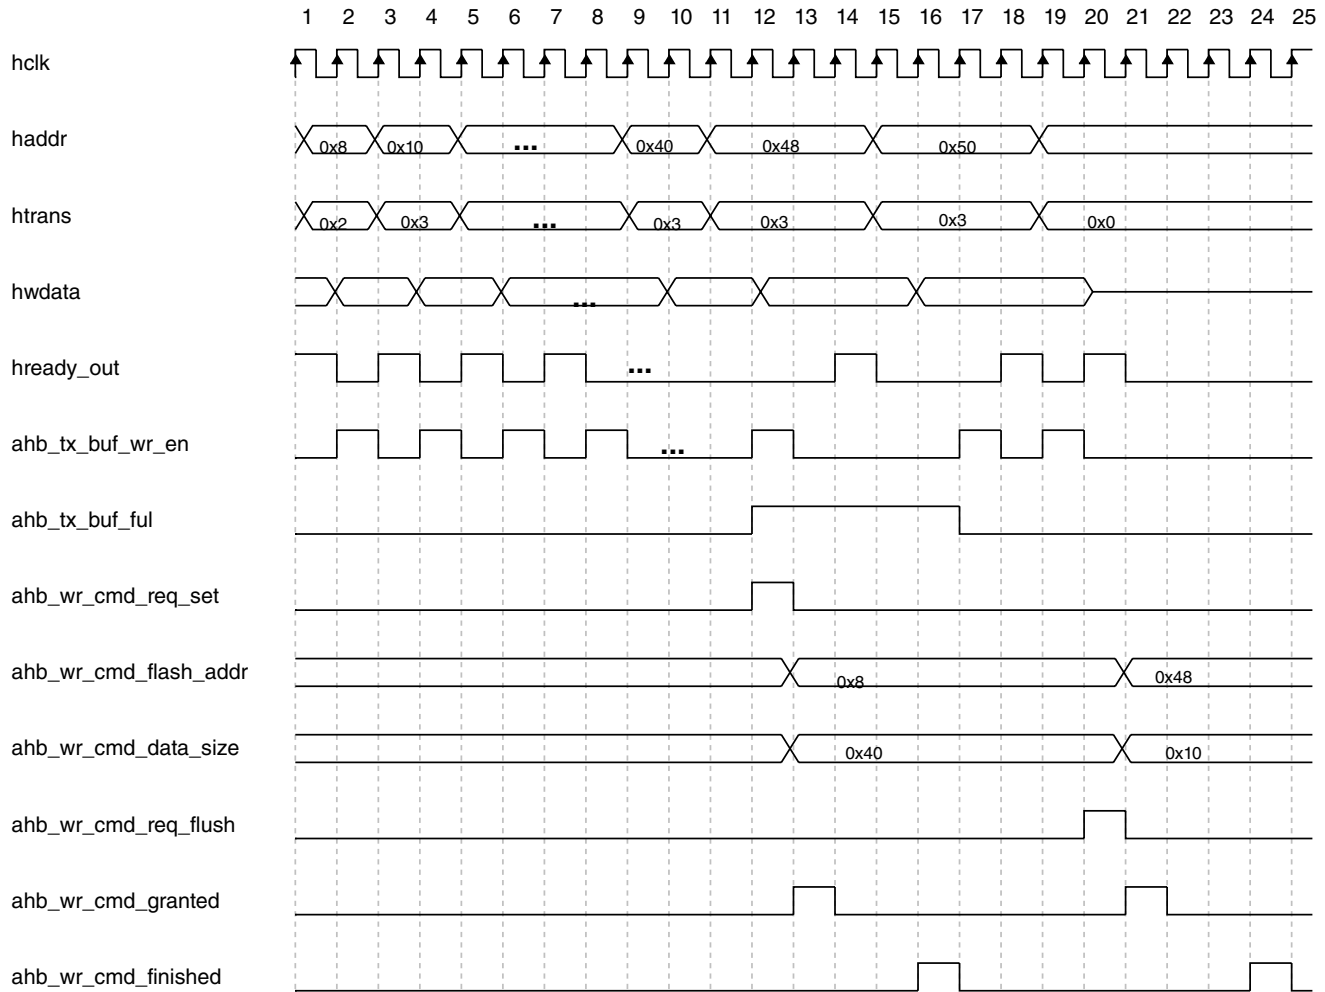

Determined by byte number of buffered data in AHB TX Buffer.

Following examples indicates internal logic for AHB write access to Flash. In these examples, AHB\_TX\_BUF is 64 Bytes (8\*64bits) .

- AHB INCR/64bit/Bufferable burst with address sequence 0x8, 0x10, 0x18, 0x20, ..., 0x50 (10 beat totally):

Two AHB write command will be triggered: the first command with flash start address 0x8 and data size 0x40; the second command with flash start address 0x48 and data size 0x10.

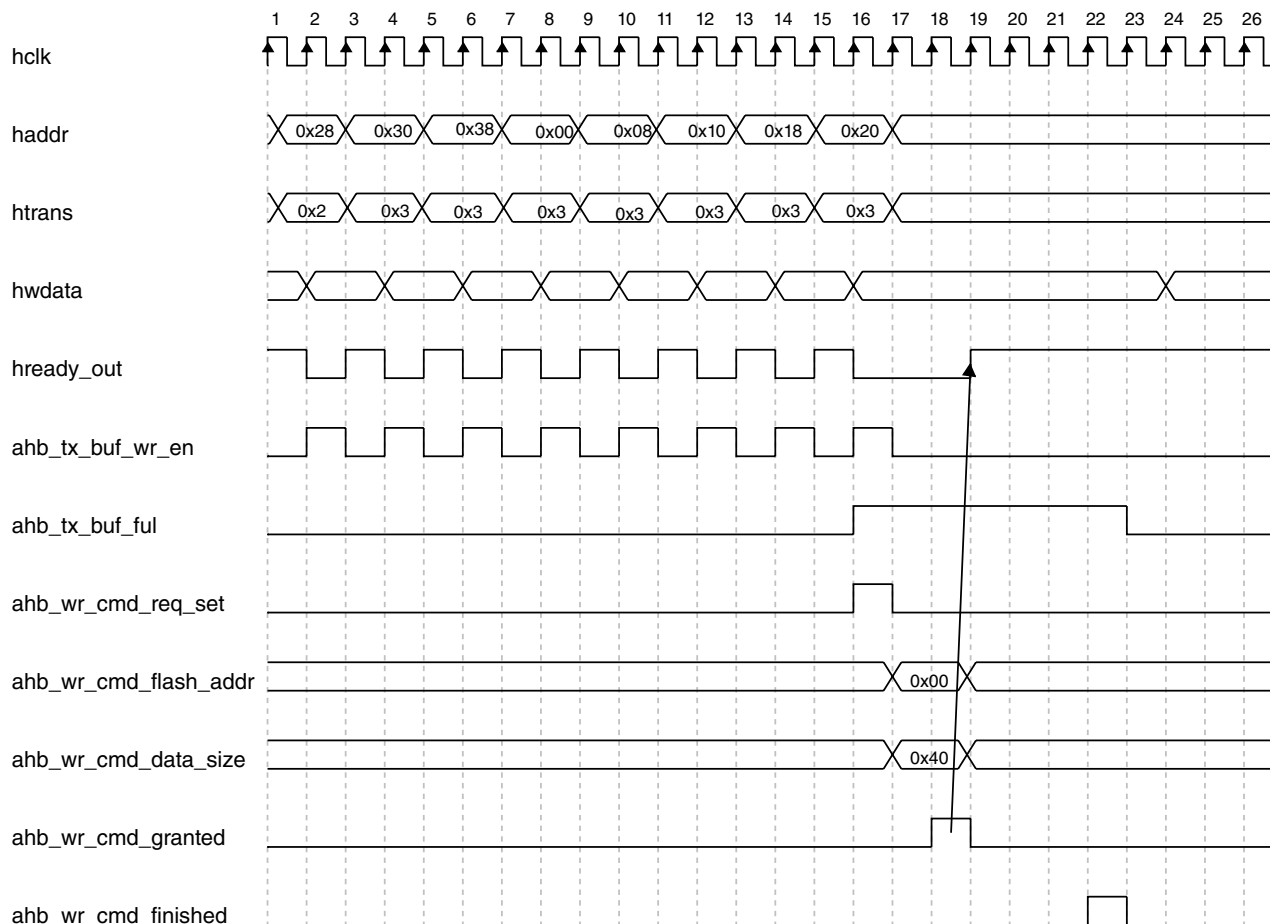

**Figure 26-18. AHB write access (INCR/64bit/Bufferable)**

- AHB WRAP8/64bit/Bufferable burst with address sequence 0x28, 0x30, 0x38, 0x0, 0x8, 0x10, 0x18, 0x20:

One AHB write command will be triggered with flash start address 0x0 and data size 0x40;

**Functional description**

**Figure 26-19. AHB write access (WRAP8/64bit/Bufferable)**

- AHB WRAP8/64bit/Non-bufferable burst with address sequence 0x28, 0x30, 0x38, 0x0, 0x8, 0x10, 0x18, 0x20:

One AHB write command will be triggered with flash start address 0x0 and data size 0x40;

**Figure 26-20. AHB write access (WRAP8/64bit/Non-Bufferable)**

### NOTE

The wrapper burst is not supported if burst data size (in byte) is larger than AHB TX Buffer size (in byte). For example, if AHB\_TX\_BUF is 64 Bytes (8\*64bits), AHB WRAP16 \* 64bit writet burst access is not supported.

### 26.7.10.2 AHB read access to Flash

For AHB read access to Flash, FlexSPI will check whether hit AHB TX Buffer/AHB RX Buffer/pending AHB read command according to the burst access type and register setting. If all these miss, FlexSPI trigger a new AHB read command to fetch data from Flash. Following diagram indicates the hardware operation in response to AHB read access to Flash.

**Figure 26-21. Hardware operation in response to AHB read access to Flash**

The detail information about the triggered AHB read command:

- Flash Access Start Address and Data Size:

Determined by AHB address, burst type and burst size. FlexSPI will fetch read data from the start address for current burst or beat.

**Table 26-8. AHB read command flash start address and data size**

Prefetch Enable	Cross flash boundary	Burst Type	Flash start address [28:0]	Data Size
0	Never cross flash boundary because AHB burst never cross 1K Byte boundary.	SINGLE/INCR4/INCR8/INCR16	hbeat_start_address	(hburst_end_address-hbeat_start_address)
		INCR	hbeat_start_address	byte size of current beat  For INCR burst with prefetch disabled, each beat is handled same as SINGLE burst.
		WRAP4/WRAP8/WRAP16	hburst_start_address	(hburst_end_address-hburst_start_address)
1	No	INCR/SINGLE/INCR4/INCR8/INCR16	hbeat_start_address	ahb_rx_buf_sz
	No	WRAP4/WRAP8/WRAP16	hburst_start_address	ahb_rx_buf_sz
	Yes	INCR/SINGLE/INCR4/INCR8/INCR16	hbeat_start_address	(flash_top_address-hbeat_start_address)
	Yes	WRAP4/WRAP8/WRAP16	hburst_start_address	(flash_top_address-hburst_start_address)

**NOTE**

- hbeat\_start\_address is HADDR input from AHB master for current beat;
- hburst\_start\_address is the lowest address for current burst; hburst\_end\_address is the highest address in current burst plus 1. For example, WRAP4 burst with HADDR 0x8,0xC, 0x0, 0x4

- ahb\_rx\_buf\_sz is the buffer size in byte of AHB RX Buffer which is used by current master.
  - flash\_top\_address is the top address of currently accessed flash
- Flash Chip Select:  
FlexSPI determined the chip selection by flash access start address and flash size setting.
  - Flash Command Sequence Index:  
Determined by FLSHxCR2[ARDSEQID].
  - Flash Command Sequence Number:  
Determined by FLSHxCR2[ARDSEQNUM]. If ARDSEQNUM is not zero, multiple flash access command sequences will be triggered every time for AHB read command. The sequences indexed from ARDSEQID to (ARDSEQID + ARDSEQNUM) in LUT will be executed sequentially.
  - Flash access mode (Individual/Parallel):  
Determined by AHBCR[APAREN].

#### NOTE

- FlexSPI determines which ARDSEQNUM/ARDSEQID fields will be used as sequence ID by flash device chip selection automatically. Refer MCR2[SAMEDEVICEEN] for more detail.
- FlexSPI determines which AHB RX Buffer used for current AHB read access by master ID. For more details about the AHB RX buffer ID and AHB master ID mapping, refer [AHB RX Buffer Management](#).
- It is not allowed to allocate AHB RX Buffer less than AHB Burst size. The behaviour is unknown for this case.

### 26.7.10.3 AHB RX Buffer Management

There are 4 buffers (Buffer 0 - Buffer 3) in AHB RX Buffer, which are transparent to AHB masters. FlexSPI fetch flash data and return on AHB Bus automatically. There is no status register polling needed for AHB read access to Serial Flash Memory.

AHB Rx Buffers total size is 1 KBytes . The buffer size is flexibly configurable for each buffer in AHB RX Buffers by register fields

AHBRXBUF0CR0[BUFSZ]~AHBRXBUF6CR0[BUFSZ]. The buffer size for Buffer 0 to Buffer 3 could be set 0. If the buffer size is set to 0x0, the related MSTRID field setting (in same AHBRXBUFxCR0 register) is ignored by FlexSPI. Buffer 3 is used for all AHB masters which is not assigned to Buffer 0 - Buffer 2. Buffer 3 size setting field (AHBRXBUF3CR0.BUFSZ) is ignored by FlexSPI, its buffer size is: AHB RX Buffer total size - sum of (Buffer 0 - Buffer 2 size).

When there is AHB read access to Serial Flash Memory, FlexSPI determine which AHB RX Buffer used as following:

1. If master ID equal AHBRXBUF0CR1[MSTRID] and AHBRXBUF0CR0[BUFSZ] is not zero, Buffer 0 will be used.
2. If master ID equal AHBRXBUF1CR1[MSTRID] and AHBRXBUF1CR0[BUFSZ] is not zero, Buffer 1 will be used.
3. If master ID equal AHBRXBUF2CR1[MSTRID] and AHBRXBUF2CR0[BUFSZ] is not zero, Buffer 2 will be used.
4. If all above case not meet, Buffer 3 will be used

#### NOTE

- Software should make sure the buffer size of each buffer is no less than the max burst size of AHB Read access from the master using this buffer. Otherwise the behaviour is undefined.
- It is not supported to assign multiple buffers for single AHB master.
- When AHB read prefetch is enabled (AHBCR[PREFETCH\_EN] is set), the prefetch data size will be determined by buffer size. FlexSPI will fetch data from external Flash with buffer size if no flash boundary across.
- AHB master priority setting (register field AHBRXBUFxCR1[PRIORITY] is used only for the suspending control of AHB prefetching. Refer [Command Abort and Suspend](#).

### 26.7.11 Command Arbitration

There are four Flash access command sources:

1. AHB Command (triggered by AHB Write access to SFM space)

2. AHB Command (triggered by AHB Read access to SFM space)
3. IP command (triggered by writing IPCMD[TRG])
4. Suspended command (AHB Read prefetch sequence which is suspended)

#### NOTE

- An AHB bus access never triggers a write command and a read command at the same time.
- AHB prefetch sequence is an AHB Command sequence triggered by AHB Read access when AHB prefetch is enabled. After all read data fetched for current AHB read burst, FlexSPI will prefetch more data to reduce the read latency for next AHB read access. AHB command for read is never aborted while fetching read data for current AHB read burst. But AHB read command could be aborted by any new IP command or AHB command request when it's prefetching data (not for current read burst).

The granted priority of these 4 command source is as following when Arbitrator is idle (STS0[ARBIDLE]=1):

1. AHB command (Read/Write)
2. IP Command
3. Suspended Command

#### NOTE

Suspended command is not granted immediately when arbitrator is idle and no AHB/IP command request. Arbitrator will wait for N AHB clock cycle idle state before resuming the suspended command (N is the register field value in MCR2[RESUMEWAIT]). This intend to avoid AHB prefetch sequence being resumed and suspended frequently.

All command request are not granted if Arbitrator is busy in executing AHB/IP command (not suspended command), and there will AHB/IP Command granted error if the grant is timeout.

If new AHB/IP command request comes while Arbitrator is executing AHB read prefetch sequence, AHB read prefetch sequence will be aborted (but not immediately). Arbitrator will grant AHB/IP command request after AHB read prefetch sequence is aborted on FlexSPI interface and saved all internal data pointers.

### 26.7.11.1 Command Abort and Suspend

This section describes command abort and suspend mechanism.

#### 1. Command Abort

As mentioned above, AHB read prefetch sequence could be aborted if new AHB/IP command request comes.

#### 2. Command Suspend

When AHB read prefetch sequence is aborted on FlexSPI interface, FlexSPI will save this suspended sequence in following cases and resume this sequence if arbitrator is idle for enough time:

- There is no valid suspended command (Register field AHBSPNDSTS[ACTIVE] is 0x0). This is possible if there is no suspended command yet or suspended command is resumed.
- Aborted AHB read prefetch sequence is higher priority than current active suspended sequence. The priority for AHB read Command is set by register field AHBBUF<sub>x</sub>CR1[PRIORITY].

#### NOTE

Original suspended sequence will be ignored and never resumed by FlexSPI.

#### 3. Suspended Command

The suspended command (internal status) turns active when there is any AHB prefetch command aborted and suspended. It turns inactive in following cases:

- Suspended command is resumed by Arbitrator.
- There is a new AHB read command request and it's triggered by AHB master using the same AHB RX Buffer (Buffer ID).

Following is an example indicating command abort/suspend/resume flow:

**Figure 26-22. Command Instructions Execution on FlexSPI interface**

## 26.7.12 SCK stop feature

FlexSPI will stop SCK output toggling when programming data is not ready for Programming command sequence or there is no space (in internal FIFO) to receive Data for reading command sequence.

There may be certain devices don't support SCK stopped during command sequence (Chip select is valid). SCK stopping could be avoid as following:

- For Flash reading triggered by IP command
  - Never trigger a read command with data size larger than IP RX FIFO size.
  - Internal async FIFO for flash reading should never be full.

FlexSPI pop data from this async FIFO in 64 bits per AHB clock cycle, and receiving data from FlexSPI interface in serial root clock. The receiving speed is determined by Flash access mode (Single/Dual/Quad/Octal mode and Individual/Parallel mode). For example, in Octal mode and parallel mode, FlexSPI receives 16 bits per serial root clock cycle. This async FIFO is never full if AHB clock frequency is higher than 1/4 of serial root clock.

- For Flash programming triggered by IP command
  - Never trigger a program command with data size larger than IP TX FIFO size.
  - Fill all programming data into IP TX FIFO before trigger the IP command.
  - Internal async FIFO for flash programming should be never empty

FlexSPI fetch programming data into this async FIFO in 64 bits per AHB clock cycle, and transmitting data to FlexSPI interface in serial root clock. The transmitting speed is determined by Flash access mode (Single/Dual/Quad/Octal mode and Individual/Parallel mode). For example, in Octal mode and parallel mode, FlexSPI transmits 16 bits per serial root clock cycle. This async FIFO is never empty if AHB clock frequency is higher than 1/4 of serial root clock.

- For Flash reading/programming triggered by AHB command
  - Internal async FIFO for flash reading/programming should never be full/empty. The frequency ratio limitation is same as Flash reading/programming triggered by IP command.

### NOTE

- FlexSPI never trigger a AHB read command with data size larger than internal AHB RX buffer size.

- FlexSPI never trigger a AHB program command with data size larger than internal AHB TX buffer size.
- All programming data is buffered into AHB TX Buffer before triggering AHB program command in FlexSPI.

### 26.7.13 FlexSPI Output Timing

This section describes the output timing in FlexSPI.

#### 26.7.13.1 Output timing between Data and SCK

This section describes the output timing relationship of Data (on SIOA/SIOB) and SCK. There are three cases for the data output timing:

- **SDR instruction in SDR sequence**

SDR sequence is the sequence which contains only SDR intructions. In this case, all data bits last one serial root clock cycle on FlexSPI interface. Following diagram indicates the relationship of serial root clock, Data and SCK:

**Figure 26-23. SDR instruction in SDR sequence**

- **SDR instruction in DDR sequence**

DDR sequence is a flash access command sequence that contain DDR instruction which is not DUMMY, it may contain SDR instructions optionally. In the case of SDR instruction in DDR sequence, all data bits last two serial root clock cycles on FlexSPI interface. Following diagram indicates the relationship of serial root clock, Data and SCK:

**Figure 26-24. SDR instruction in DDR sequence**

- **DDR instruction in DDR sequence**

In the case of DDR instruction in DDR sequence, all data bits last one serial root clock cycle on FlexSPI interface. Following diagram indicates the relationship of serial root clock, Data and SCK:

**Figure 26-25. DDR instruction in DDR sequence**

### 26.7.13.2 Output timing between Chip selection and SCK

This section describes the output timing relationship of Chip select (on PCSA1/PCSA2/PCSB1/PCSB2) and SCK. The timing relationship is a little different for SDR sequence and DDR sequence.

- **Chip Select timing in SDR sequence**

For SDR sequence, the delay from chip select assertion and the SCK rising edge is  $(FLSH \times CR1[TCSS] + 0.5)$  cycles of serial root clock; The delay from SCK falling edge and chip select deassertion is  $FLSH \times CR1[TCSH]$  cycles of serial root clock. Following diagram indicates the timing relationship between chip selection and SCK:

**Figure 26-26. Chip selection output timing for SDR sequence**

- **Chip Selection timing in DDR sequence**

For DDR sequence, the delay from chip selection assertion and SCK rise edge is **(TCSS+0.5)** cycles of serial root clock; The delay from SCK fall edge and chip selection deassertion is **(TCSH+0.5)** cycles of serial root clock. Following diagram indicates the timing relationship between chip selection and SCK:

**Figure 26-27. Chip selection output timing for DDR sequence**

For certain device (such as FPGA device), there is limitation on the interval between Chip Selection valid. FlexSPI will ensure a delay time between chip selection valid if register field `FLSHxCR1[CSINTERVAL]` is set to non-zero value. The delay time is:  $CSINTERVAL * 1024$  cycle of serial root clock no matter SDR or DDR sequence. Please set this register field value to zero if there is no this limitation for external device. Following diagram indicates the timing of chip selection interval.

**Figure 26-28. Chip Selection Valid interval**

## 26.7.14 FlexSPI Input Timing

This section describes the input timing of FlexSPI.

### 26.7.14.1 RX Clock Source Features

This section describes the features of each RX clock source.

- **Internal dummy read strobe and loopbacked internally(MCR0.RXCLKSRC==0)**

Supporting legacy device with zero device output hold time.

Saving one pad(DQS pad).

Supporting low frequency clock for boot up usage.

- **Internal dummy read strobe and loopbacked from DQS pad(MCR0.RXCLKSRC==1)**

Supporting higher frequency than mode "MCR0.RXCLKSRC==0".

Supporting device doesn't provide read strobe.

- **Flash provided read strobe(MCR0.RXCLKSRC==3)**

Supporting the highest frequency.

Supporting device provides read strobe.

### 26.7.14.2 Input timing for sampling with dummy read strobe

This section describes the input timing when sampling with internal dummy read strobe (MCR0[RX\_CLK\_SRC] is set to 0x0 or 0x1). The timing is very similar for sampling with dummy read strobe loopback internally and loopback from pad. But it could achieve higher read frequency by sampling with dummy read strobe loopback from DQS pad because it will compensate the delay of SCK output path and Data pin input path. The input timing is different for SDR mode and DDR mode.

- **Input timing for sampling with dummy read strobe in SDR mode**

For SDR Read/Learn instruction, FlexSPI samples input data pins with the falling edge of dummy read strobe. Following diagram indicates the input timing for sampling with dummy read strobe in SDR mode

**Figure 26-29. Input Timing for sampling with dummy read strobe in SDR mode**

- **Input timing for sampling with dummy read strobe in DDR mode**

For DDR Read/Learn instruction, FlexSPI sample input data pins with both rise and fall edge of dummy read strobe. Following diagram indicates the input timing for sampling with dummy read strobe in DDR mode

**Figure 26-30. Input Timing for sampling with dummy read strobe in DDR mode**

### 26.7.14.3 Input timing for sampling with flash provided read strobe

This section describes the input timing when sampling with flash provided read strobe (MCR0[RXCLKSRC] is set to 0x3). The input timing is different for SDR mode and DDR mode.

#### NOTE

There are no known devices that provide read strobe and support SDR mode operation.

There are two kinds of Flash provided read strobe:

- **Flash provide read strobe with SCK2**

For certain flash devices, it provide read strobe with SCK2 and provide read data with SCK. Then read strobe edge is on the center with valid data window. FlexSPI controller should sample read data with read strobe directly (DLL is bypassed), refer [DLL configuration for sampling](#) for more details. Following diagrams indicates the input timing for sampling with flash read strobe in SDR mode and DDR mode:

**Figure 26-31. Input Timing 1 for Flash provided read strobe in SDR mode**

**Figure 26-32. Input Timing 1 for Flash provided read strobe in DDR mode**

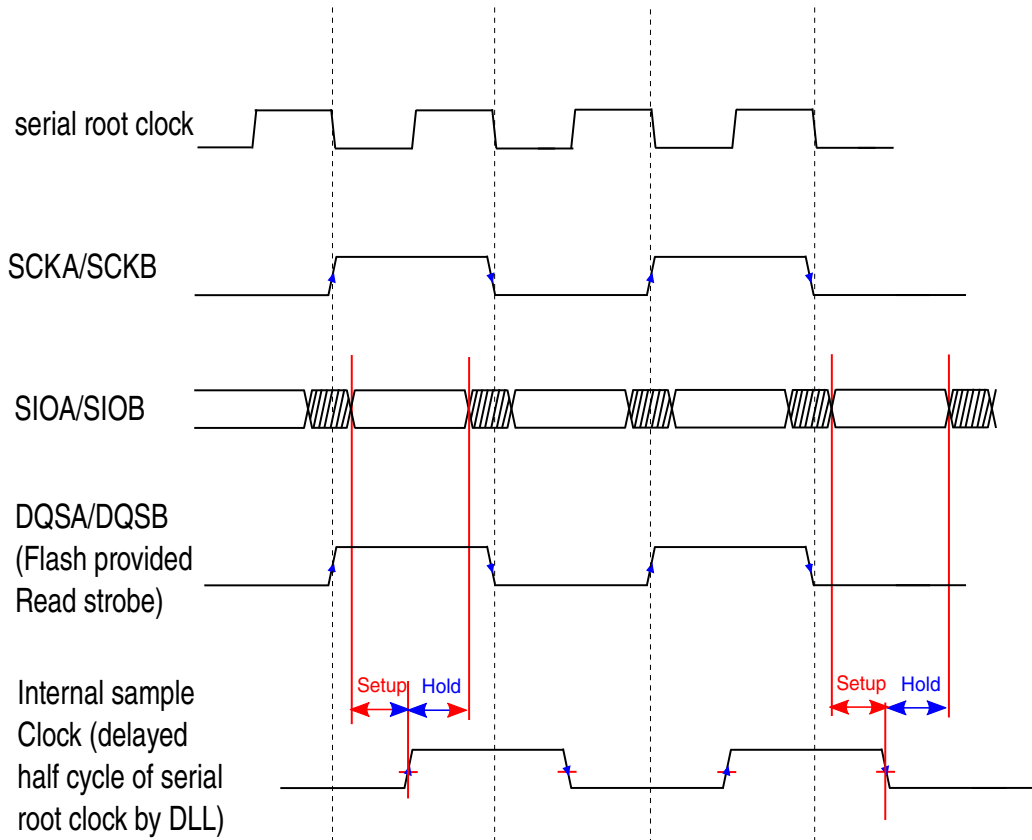

• **Flash provide read strobe with SCK**

For certain flash devices, it provides both read data and read strobes with SCK. Then the read strobe edge is aligned with read data change. FlexSPI controller should delay read strobe by half cycle in serial root clock (with DLL) and then sample read data with delayed strobe. Refer [DLL configuration for sampling](#) for more details. Following diagrams indicates the input timing for sampling with flash read strobe in SDR mode and DDR mode:

**Figure 26-33. Input Timing 2 for Flash provided read strobe in SDR mode**

**Figure 26-34. Input Timing 2 for Flash provided read strobe in DDR mode**

#### 26.7.14.4 DLL configuration for sampling

The input timing is different for those four sampling clock source. This is handled by setting register DLLxCR differently according to the sampling clock source mode. DLL is a delay line chain, which could be set to a fixed number of delay cells or auto-adjusted to lock on a certain phase delay to the reference clock.

- In following cases, DLLxCR should be set 0x00000100 (1 fixed delay cells in DLL delay chain) :
  - Sampling data with Dummy read strobe loopbacked internally(MCR0[RXCLKSRC]=0x0)
  - Sampling data with Dummy read strobe loopbacked from DQS pad(MCR0[RXCLKSRC]=0x1)
  - Sampling data with Flash provided read strobe (MCR0[RXCLKSRC]=0x3) and flash provides read strobe with SCK2
- When data is sampled with Flash provided read strobe (MCR0[RXCLKSRC]=0x3) and flash provides read strobe with SCK, DLL should be set as following to lock on half cycle of the reference clock (serial root clock)

- SLVDLYTARGET=0xF
- DLEN=0x1
- OVRDEN=0x0
- Other fields in DLLxCR should be kept as reset value (all zero)

### **NOTE**

If serial root clock is lower than 100 MHz, DLL is unable to lock on half cycle of serial root clock because the delay cell number is limited in delay chain. Then DLL should be configured as following instead:

- OVRDEN=0x1
- OVRDVAL=N; Each delay cell in DLL is about 75 ps~225 ps. The delay of DLL delay chain is (N \* Delay\_cell\_delay), N should be set based on max. DDR frequency that current project supported, N = 21, please notice this is a recommended value. May need to adjust in real application if facing failure.
- Other fields in DLLxCR should be kept as reset value (all zero).

## **26.7.15 Execute-In-Place Enhance mode**

FlexSPI always support Execute-In-Place no matter external device provided Execute-In-Place enhanced mode or not. Execute-In-Place is supported by putting program code on External device, then read/execute on external device directly by AHB read access to SFM space. There is no configuration or status polling needed during AHB read access to External device memory and AHB RX buffer is fully transparent to software.

Certain devices provide XIP enhanced mode to improve code execution (XIP). In this mode, there is no need to provide Command code for Read Sequence. It saves many cycles for Command Instructions and greatly improves code execution (XIP). This XIP enhanced mode is entered/exit by a special sequence which is device specified. Please refer to external device datasheet for more detail.

Normally, the XIP enhanced mode is entered by following sequence:

1. Enable XIP enhanced mode in External Flash by IP command
2. Send the first Read Sequence to External Flash device with correct Mode bits.  
Command code is needed in this Read sequence.
3. Send following Read sequences to External Flash device with correct Mode bits.  
Command code is not needed in these Read Sequences. But Mode bits should be sent

according to Flash specified. Otherwise Flash will exit Execute-In-Place Enhanced mode.

The instruction `JMP_ON_CS` in FlexSPI should be used to support external device XIP enhanced mode. This instruction is only allowed in AHB Read command, otherwise there will be `IPCMDERR` or `AHBCDMERR` error interrupt generated if this interrupt is enabled. `JMP_ON_CS` should never be used if device doesn't support XIP enhanced mode. To support XIP enhanced mode, the first instruction in the Read Sequence should be Command instruction and the last valid instruction should be `JMP_ON_CS` (with operand `0x1`).

For the first AHB read Command triggered, FlexSPI will execute the instructions from the instruction pointer 0 in the sequence (which is Command instruction). After this sequence executed FlexSPI will save operand in `JMP_ON_CS` instruction as start pointer for next Command to current device internally. For the following AHB read Command triggered, FlexSPI will execute from instruction pointer `0x1` and Command instruction is bypassed.

Following diagram indicates XIP operation with Flash XIP Enhanced mode:

**Figure 26-35. XIP Enhanced Mode operation**

## 26.8 Application information

This section describes applications supported by the FlexSPI module.

### 26.8.1 FlexSPI Initialization

FlexSPI controller initialization sequence is as following:

- Enable controller clocks (AHB clock/IP Bus clock/Serial root clock) in System level.
- Set `MCR0[MDIS]` to `0x1` (Make sure controller is configured in module stop mode)
- Configure module control registers: `MCR0`, `MCR1`, `MCR2`. (Don't change `MCR0[MDIS]`)
- Configure AHB bus control register (`AHBCR`) and AHB RX Buffer control registers (`AHBRXBUFxCR`) optionally if AHB command will be used

## Application information

- Configure Flash control registers (FLSHxCR0,FLSHxCR1,FLSHxCR2) according to external device type
- Configure DLL control register (DLLxCR) according to sample clock source selection
- set MCR0[MDIS] to 0x0 (Exit module stop mode)
- Configure LUT as needed (For AHB command or IP command)
- Reset controller optionally (by set MCR0[SWRESET] to 0x1)

External device needs configuration by IP command normally after controller initialization. For example, the device configuration is done by WRITE STATUS command for most serial NOR Flash.

## 26.8.2 Overview of Error Flags

The following table gives an overview of error category, flags and triggered source.

**Table 26-9. Error category and flags in FlexSPI**

Error Category	Triggered Source	Description	Error Flags
Command grant error	AHB write command	Command grant timeout	INTR[AHBCMDGE] will be set AHB bus error response
	AHB read command		INTR[AHBCMDGE] will be set AHB bus error response
	IP command		INTR[IPCMDGE] will be set
Command check error	AHB write comand	<ul style="list-style-type: none"> <li>• AHB write command with JMP_ON_CS instruction used in the sequence</li> <li>• There is unknown instruction opcode in the sequence.</li> <li>• Instruction DUMMY_SDR/ DUMMY_RWDS_SDR used in DDR sequence.</li> <li>• Instruction DUMMY_DDR/ DUMMY_RWDS_DDR used in SDR sequence.</li> </ul>	INTR[AHBCMDERR] will be set Command is not executed when error detected in command check
	AHB read command	<ul style="list-style-type: none"> <li>• There is unknown instruction opcode in the sequence.</li> <li>• Instruction DUMMY_SDR/ DUMMY_RWDS_SDR used in DDR sequence.</li> <li>• Instruction DUMMY_DDR/ DUMMY_RWDS_DDR used in SDR sequence.</li> </ul>	INTR[AHBCMDERR] will be set Command is not executed when error detected in command check

*Table continues on the next page...*

Table 26-9. Error category and flags in FlexSPI (continued)

Error Category	Triggered Source	Description	Error Flags
	IP command	<ul style="list-style-type: none"> <li>IP command with JMP_ON_CS instruction used in the sequence</li> <li>There is unknown instruction opcode in the sequence.</li> <li>Instruction DUMMY_SDR/ DUMMY_RWDS_SDR used in DDR sequence.</li> <li>Instruction DUMMY_DDR/ DUMMY_RWDS_DDR used in SDR sequence.</li> <li>Flash boundary across.</li> </ul>	<p>INTR[IPCMDERR] will be set</p> <p>Command is not executed when error detected in command check</p>
Command execution error	AHB write comand	Command timeout during execution	<p>INTR[AHBCMDERR] will be set</p> <p>INTR[SEQTIMEOUT] will be set</p> <p>There will be AHB bus error response except following case:</p> <ul style="list-style-type: none"> <li>AHB write comand is triggerd by flush (INCR burst ended with AHB_TX_BUF not empty)</li> <li>AHB bufferable write access and bufferable enabled (AHBCR[BUFFERABLEEN]=0x1)</li> </ul>
	AHB read command		<p>INTR[AHBCMDERR] will be set</p> <p>INTR[SEQTIMEOUT] will be set</p> <p>There will be AHB bus error response</p>
	IP command		<p>INTR[IPCMDERR] will be set</p> <p>INTR[SEQTIMEOUT] will be set</p>
AHB Bus timeout	AHB write command	AHB bus timeout (no bus ready return)	<p>INTR[AHBBUSTIMEOUT] will be set</p> <p>There will be AHB bus error response</p>
	AHB read command		

**NOTE**

- flash\_top\_address is the top address of currently accessed flash

**26.8.3 Application on Serial NOR Flash device**

This section provides the example sequences for serial NOR flash device (Spansion Flash S25FS128S).

**26.8.3.1 Write Enable command**

The following table shows WRITE ENABLE command sequence.

**Table 26-10. WRITE ENABLE command**

Instruction No.	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0x0	0x06	command name:WREN
1~7	STOP (0x00)	0x0	0x00	

**26.8.3.2 Write Registers command**

The following table shows Write Registers command sequence.

**Table 26-11. Write Registers command**

Instruction No.	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0x0 (Single)	0x01	command name:WRR
1	WRITE_SDR	0x0 (Single)	0x1 or 0x2	Data size is 1 or 2byte. Byte 0 write data for Status Register 1; Byte 1 write data for Configuration Register 1 This value could be overridden by IPCR1[IDATSZ].
2~7	STOP (0x00)	0x0	0x00	

### 26.8.3.3 Page Program command

The following table shows Page Program command sequence.

**Table 26-12. PAGE PROGRAM command (Spansion serial NOR flash)**

Instruction No.	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0x0 (Single)	0x02 or 0x12	command name: PP or 4PP PP is 3-Byte address mode. 4PP is 4-Byte address mode
1	ADDR_SDR	0x0 (Single)	0x18 or 0x20	Address bit number (operand value) should be 24 in 3-Byte address mode and 32 in 4-Byte address mode.
2	WRITE_SDR	0x0 (Single)	Any non-zero value	This operand value could be used as default programming data size if IPCR0.IDATSZ is zero. This value is ignored for AHB command.
3~7	STOP (0x00)	0x0	0x00	

The following table shows Page Program command sequence (QPI mode).

**Table 26-13. PAGE PROGRAM (QPI mode) command (Spansion serial NOR flash)**

Instruction No.	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0x2 (Quad)	0x02 or 0x12	command name: PP or 4PP PP is 3-Byte address mode. 4PP is 4-Byte address mode
1	ADDR_SDR	0x2 (Quad)	0x18 or 0x20	Address bit number (operand value) should be 24 in 3-Byte address mode and 32 in 4-Byte address mode.
2	WRITE_SDR	0x2 (Quad)	Any non-zero value	This operand value could be used as default programming data size if IPCR0.IDATSZ is zero. This value is ignored for AHB command.
3~7	STOP (0x00)	0x0	0x00	

### 26.8.3.4 Read Status 1 command

The following table shows READ STATUS 1 command sequence.

**Table 26-14. READ STATUS 1 command**

Instruction No.	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0x0 (Single)	0x05	command name:RDSR1
1	READ_SDR	0x0 (Single)	0x1	1 Byte for Status register 1
2~7	STOP (0x00)	0x0	0x00	

### 26.8.3.5 Read command

The following table shows READ command sequence.

**Table 26-15. READ command**

Instruction No.	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0x0 (Single)	0x03 or 0x13	command name:READ or 4READ READ is 3-Byte address mode. 4READ is 4-Byte address mode
1	ADDR_SDR	0x0 (Single)	0x18 or 0x20	Address bit number (operand value) should be 24 in 3-Byte address mode and 32 in 4-Byte address mode.
2	READ_SDR	0x0 (Single)	Any non-zero value	This operand value could be used as default reading data size if IPCR0.IDATSZ is zero. This value is ignored for AHB command.
3~7	STOP (0x00)	0x0	0x00	

### 26.8.3.6 Fast Read command

The following table shows Fast Read command sequence (In case of CR2V[7]=0, CR2V[3:0]=0x8).

**Table 26-16. FAST\_READ command**

Instruction No.	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0x0 (Single)	0x0B or 0x0C	command name:FAST_READ or 4FAST_READ FAST_READ is 3-Byte address mode. 4FAST_READ is 4-Byte address mode

*Table continues on the next page...*

**Table 26-16. FAST\_READ command (continued)**

Instruction No.	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
1	ADDR_SDR	0x0 (Single)	0x18 or 0x20	Address bit number (operand value) should be 24 in 3-Byte address mode and 32 in 4-Byte address mode.
2	DUMMY_SDR	0x0 (Single)	0x08	Dummy cycle is 8 (in serial root clock) as CR2V[3:0]=0x8.
3	READ_SDR	0x0 (Single)	Any non-zero value	This operand value could be used as default reading data size if IPCR0.IDATSZ is zero. This value is ignored for AHB command.
4~7	STOP (0x00)	0x0	0x00	

### 26.8.3.7 Dual IO Fast Read command

The following table shows Dual IO FAST\_READ command sequence (In case of CR2V[7]=0, CR2V[3:0]=0x8, Continuous Read mode).

**Table 26-17. Dual IO FAST\_READ command (Continuous Read mode)**

Instruction No.	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0x0 (Single)	0xBB or 0xBC	command name:DIOR or 4DIOR DIOR is 3-Byte address mode. 4DIOR is 4-Byte address mode
1	ADDR_SDR	0x1 (Dual)	0x18 or 0x20	Address bit number (operand value) should be 24 in 3-Byte address mode and 32 in 4-Byte address mode.
2	MODE8_SDR	0x1 (Dual)	0xAx	Enter continuous read mode or keep in continuous read mode.
3	DUMMY_SDR	0x1 (Dual)	0x08	Dummy cycle is 8 (in serial root clock) as CR2V[3:0]=0x8.
4	READ_SDR	0x1 (Dual)	Any non-zero value	This operand value could be used as default reading data size if IPCR0.IDATSZ is zero. This value is ignored for AHB command.
5	JMP_ON_CS	0x0 (or Dont care)	0x01	The CMD instruction will be bypassed after the first read access.
6~7	STOP (0x00)	0x0	0x00	

The following table shows Dual IO FAST\_READ command sequence (In case of CR2V[7]=0, CR2V[3:0]=0x8, Non-Continuous Read mode).

**Table 26-18. Dual IO FAST\_READ command (Non-Continuous Read mode)**

Instruction No.	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0x0 (Single)	0xBB or 0xBC	command name:DIOR or 4DIOR DIOR is 3-Byte address mode. 4DIOR is 4-Byte address mode
1	ADDR_SDR	0x1 (Dual)	0x18 or 0x20	Address bit number (operand value) should be 24 in 3-Byte address mode and 32 in 4-Byte address mode.
2	MODE8_SDR	0x1 (Dual)	Any value other than 0xAx	Exit continuous read mode or keep in non-continuous read mode.
3	DUMMY_SDR	0x1 (Dual)	0x08	Dummy cycle is 8 (in serial root clock) as CR2V[3:0]=0x8.
4	READ_SDR	0x1 (Dual)	Any non-zero value	This operand value could be used as default reading data size if IPCR0.IDATSZ is zero. This value is ignored for AHB command.
5~7	STOP (0x00)	0x0	0x00	

### 26.8.3.8 Quad IO Fast Read command

The following table shows Quad IO FAST\_READ command sequence (In case of CR2V[7]=0, CR2V[6]=0, CR2V[3:0]=0x8, Non-QPI mode, Non-Continuous read mode).

**Table 26-19. Quad IO FAST\_READ command (Non-QPI mode, Non-Continuous read mode)**

Instruction No.	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0x0 (Single)	0xEB or 0xEC	command name:QIOR or 4QIOR QIOR is 3-Byte address mode. 4QIOR is 4-Byte address mode
1	ADDR_SDR	0x2 (Quad)	0x18 or 0x20	Address bit number (operand value) should be 24 in 3-Byte address mode and 32 in 4-Byte address mode.
2	MODE8_SDR	0x2 (Quad)	Any value other than 0xAx	Exit continuous read mode or keep in non-continuous read mode.
3	DUMMY_SDR	0x2 (Quad)	0x08	Dummy cycle is 8 (in serial root clock) as CR2V[3:0]=0x8.
4	READ_SDR	0x2 (Quad)	Any non-zero value	This operand value could be used as default reading data size if IPCR0.IDATSZ is zero. This value is ignored for AHB command.
5~7	STOP (0x00)	0x0	0x00	

The following table shows Quad IO FAST\_READ command sequence (In case of CR2V[7]=0, CR2V[6]=0, CR2V[3:0]=0x8, Non-QPI mode, Continuous read mode).

**Table 26-20. Quad IO FAST\_READ command (Non-QPI mode, Continuous read mode)**

Instruction No.	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0x0 (Single)	0xEB or 0xEC	command name:QIOR or 4QIOR QIOR is 3-Byte address mode. 4QIOR is 4-Byte address mode
1	ADDR_SDR	0x2 (Quad)	0x18 or 0x20	Address bit number (operand value) should be 24 in 3-Byte address mode and 32 in 4-Byte address mode.
2	MODE8_SDR	0x2 (Quad)	0xA0	Enter continuous read mode or keep in continuous read mode.
3	DUMMY_SDR	0x2 (Quad)	0x08	Dummy cycle is 8 (in serial root clock) as CR2V[3:0]=0x8.
4	READ_SDR	0x2 (Quad)	Any non-zero value	This operand value could be used as default reading data size if IPCR0.IDATSZ is zero. This value is ignored for AHB command.
5	JMP_ON_CS	0x0 (or Dont care)	0x01	The CMD instruction will be bypassed after the first read access.
6~7	STOP (0x00)	0x0	0x00	

The following table shows Quad IO FAST\_READ command sequence (In case of CR2V[7]=0, CR2V[6]=1, CR2V[3:0]=0x8, QPI mode, Continuous read mode).

**Table 26-21. Quad IO FAST\_READ command (QPI mode, Continuous read mode)**

Instruction No.	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0x2 (Quad)	0xEB or 0xEC	command name:QIOR or 4QIOR QIOR is 3-Byte address mode. 4QIOR is 4-Byte address mode
1	ADDR_SDR	0x2 (Quad)	0x18 or 0x20	Address bit number (operand value) should be 24 in 3-Byte address mode and 32 in 4-Byte address mode.
2	MODE8_SDR	0x2 (Quad)	0xA0	Enter continuous read mode or keep in continuous read mode.
3	DUMMY_SDR	0x2 (Quad)	0x08	Dummy cycle is 8 (in serial root clock) as CR2V[3:0]=0x8.
4	READ_SDR	0x2 (Quad)	Any non-zero value	This operand value could be used as default reading data size if IPCR0.IDATSZ is zero. This value is ignored for AHB command.
5	JMP_ON_CS	0x0 (or Dont care)	0x01	The CMD instruction will be bypassed after the first read access.
6~7	STOP (0x00)	0x0	0x00	

### 26.8.3.9 DDR Quad IO Fast Read command

The following table shows DDR Quad IO FAST\_READ command sequence (In case of CR2V[7]=0, CR2V[6]=0, CR2V[3:0]=0x8, Non-QPI mode, Non-Continuous read mode).

**Table 26-22. DDR Quad IO FAST\_READ command (Non-QPI mode, Non-Continuous read mode)**

Instruction No.	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0x0 (Single)	0xED or 0xEE	command name:QIOR_DDR or 4QIOR_DDR QIOR_DDR is 3-Byte address mode. 4QIOR_DDR is 4-Byte address mode
1	ADDR_DDR	0x2 (Quad)	0x18 or 0x20	Address bit number (operand value) should be 24 in 3-Byte address mode and 32 in 4-Byte address mode.
2	MODE8_DDR	0x2 (Quad)	Any value other than 0xAx	Exit continuous read mode or keep in non-continuous read mode.
3	DUMMY_DDR	0x2 (Quad)	0x08	Dummy cycle is 8 (in serial root clock) as CR2V[3:0]=0x8.
4	LEARN_DDR	0x2 (Quad)	0x1	DLP (Data Learning Pattern is 8 bits).
5	READ_DDR	0x2 (Quad)	Any non-zero value	This operand value could be used as default reading data size if IPCR0.IDATSZ is zero. This value is ignored for AHB command.
6~7	STOP (0x00)	0x0	0x00	

The following table shows DDR Quad IO FAST\_READ command sequence (In case of CR2V[7]=0, CR2V[6]=0, CR2V[3:0]=0x8, Non-QPI mode, Continuous read mode).

### 26.8.4.2 HyperRAM

This section provides the example sequences for HyperRAM (Cypress S27KL series).

Read (memory) command sequence is same as HyperFlash. The following table shows Write (memory) command sequence.

**Table 26-29. Write (memory) command**

Instruction No.	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_DDR	0x3 (Octal)	0x20	CA bit 47: (R/W#) = 0x0 CA bit 46: (Target) = 0x0 CA bit 45: (Burst Type) = 0x1 CA bit 44-40: All reserved = 0x0
1	RADDR_DDR	0x3 (Octal)	0x18	Row Address: 24 bits

*Table continues on the next page...*

**Table 26-29. Write (memory) command (continued)**

Instruction No.	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
2	CADDR_DDR	0x3 (Octal)	0x10	Column Address: (13 zero bits + 3 valid bits)
3	DUMMY_RWDS_DR	0x3 (Octal)	0x0B	In case of latency count=11
4	WRITE_DDR	0x3 (Octal)	Any non-zero value	This operand value could be used as default write data size if IPCR0.IDATSZ is zero. This value is ignored for AHB command.
5~7	STOP (0x00)	0x0	0x00	

## 26.8.5 Application on Serial NAND Flash device

This section provides the example sequences for serial NAND flash device (Micron Flash MT29 series). The operation to serial NAND flash is quite similar to serial NOR flash.

READ operation sequence is as following:

- Page Read (Transfer the data from the NAND Flash array to the cache register)
- Get Feature to read the status
- Random Data Read

The following table shows Page Read command sequence.

**Table 26-30. Page Read command**

Instruction No.	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0x1 (Single)	0x13	Command code: 0x13
1	RADDR_SDR	0x1 (Single)	0x18	Row Address: 24 bit
2-7	STOP (0x0)	0x0	0x00	

The following table shows Get Feature command sequence.

**Table 26-31. Get Feature command**

Instruction No.	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0x1 (Single)	0x0F	Command code: 0x0F
1	CMD_SDR	0x1 (Single)	0xC0	Status register address (0xC0)
2	READ_SDR	0x1 (Single)	0x02	2 Byte read data
3-7	STOP (0x0)	0x0	0x00	

The following table shows Random Data Read command sequence.

**Table 26-32. Read From Cache x4 command**

Instruction No.	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0x1 (Single)	0x6B	Command code: 0x6B
1	MODE4_SDR	0x1 (Single)	0x0 or 0x1	Software should decode the flash address and set mode bits as 0x1 if plane selection is one, or 0x0 if plane selection is zero.  Plane selection bit is the 18th bit of flash address. If NAND flash size is less than 4Gbit, plane selection will always be zero.
2	CADDR_SDR	0x1 (Single)	0x0C	Column address: 12 bit
3	DUMMY_SDR	0x2 (Quad)	0x08	Dummy cycle number: 8 (serial root clock)
4	READ_SDR	0x2 (Quad)	Any non-zero value	This operand value could be used as default reading data size if IPCR0.IDATSZ is zero.
5-7	STOP (0x0)	0x0	0x00	

Program operation sequence is as following:

- Write Enable
- Program Load (Transfer the write data to the cache register)
- Program Execute
- Get Feature to read the status

The following table shows Program Load command sequence.

**Table 26-33. Program Load command**

Instruction No.	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0x1 (Single)	0x02	Command code: 0x02
1	MODE4_SDR	0x1 (Single)	0x0 or 0x1	Software should decode the flash address and set mode bits as 0x1 if plane selection is one, or 0x0 if plane selection is zero.  Plane selection bit is the 18th bit of flash address. If NAND flash size is less than 4Gbit, plane selection will always be zero.
2	CADDR_SDR	0x1 (Single)	0x0C	Column address: 12 bit
3	WRITE_SDR	0x1 (Single)	Any non-zero value	This operand value could be used as default write data size if IPCR0.IDATSZ is zero.
4-7	STOP (0x0)	0x0	0x00	

The following table shows Program Execute command sequence.

**Table 26-34. Program Execute command**

Instruction No.	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0x1 (Single)	0x10	Command code: 0x10
1	RADDR_SDR	0x1 (Single)	0x18	Row Address: 24 bit
2-7	STOP (0x0)	0x0	0x00	

## 26.8.6 Application on FPGA device

FPGA device should be accessed by AHB command. All AHB accesses to FPGA will be transparent to SW driver (no SW intervention). There may be some special requirements from FPGA device.

### 1. Device type may be different on A1/A2/B1/B2

For this case, clear the MCR2[SAMEDEVICEEN] bit and configure FLSHxCR0 and FLSHxCR1 register separately for up to four external devices.

### 2. Device needs different wait cycle for Programming.

The AHB write wait cycle number could be set separately for these four external devices (by register field FLSHxCR2[AWRWAIT]). Software could configure the sequences in LUT with different DUMMY instructions (operand will determine dummy cycle). Note that FlexSPI will hold AHB bus ready for this wait time, so AHB Bus performance may become very low when this wait time is very long.

### 3. Device needs different wait cycle for Reading.

The AHB Read Sequence index and Sequence Number could be set separately for these four external devices (by register field FLSHxCR2[ARDSEQID] and FLSHxCR2[ARDSEQNUM]). Software could configure the sequences in LUT with different DUMMY instruction (operand will determine dummy cycle).

### 4. Device may be sensitive to read instruction clock cycle number

Device will be sensitive to read instruction clock cycle number if its internal memory is implemented similar as FIFO. For this case, software could send the data size information to external device by DATSZ instruction. FPGA device should decode the data size information and determine how much data bytes should be popped.

### 5. Device may needs interval time between Chip selection valid

This could be handled by register field `FLSHxCR2[CSINTERVAL]` setting.

#### **6. Device may use SCK as reference clock for its internal PLL**

In this case, SCK should be free-running and clock frequency should be stable. This could be achieved by setting `MCR0[SCKFREERUN_EN]` and use SDR sequence only.

### 27.2 ARM Cortex M7 Platform

#### 27.2.1 Overview

The Cortex-M7 platform features a single ARM®Cortex®-M7 processor in this chip. The ARM®Cortex®-M7 processor is a highly efficient, high-performance, embedded processor that features low interrupt latency, low-cost debug, and has backwards compatibility with existing Cortex-M profile processors. The processor has an in-order super-scalar pipeline by which many instructions can be dual-issued, including load/load and load/store instruction pairs because of multiple memory interfaces.

Memory interfaces that the processor supports include:

- Tightly-Coupled Memory (TCM)

- Harvard instruction and data caches and AXI master (AXIM) interface
- Dedicated low-latency AHB-Lite peripheral (AHBP) interface

The ARM Cortex-M7 Platform supports the following:

- 32 KB L1 Instruction Cache
- 32 KB L1 Data Cache
- Floating Point Unit (FPU) with support for the FPv5 architecture
- Internal Trace (TRC)

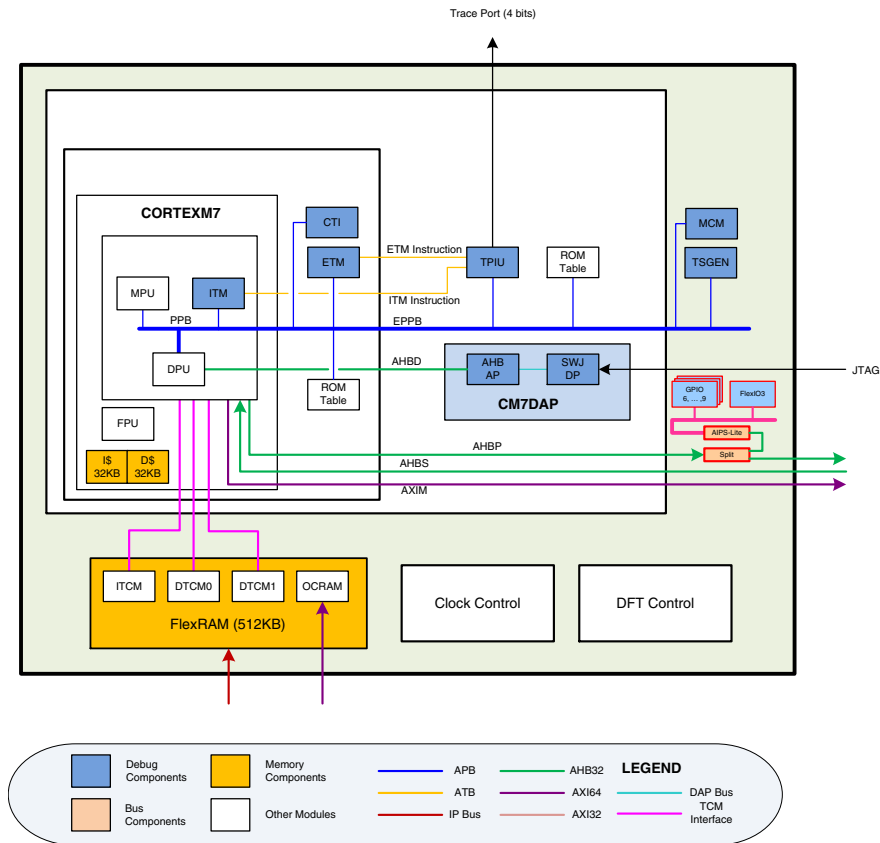

The number of IRQs supported for this chip is 160. In addition, it supports various components composing the ARM CoreSight debug/Trace system, such as ETM and CTI.

**NOTE**

This chip supports up to 16 interrupt priority levels, i.e. it implements bits [7:4] of each NVIC Interrupt Priority Register.

**27.2.2 Block Diagram**

A block diagram for the Cortex-M7 is given below:

**Figure 27-1. Cortex-M7 Platform Block Diagram**

Interrupts, DMA Events and XBAR Assignments	-	<a href="#">Interrupts, DMA Events and XBAR Assignments</a>

### 28.2 Overview

This section provides an overview of the

- NIC-301 (Network Inter-Connect) AXI arbiter IP

The NIC-301 (by ARM Ltd.) is a configurable AXI arbiter between several masters and slaves. The NIC-301 IP is designed so that many configuration options are selected at the hardware design stage, determined by SoC characteristics and needs, while several other configuration options are software-controlled.

This chapter covers in brief the NIC-301 while providing configuration details on the NIC-301 instances used in the chip. For complete details on the NIC-301 design, see the ARM specification, *AMBA® Network Interconnect (NIC-301) Technical Reference Manual, version r2p3*.

## NOTE

The NIC-301 default settings are configured by NXP's board support package (BSP), and in most cases should not be modified by the customer. The default settings have gone through exhaustive testing during the validation of the part, and have proven to work well for the part's intended target applications. Changes to the default settings may result in a degradation in system performance.

### 28.2.1 NIC-301 Main Features

Key features of the NIC-301 module include the following:

- Address space memory mapping.
- Programmer's view, for software-configured parameters, via internal "GPV" ports.
- Support for cross-clock domain synchronization.

### 28.2.2 Modes and Operations

The NIC-301 supports a normal functional mode only.

## 28.3 External Signals

There are no external I/O interfaces for NIC-301.

## 28.4 Memory Map and Register Definition

The bus system is composed of five instances: SIM\_M7, SIM\_PER, SIM\_M, SIM\_MAIN and SIM\_EMS. Three of them have GPV registers which are helpful for bus arbitration and performance. For detailed descriptions of these registers, see the ARM document: *DDI0397I\_corelink\_network\_interconnect\_nic301\_r2p3\_trm.pdf*.

### 1. SIM\_MAIN registers

The SIM\_MAIN GPV base address is `GPV0_BASE = 0x41000000`. The following registers are implemented in this NIC.

Register Name	Port Name	Module Name	Absolute Address	Reset Value	Descriptions
read_qos	m_a_2	LCD	GPV0_BASE + 0x44000 + 0x100	1	Set the priority of master's read. The priority level would be used when the master's read transaction is being arbitrated by the NIC.  Legal programmable values are from 0 to 15. Higher number sets higher priority (0: the lowest arbitration priority; ...; 15: the highest priority).
read_qos	m_a_3	CSI	GPV0_BASE + 0x45000 + 0x100	4	Same as above
read_qos	m_a_4	PXP	GPV0_BASE + 0x46000 + 0x100	2	Same as above
write_qos	m_a_2	LCD	GPV0_BASE + 0x44000 + 0x104	1	Set the priority of master's write. The priority level would be used when the master's write transaction is being arbitrated by the NIC.  Legal programmable values are from 0 to 15. Higher number sets higher priority (0: the lowest arbitration priority; ...; 15: the highest priority).
write_qos	m_a_3	CSI	GPV0_BASE + 0x45000 + 0x104	4	Same as above
write_qos	m_a_4	PXP	GPV0_BASE + 0x46000 + 0x104	2	Same as above
fn_mod	m_a_2	LCD	GPV0_BASE + 0x44000 + 0x108	0	Issuing functionality modification register. This register sets the block issuing capability to one outstanding transaction.  Legal programmable values are 0, 1, 2 and 3.

*Table continues on the next page...*

## Memory Map and Register Definition

Signal multiplexing	IOMUX	<a href="#">External Signals and Pin Multiplexing</a> <a href="#">IOMUX</a>
Interrupts, DMA Events and XBAR Assignments	-	<a href="#">Interrupts, DMA Events and XBAR Assignments</a>

### 29.2 Overview

There is 1 OCRAM controller implemented in the chip. One controller is for up to 512 KB on-chip RAM. The size of OCRAM is configured in the FlexRAM module via IOMUXC. For more details, refer to the FlexRAM chapter.

The on-chip RAM block is implemented as a slave module on the 64-bit system AXI bus. Designed as a simple on-chip memory controller, it supports only one AXI port with memory banks. For the AXI port, the read and write transactions are handled by two independent modules. As it is possible to have simultaneous read and write request from the AXI bus, each memory bank has an arbiter with round-robin scheme. After arbitration, the granted read or write access command can then be issued to the memory cell through a read/write MUX.

## Basic Functions

The memory banks are organized with the lower 2 bits of the address which is the AXI bus address and is 64 bits aligned interleaved. This allows a read access and a write access to be processed at the same time if they are targeted to different memory banks.

Various options are provided for adding a pipeline or wait-states in a read/write access, in order to ensure flexible timing control at both high and low frequencies.

The internal block diagram is shown in the figure below.

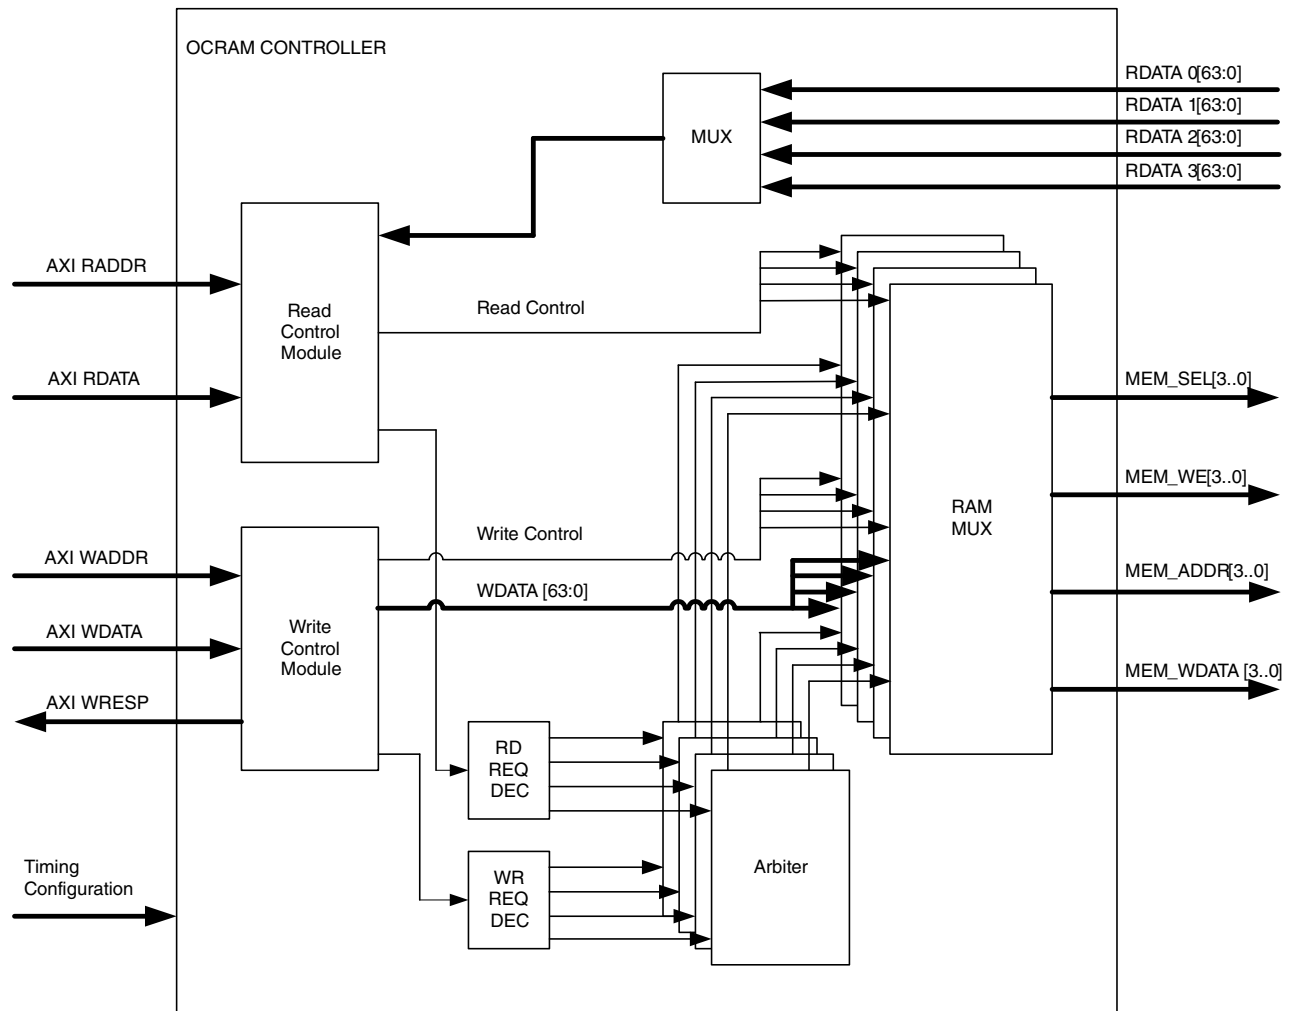

Figure 29-1. On-chip RAM Block Diagram

## 29.3 Basic Functions

### 29.3.1 Read/Write Arbitration

The detailed rules used in arbitration are as follows:

- If there is no granted read or write in the last cycle, and there is only a read request or a write request, the request will be granted.
- If there is no granted read or write in the last cycle, and there are both read or write requests coming in at the same time, the read request will be granted first.
- If a granted read/write transaction has just finished, the write/read request will have the higher priority in the next cycle.
- If the first read/write access request in a transaction is granted, all the data transfer in this burst will be finished before the next arbitration begins, that is, the round-robin arbitration mechanism is based on AXI transaction, not data access.

## 29.4 Advanced Features

This section describes some advanced features designed to avoid timing issues when the on-chip RAM is working at high frequency.

All of the features can be disabled/enabled by programming the corresponding fields of the General Purpose Register (IOMUXC.GPR3) bits [3:0] in the IOMUX chapter.

### 29.4.1 Read Data Wait State

When the wait state is enabled, it will take 2 cycles for each read access (each beat of a read burst).

This can avoid the potential timing problem caused by the longer memory access time at higher frequency.

When this feature is disabled, it only takes 1 clock cycle to finish a read transaction. That is, read data is available in the next cycle of read request becomes valid on the bus.

For the normal OCRAM, the read data wait state is configurable via IOMUXC.GPR3[0].

### 29.4.2 Read Address Pipeline

When this feature is enabled, the read address from the AXI master is delayed 1 cycle before it can be accepted by the on-chip RAM.

This can avoid setup time issues for the read access on the memory cell at high frequency. Enabling this feature can cost, at most, 1 more clock cycle for each AXI read transaction, that is, at most 1 more clock cycle for each read burst with multiple beats of data.

When this feature is disabled, the read address from the AXI master can be accepted by the on-chip RAM without delay, and data can become ready for master at next clock cycle (if no other access and no read data wait).

For the normal OCRAM, the read address pipeline is configurable via IOMUXC.GPR3[1].

### 29.4.3 Write Data Pipeline

When this feature is enabled, the write data from the AXI master would be delayed 1 cycle before it can be accepted by the on-chip RAM.

This can avoid setup time issue for the write access on the memory cell at high frequency. Enabling this feature would cost at most 1 more clock cycle for each AXI write transaction, that is, at most 1 more clock cycle for each write burst with multiple beats of data.

When this feature is disabled, the write data from the AXI master can be accepted by the on-chip RAM without delay, and data can be written to memory at this cycle (if no other access and write address is also ready at this cycle).

For the normal OCRAM, the write data pipeline is configurable via IOMUXC.GPR3[2].

### 29.4.4 Write Address Pipeline

When this feature is enabled, the write address from the AXI master would be delayed 1 cycle before it can be accepted by the on-chip RAM.

This can avoid setup time issue for the write access on the memory cell at high frequency. Enabling this feature would take at most 1 more clock cycle for each AXI write transaction, that is, at most 1 more clock cycle for each write burst with multiple beats of data.

When this feature is disabled, the write address from the AXI master can be accepted by the on-chip RAM without delay, and data can be written to memory at this cycle (if no other access and write data is also ready at this cycle).

For the normal OCRAM, the write address pipeline is configurable via IOMUXC.GPR3[3]

## 29.5 Programmable Registers

There are no programmable registers in this block; however, OCRAM configurable bits can be found in the IOMUX Controller (IOMUXC) general purpose registers found here.

- TrustZone bits: IOMUXC\_GPR10
- WAIT state / Pipeline bits: IOMUXC\_GPR3

Interrupts, DMA Events and XBAR Assignments	-	<a href="#">Interrupts, DMA Events and XBAR Assignments</a>

### 30.2 Overview

#### 30.2.1 Introduction

This SoC has 512 KB of on-chip RAM which is shared by I-TCM, D-TCM and general purpose On Chip RAM (OCRAM). The FlexRAM is the manager of the big on-chip RAM array.

#### 30.2.2 Features

The FLEXRAM includes the following features:

- Integrated I-TCM and D-TCM RAM controller

- 64-bit I-TCM interface and 2x 32-bit D-TCM interface.
- The controller supports up to 512 KB TCM (for both ITCM and DTCM) space.
- The controller supports two access modes:
  - Fast mode: RAM accesses is expected to be finished in 1-cycle for both read and write.
  - Wait mode: RAM accesses is expected to be finished in 2-cycle. Wait mode for read and write path can be enabled separately.
- Synchronous interface to the M7 Core,run at the same frequency as the core
- Automatically clock gating control to reduce power consumption
- Integrated OCRAM controller
  - single SRAM bank controller.
  - support up to 512 KB SRAM size
  - Synchronous to the system bus, runs at the same frequency as bus fabric
- Parameterized RAM Array
  - Support up to 512 KB total memory space
  - Support up to 32 block of 32-bit RAM
- RAM Array portioning
  - RAM size of ITCM, DTCM and OCRAM can be configured from 0 to full RAM Array size separately
  - Step of the RAM size partitioning for ITCM, DTCM and OCRAM is (Total RAM SIZE)/16
  - Flexible RAM bank organization.
- Flexible power mode:
  - Run mode: All RAM banks are powered on
  - Retention mode: Only 1 (Bank0) out of the 16 RAM banks is on while the rest banks are powered off
  - Partial mode: 8 out of the 16 RAM banks (bank8 to bank15) can be powered off dynamically
- Bank8~15 can be disabled with hardware fuse setting. When the fuse is set, total RAM size will be limit to 256 KB
- Generates interrupt upon TCM, OCRAM access out of configured RAM range

### 30.2.3 Block diagram

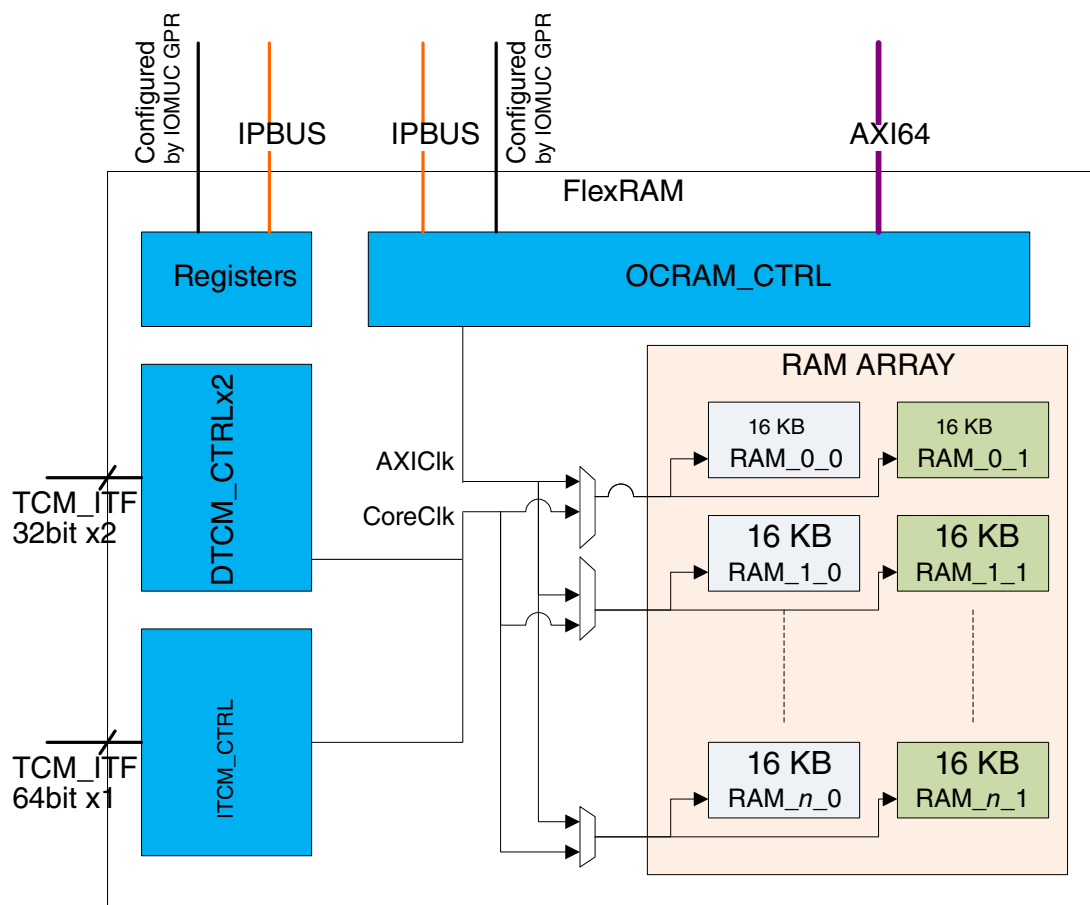

Figure 30-1. FLEXRAM block diagram

## 30.3 Functional description

FLEXRAM converts AXI and TCM interface signals to RAM interface signals and implements mux control for OGRAM, DTCM and ITCM access to on-chip RAM.

### 30.3.1 Interface Conversion

FLEXRAM integrate OGRAM controller which converts AXI master interface signals to RAM interface signals (Please see OGRAM section). OGRAM controller can support to add pipeline or wait-state in read/write access by IOMUX GPR.

## Functional description

FLEXRAM also implement TCM controller module to convert DTCM/ITCM interface to RAM interface. TCM read/write access can be extended to 2 cycles by setting TCM\_CTRL register. When DTCM and ITCM access unallocated RAM address, TCM controller can send tcm\_err to DTCM/ITCM interface.

### 30.3.2 RAM Bank Allocation

OCRAM, DTCM and ITCM share 512 KB of on-chip RAM. SW can configure from 0 to 512 KB full RAM array size for OCRAM, DTCM and ITCM by IOMUX GPR16 and GPR17. The RAM size step is 32KB. The allocated RAM bank can be not overlapped for OCRAM, DTCM and ITCM. Table below show an example of a 128KB ITCM, 128KB DTCM and 256KB OCRAM configuration.

**Table 30-2. FLEXRAM Partitioning Example**

	ITCM	DTCM	OCRAM
Bank0	0	0	1
Bank1	0	0	1
Bank2	0	0	1
Bank3	0	0	1
Bank4	1	0	0
Bank5	1	0	0
Bank6	0	1	0
Bank7	0	1	0
Bank8	0	0	1
Bank9	0	0	1
Bank10	0	0	1
Bank11	0	0	1
Bank12	1	0	0
Bank13	1	0	0
Bank14	0	1	0
Bank15	0	1	0

Each RAM bank has 2 bits bank configuration from IOMUX GPR17.

**Table 30-3. RAM Bank configuration**

	RAM Bank Configuration
00	Not used
01	OCRAM
10	DTCM
11	ITCM

### 30.3.3 Low power modes

FLEXRAM has input fuse control signal to control ocram bank8~bank15 interface access. When the fuse bit is programmed, bank8~bank15 can't be accessed again and can be power down.

### 30.3.4 Clocks

The following table describes the clock sources of the FlexRAM module.

**Table 30-4. FlexRAM Clocks**

Clock name	Clock Root	Description
ipg_clk	ipg_clk_root	Peripheral clock
ipg_clk_s	ipg_clk_root	Peripheral access clock for register accesses

### 30.3.5 Reset

FLAMRAM has 2 reset signals. One is used for OCRAM interface and in always on power domain. The other is used for TCM interface and in core power domain.

### 30.3.6 Interrupts

FLEXRAM can generate interrupt in the following cases:

- OCRAM, DTCM or ITCM access the RAM address which is not allocated.

## 30.4 Memory Map and register definition

This section includes the FLEXRAM module memory map and detailed descriptions of all registers.

## 30.4.1 FLEXRAM register descriptions

### 30.4.1.1 FLEXRAM Memory map

FlexRAM base address: 400B\_0000h

Offset	Register	Width (In bits)	Access	Reset value

# Chapter 31

## AHB to IP Bridge (AIPSTZ)

### 31.1 Chip-specific AIPSTZ information

Table 31-1. Reference links to related information

Topic	Related module(s)	Reference
System memory map	-	<a href="#">System Memory Map</a>
Clocking	CCM	<a href="#">Clock Management</a> <a href="#">Clock Control Module (CCM)</a>
Power management	PMU	<a href="#">Power Management</a> <a href="#">Power Management Unit</a>

### 31.2 Overview

This section provides an overview of the AHB to IP Bridge (AIPSTZ). This particular peripheral is designed as the bridge between AHB bus and peripherals with the lower bandwidth IP Slave (IPS) buses.

#### 31.2.1 Features

The following list summarizes the key features of the bridge:

- The bridge supports the IPS slave bus signals. This interface is only meant for slave peripherals.
- The bridge supports 8-, 16-, and 32-bit IPS peripherals. (Accesses larger than the size of a peripheral are not supported, except to 32-bit memory.)
- The bridge supports a pair of IPS accesses for 64-bit and certain misaligned AHB transfers to 32-bit memory in 64-bit platforms.
- The bridge directly supports up to 32 16-Kbyte external IPS peripherals, and 2 global external IPS peripheral spaces. The bridge occupies 1 MBytes of total address space.

- The bridge provides configurable per-block and per-master access protections. Access permissions are based on bus master (e.g. DMA or core) privilege levels and resource domain. More details on the protection features and configuration can be found in the Security Reference Manual
- Peripheral read transactions require a minimum of 2 hclk clocks, and unbuffered write transactions require a minimum of 3 hclk clocks.
- The bridge uses one single asynchronous reset and one global clock.

### 31.3 Clocks

The following table describes the clock sources for AIPSTZ. Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information.

**Table 31-2. AIPSTZ Clocks**

Clock name	Clock Root	Description
hclk	ahb_clk_root	Module clock

### 31.4 Functional Description

The AIPS bridge serves as a protocol translator between the AHB system bus and the IP bus.

Support is provided for generating a pair of 32-bit IP bus accesses when targeted by a 64-bit system bus access, or a misaligned access which crosses a 32-bit boundary. No other bus-sizing access support is provided.

The AHB to IP bridge is the interface between the AHB and on-chip IPS peripherals, which are sub-blocks containing readable/writable control and status registers.

The AHB master reads and writes these registers through the AIPSTZ. The bridge generates block enables, the block address, transfer attributes, byte enables and write data as inputs to the IPS peripherals. The bridge captures read data from the IPS interface and drives it on the AHB.

Each bridge that connects to the IPS (or peripherals) are referred as AIPS. The chip has three separate AIPS modules, and peripherals are grouped and assigned under each AIPS block. The list of peripherals are indicated as n-1, n-2, and n-3 for AIPS-1, AIPS-2, and AIPS-3 respectively.

AIPS occupies a 1-Mbyte portion of the address space. The register maps of the IPS peripherals are located on 16-Kbyte boundaries. Each IPS peripheral is allocated one 16-Kbyte block of the memory map, and is activated by one of the block enables from the bridge. Up to thirty-two 16-Kbyte external IPS peripherals may be implemented, occupying contiguous blocks of 16-Kbytes. Two global external IPS block enables are available for the remaining address space to allow for customization and expansion of addressed peripheral devices. In addition, a single "non-global" block enable is also asserted whenever any of the thirty-two non-global block enables is asserted.

The bridge is responsible for indicating to IPS peripherals if an access is in supervisor or user mode. It may block user mode accesses to certain IPS peripherals or it may allow the individual IPS peripherals to determine if user mode accesses are allowed. In addition, peripherals may be designated as write-protected.

The bridge supports the notion of "trusted" masters for security purposes. Masters may be individually designated as trusted for reads, trusted for writes, or trusted for both reads and writes, as well as being forced to look as though all accesses from a master are in user-mode privilege level. Refer to [AIPSTZ Memory Map/Register Definition](#) for more information.

The AIPSTZ prevents access to a peripheral if the transaction originated from a source from a resource domain that has been explicitly omitted. Resource domains are assigned in the RDC submodule. Please refer to the RDC chapter for programming details.

All peripheral devices are expected to only require aligned accesses equal to or smaller in size than the peripheral size. An exception to this rule is supported for 32-bit peripherals to allow memory to be placed on the IPS.

## 31.5 Access Protections

The AIPSTZ bridge provides programmable access protections for both masters and peripherals. It allows the privilege level of a master to be overridden, forcing it to user-mode privilege, and allows masters to be designated as trusted or untrusted.

Peripherals may require supervisor privilege level for access, may restrict access to a trusted master only, and may be write-protected. IP bus peripherals are subject to access control policies set in both CSU registers and AIPSTZ registers. An access is blocked if it is denied by either policy.

Masters and peripherals are assigned to one or more resource domains in the RDC submodule (see the RDC chapter for details). Depending on RDC programming, masters transactions through the AIPSTZ may or may not be allowed access to peripherals in different resource domains.

## 31.6 Access Support

Aligned 64-bit accesses, aligned and misaligned word and half word accesses, as well as byte accesses are supported for 32-bit peripherals. Misaligned accesses are supported to allow memory to be placed on the IPS.

Peripheral registers must not be misaligned, although no explicit checking is performed by the AIPS bridge. The bridge will perform two IPS transfers for 64-bit accesses, word accesses with byte offsets of 1, 2, or 3, and for half word accesses with a byte offset of 3. All other accesses will be performed with a single IPS transfer.

Only aligned half word and byte accesses are supported for 16-bit peripherals. All other accesses types are unsupported, and results of such accesses are undefined. They are not terminated with an error response.

Only byte accesses are supported for 8-bit peripherals. All other accesses types are unsupported, and results of such accesses are undefined. They are not terminated with an error response.

## 31.7 Initialization Information

The AIPS bridge should be programmed before use.

The following registers should be initialized: The Master Privilege Registers (AIPSTZ\_MPRs), the Peripheral Access Control registers (AIPSTZ\_PACRs), and the Off-platform Peripheral Access Control registers (AIPSTZ\_OPACRs) described in [AIPSTZ Memory Map/Register Definition](#).

### 31.7.1 Security Block

The AIPSTZ contains a security block that is connected to each off-platform peripheral. This block filters accesses based on write/read, non-secure, and supervisor signals.

Each peripheral can be individually configured to allow or deny each of the following transactions as described in the table below:

**Table 31-3. Peripheral Access Configuration options**

Config Bit	Write	Non-Secure	Supervisor	Meaning
0	0	0	0	Secure User Read

*Table continues on the next page...*

**Table 31-3. Peripheral Access Configuration options (continued)**

Config Bit	Write	Non-Secure	Supervisor	Meaning
1	0	0	1	Secure Supervisor Read
2	0	1	0	Non-Secure User Read
3	0	1	1	Non-Secure Supervisor Read
4	1	0	0	Secure User Write
5	1	0	1	Secure Supervisor Write
6	1	1	0	Non-Secure User Write
7	1	1	1	Non-Secure Supervisor Write

Each peripheral has a security configuration (`sec_config_X`) input for determining whether to allow or deny a given access type. These are 8-bit vectors, with each bit corresponding to one of the transactions above as listed in the Config Bit column of [Table 31-3](#). If the bit is asserted (1'b1), the transaction is allowed. If the bit is negated (1'b0), the transaction is not allowed.

For example, if peripheral 0 is configured as follows:

```
sec_config_0 [7:0] = 8'b0011_0011
```

This peripheral can only be accessed by secure transactions. Bits 0, 1, 4, and 5 are asserted and these bits refer to the four types of secure transactions. If an insecure transaction is attempted to this peripheral, it will result in an error.

Eight bits per peripheral across an entire system can result in a large number of configuration bits that must be assigned and controlled, most likely in a series of registers in another block. To reduce the number of register bits required predefined sets of security profiles can be defined and encapsulated in an external security translation block. The table below describes one set of security profiles that has been proposed for use with the AIPSTZ.

**Table 31-4. Security Levels**

CSU_SEC_LEVEL	Non-Secure User	Non-Secure Supervisor	Secure User	Secure Supervisor
0	RD+WR	RD+WR	RD+WR	RD+WR
1	NOT ALLOWED	RD+WR	RD+WR	RD+WR
2	Read Only	Read Only	RD+WR	RD+WR
3	NOT ALLOWED	Read Only	RD+WR	RD+WR
4	NOT ALLOWED	NOT ALLOWED	RD+WR	RD+WR
5	NOT ALLOWED	NOT ALLOWED	NOT ALLOWED	RD+WR
6	NOT ALLOWED	NOT ALLOWED	Read Only	Read Only
7	NOT ALLOWED	NOT ALLOWED	NOT ALLOWED	NOT ALLOWED

Information regarding CSU is provided in the Security Reference Manual. Contact your NXP representative for information about obtaining this document.

A 3-bit input, 8-bit output translation block can be used such that only three register bits are required to set the security profile and the translation block will drive the correct 8-bit configuration vector. Each peripheral connected to the AIPSTZ would require this translation block. The top level AIPSTZ has this three bit input line `csu\_sec\_level[2:0]' corresponding to each peripheral X.

## 31.8 AIPSTZ Memory Map/Register Definition

The memory map for the AIPS SW-visible registers is shown in the table below.

The MPROT and OPACR fields are 4 bits in width. Some bits may be reserved depending on device.

**AIPSTZ memory map**

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page

### 31.8.1 Master Priviledge Registers (AIPSTZx\_MPR)

Each AIPSTZ\_MPR specifies 16 4-bit fields defining the access privilege level associated with a bus master in the platform, as well as specifying whether write accesses from this master are bufferable shown in [Table 31-5](#)

The registers provide one field per bus master, where field 15 corresponds to master 15, field 14 to master 14,... field 0 to master 0 (typically the processor core). The master index allocation is shown in .

**Table 31-5. MPROT Field**

Bit	Field	Description
3	MBW	<b>Master Buffer Writes</b> - This bit determines whether the AIPSTZ is enabled to buffer writes from this master.
2	MTR	<b>Master Trusted for Reads</b> - This bit determines whether the master is trusted for read accesses.
1	MTW	<b>Master Trusted for Writes</b> - This bit determines whether the master is trusted for write accesses.
0	MPL	<b>Master Privilege Level</b> - This bit determines how the privilege level of the master is determined.

**NOTE**

The reset value is set to 0000\_0000\_7700\_0000, which makes master 0 and master 1 (Arm CORE) the trusted masters. Trusted software can change the settings after reset.

**Table 31-6. Master Index Allocation**

Master Index	Master Name	Comments
Master 0	Arm core	
Master 1	eDMA	
Master 2	DCP	
Master 3	Others	Share the same number allocation.
Master 4-15	Reserved

### 31.8.2 Off-Platform Peripheral Access Control Registers (AIPSTZx\_OPACR)

Each of the off-platform peripherals have an Off-platform Peripheral Access Control Register (AIPSTZ\_OPACR) which defines the access levels supported by the given block.

Each AIPSTZ\_OPACR has the following format shown in [Table 31-7](#)

**Table 31-7. OPAC Field**

Bit	Field	Description
3	BW	<b>Buffer Writes</b> - This bit determines whether write accesses to this peripheral are allowed to be buffered. <sup>1</sup>
2	SP	<b>Supervisor Protect</b> - This bit determines whether the peripheral requires supervisor privilege level for access.
1	WP	<b>Write Protect</b> - This bit determines whether the peripheral allows write accesses.
0	TP	<b>Trusted Protect</b> - This bit determines whether the peripheral allows accesses from an untrusted master.

1. Buffered writes are not available for AIPSTZ. This bit should be set to '0'.

# Chapter 32

## Display and Camera Overview

### 32.1 Display and Camera Overview

The following modules are a part of the Display and Camera system:

- LCD Interface (LCDIF): 24-bit parallel RGB LCD interface
- PXP pixel pipeline: 2D graphics and pixel/image processing engine
- Camera Sensor Interface (CSI): up to 24-bit parallel interface for image sensor

The following figure shows the high-level integration scheme of the chip display and camera system.

Figure 32-1. Block Diagram

### 32.1.1 PiXel Processing Pipeline

The pixel processing pipeline is used to perform image processing on image/video buffers before sending to an LCD display.

The main features of PXP include:

- Multiple input/output format support, including YUV/RGB/Grayscale
- Supports both RGB/YUV scaling
- Supports overlay with Alpha blending
- Supports Rotation of 0, 90, 180, and 270 degrees in conjunction with vertical and horizontal flip options

### 32.1.2 LCD Interface

The LCDIF is a general purpose display controller that is used to drive a wide range of display devices. These displays can vary in size and capability. Many of these displays have had an asynchronous parallel MPU interface for command and data transfer to an integrated frame buffer. There are other popular displays that support moving pictures and require the RGB interface mode (called DOTCLK interface in this document) or the VSYNC mode for high-speed data transfers.

The block has several major features:

- Bus master interface to source frame buffer data for display refresh and a DMA interface to manage input data transfers from the LCD requiring minimal CPU overhead.
- 8/16/18/24 bit LCD data bus support available depending on I/O mux options.
- Programmable timing and parameters for MPU, VSYNC and DOTCLK LCD interfaces to support a wide variety of displays.

### 32.1.3 CMOS Sensor Interface

The CSI enables the chip to connect directly to external CMOS image sensors. CMOS image sensors are separated into two classes, dumb and smart. Dumb sensors are those that support only traditional sensor timing (Vertical SYNC and Horizontal SYNC) and

output only Bayer and statistics data, while smart sensors support CCIR656 video decoder formats and perform additional processing of the image (for example, image compression, image pre-filtering, and various data output formats).

The capabilities of the CSI include:

- Configurable interface logic to support most commonly available CMOS sensors.
- Support for CCIR656 video interface as well as traditional sensor interface.
- 8-bit data port for YCC, YUV, or RGB data input.
- 8-bit/10-bit/16-bit data port for Bayer data input.
- Full control of 8-bit/pixel, 10-bit/pixel or 16-bit/pixel data format to 64-bit receive FIFO packing.
- Embedded DMA controllers to transfer data from receive FIFO or statistic FIFO through AHB bus.
- Support for double buffering two frames in the external memory.
- Single interrupt source to interrupt controller from maskable interrupt sources:
  - Start of Frame
  - End of Frame
  - Change of Field
  - FIFO full
  - FIFO overrun
  - DMA transfer done
  - CCIR error
  - AHB bus response error
- Configurable master clock frequency output to sensor.
- Statistic data generation for Auto Exposure (AE) and Auto White Balance (AWB) control of the camera (only for Bayer data and 8-bit/pixel format).

### 33.2 Overview

This chapter presents the CMOS Sensor Interface (CSI) architecture, operation principles, and programming model.

The CSI enables the chip to connect directly to external CMOS image sensors. CMOS image sensors are separated into two classes, dumb and smart. Dumb sensors are those that support only traditional sensor timing (Vertical SYNC and Horizontal SYNC) and output only Bayer and statistics data, while smart sensors support CCIR656 video decoder formats and perform additional processing of the image (for example, image compression, image pre-filtering, and various data output formats).

The capabilities of the CSI include:

- Configurable interface logic to support most commonly available CMOS sensors.
- Support for CCIR656 video interface as well as traditional sensor interface.

- 8-bit / 10-bit / 16-bit data port for Bayer data input.
- Full control of 8-bit/pixel, 10-bit/pixel or 16-bit / pixel data format to 64-bit receive FIFO packing.
- Receive FIFO overrun protection mechanism.
- Embedded DMA controllers to transfer data from receive FIFO or statistic FIFO through AHB bus.
- Support 2D DMA transfer from the receive FIFO to the frame buffers in the external memory.
- Support double buffering two frames in the external memory.
- Single interrupt source to interrupt controller from maskable interrupt sources: Start of Frame, End of Frame, Change of Field, FIFO full, FIFO overrun, DMA transfer done, CCIR error and AHB bus response error.
- Configurable master clock frequency output to sensor.
- Statistic data generation for Auto Exposure (AE) and Auto White Balance (AWB) control of the camera (only for Bayer data and 8-bit/pixel format).

### 33.3 External Signals

The table below describes the external signals for the CSI. The external signals are tied between the CSI module and an external CMOS sensor.

**Table 33-2. CSI External Signals**

Signal	Description	Pad	Mode	Direction

## 33.4 Clocks

The following table describes the clock sources for CSI. Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information.

**Table 33-3. CSI Clocks**

Clock name	Clock Root	Description
csi_hclk	ipg_clk_root	Module clock
ipg_clk	ipg_clk_root	Peripheral clock
ipg_clk_s	ipg_clk_root	Peripheral access clock
ipg_clk_s_raw	ipg_clk_root	Peripheral raw data clock

## 33.5 Principles of Operation

The information found here describes the modes of operation of the sensor interface.

The CSI is designed to support generic sensor interface timing as well as CCIR656 video interface timing. Traditional CMOS sensors typically use VSYNC (SOF), HSYNC (BLANK), and PIXCLK signals to output Bayer or YUV data. Smart CMOS sensors, that

come with on-chip imaging processing, usually support video mode transfer. They use an embedded timing codec to replace the VSYNC and HSYNC signal. The timing codec is defined by the CCIR656 standard.

The CSI can support connection with the sensor as follows.

- To connect with one 8-bit sensor, the sensor data interface should connect to CSI\_DATA[9:2].
- To connect with one 10-bit sensor, the sensor data interface should connect to CSI\_DATA[9:0].
- To connect with one 16-bit sensor, the sensor data interface should connect to CSI\_DATA[15:0].

### 33.5.1 Data Transfer with the Embedded DMA Controllers

The CSI has two embedded DMA controllers, one for the receive FIFO and the other for the statistic FIFO. It supports 2D DMA transfer from the receive FIFO to the frame buffers in the external memory and linear DMA transfer from the statistic FIFO.

To transfer data from the Rx FIFO to the external memory, the user should set the start address in the frame buffer where the transferred data is stored, the parameters of the frame buffers, and the parameters of the image coming from the sensor. The user can have two frame buffers in the external memory. Each one will store a frame of image coming from the sensor. The embedded DMA controller will first write the frame buffer1 and then frame buffer2. These two frame buffers will be written by turns. The start address should be aligned in double words and set in the CSIDMASA-FB1 and CSIDMASA-FB2 registers. In the CSIFBUF\_PARA register, the user should set the stride of the frame buffer to show how many double words to skip before starting to write the next row of the image. In the CSIIMAG\_PARA register, the user should set the width and height of the image coming from the sensor. The RxFF\_LEVEL and DMA\_REQ\_EN\_RFF bits in CSICR3 registers also need to be set before the data transfer starts. When the number of the data in the Rx FIFO reaches the trigger level, a DMA request will be sent to the embedded DMA controller and the data will be read out

from the RxFIFO and written through AHB bus into the external frame buffers. The burst type of transfer can be INCR4, INCR8 and INCR16 by setting DMA\_BURST\_TYPE\_RFF bits in CSICR2 register. After all data in an image frame are transferred, the DMA\_TSF\_DONE\_FB1 or DMA\_TSF\_DONE\_FB2 bit will be set in CSISR register and the interrupt can be triggered if the corresponding enable bit is set in CSICR1 register. The DMA\_REFLASH\_RFF bit in CSICR3 can be used to activate or restart the embedded DMA controller.

The RxFIFO has the overrun protection mechanism in case the RxFIFO is overrun during data transfer. If the RxFIFO is full and more data needs to be received during the data transfer, the RxFIFO will be overwritten continuously and all 128 words of data in the RxFIFO before overrun occurred will be discarded; the corresponding 128 words memory space in the frame buffer will keep the previous values.

To transfer data from the statistic FIFO to the external memory, the user should set the start address of the external memory where the transferred data is stored and the total transfer sizes. The start address and the transfer sizes are all aligned in double words and should be set in the CSIDMASA-STATFIFO and CSIDMATS-STATFIFO registers. The STATFF\_LEVEL and DMA\_REQ\_EN\_SFF bits in CSICR3 registers should also be set before the data transfer starts. When the number of the data in the STATFIFO reaches the trigger level, a dma request will be sent to the embedded DMA controller and the data will be read out from the STATFIFO and written through AHB bus into the external memory. The burst type of transfer can be INCR4, INCR8 and INCR16 by setting DMA\_BURST\_TYPE\_SFF bits in CSICR2 register. After all expected data (defined by the total transfer sizes) are transferred, the DMA\_TSF\_DONE\_SFF bit will be set in CSISR register and an interrupt can be triggered if the SFF\_DMA\_DONE\_INTEN is enabled in CSICR1 register. The DMA\_REFLASH\_SFF bit in CSICR3 can be used to activate or re-start the embedded DMA controller.

### 33.5.2 Gated Clock Mode

VSYNC, HSYNC, and PIXCLK signals are used in gated clock mode.

A frame starts with an active edge on VSYNC, then HSYNC asserts and holds for the entire line. The Pixel clock is valid as long as HSYNC is asserted. Data is latched at the active edge of the valid pixel clocks. HSYNC deasserts at the end of line. Pixel clocks then become invalid and CSI stops receiving data from the stream. For the next line the HSYNC timing repeats. For the next frame the VSYNC timing repeats.

### 33.5.3 Non-Gated Clock Mode

In non-gated clock mode, only the VSYNC and PIXCLK signals are used; the HSYNC signal is ignored.

**Figure 33-1. Non-Gated Clock Mode Timing Diagram**

The overall timing of non-gated mode is the same as the gated-clock mode, except for the HSYNC signal. HSYNC signal is ignored by the CSI. All incoming pixel clocks are valid and cause data to be latched into Rx FIFO. The PIXCLK signal is inactive (states low) until valid data is ready to be transmitted over the bus.

Figure 33-1 shows the timing of a typical sensor. Other sensors may have the slightly different timing from that shown. The CSI can be programmed to support rising/falling-edge triggered VSYNC, active-high/low HSYNC, and rising/falling-edge triggered PIXCLK.

### 33.5.4 CCIR656 Interlace Mode

In CCIR656 interlace mode, only the PIXCLK and CSI\_DATA[9:2] signals are used. The start of frame and blank signals are replaced by a timing codec which is embedded in the data stream. Each active line starts with an Start of Active Video (SAV) code and ends with an End of Active Video (EAV) code. In some cases, digital blanking is inserted in between EAV and SAV code. The CSI decodes and filters out the timing-coding from the data stream, recovering VSYNC and HSYNC signals for internal use, such as statistical block control. Data is forwarded to the data receive and packing block in a sequential manner without reordering—that is, field 1 followed by field 2. The fields must be reordered in software to get back the original image.

Change of Field (COF) interrupt is triggered upon every field change. The interrupt service routine reads the status register to check for the current field.

According to the CCIR656 specification, the image must be in 625/50 PAL or 525/60 NTSC format. In addition, the image is interlaced into odd and even fields with vertical and horizontal blank data being filled into certain lines. Data must be in YCbCr422 format, each pixel contains 2 bytes, either Y + Cr or Y + Cb. These requirements are set for TV systems. The CSI module supports PAL and NTSC format only.

The following figure describes the frame structure in PAL system, showing vertical and horizontal blanking.

Figure 33-2. CCIR656 Interlace Mode (PAL)

The following figure describes the general timing for a single line, showing SAV and EAV.

Figure 33-3. CCIR656 General Line Timing

The coding tables recommended by the CCIR656 specification are shown below. It is used in the CCIR656 mode to decode the video stream. An interrupt is generated for SOF, which is decoded from the embedded timing codec.

**Table 33-5. Coding for SAV and EAV**

Data Bit Number	1st Byte 0xFF	2nd Byte 0x00	3rd Byte 0x00	4th Byte 0xXY
7 (MSB)	1	0	0	1
6	1	0	0	F
5	1	0	0	V
4	1	0	0	H
3	1	0	0	P3
2	1	0	0	P2
1	1	0	0	P1
0	1	0	0	P0

**Table 33-6. Codes with Protection bits for Error Detection/Correction**

F	V	H	P3	P2	P1	P0
0	0	0	0	0	0	0
0	0	1	1	1	0	1
0	1	0	1	0	1	1
0	1	1	0	1	1	0
1	0	0	0	1	1	1
1	0	1	1	0	1	0
1	1	0	1	1	0	0
1	1	1	0	0	0	1

**Table 33-7. Representations by F-Bit**

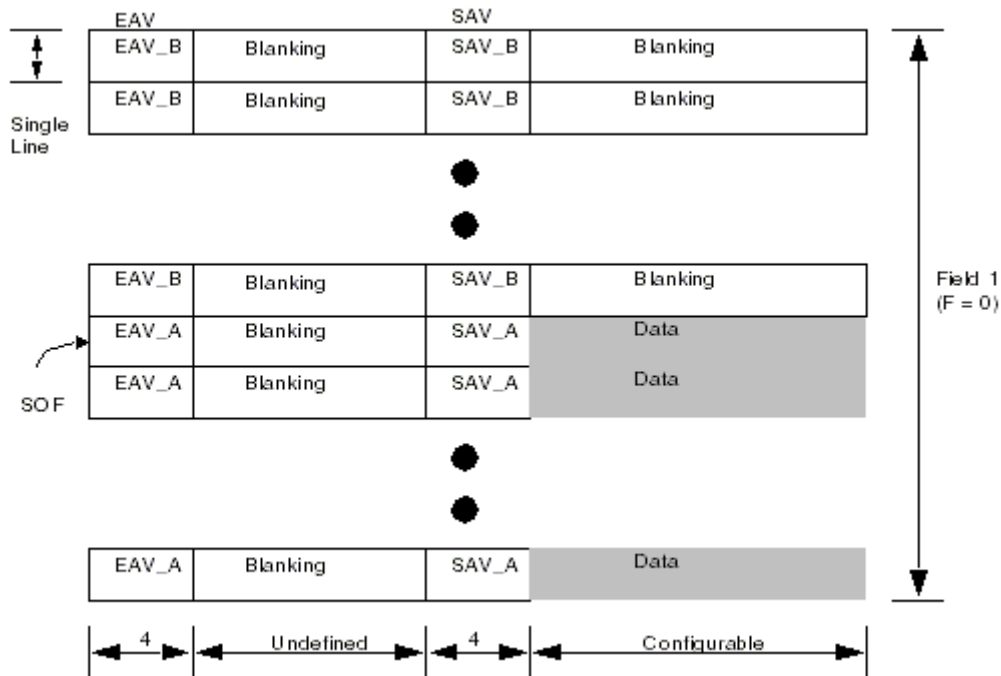

F-Bit	Representations
0	ODD FIELD (FIELD 1)
1	EVEN FIELD (FIELD 2)

### 33.5.5 CCIR656 Progressive Mode

For a CMOS camera system of VGA or CIF resolution, strict adherence to the interlace requirements stated in the CIR standard is not required.

The image is considered to have only 1 active field which is scanned in a progressive manner. This active field is regarded as field 1 and the F-bit in the timing codec is ignored by the decoder. Most sensors support CCIR timing in this mode (progressive) by default.

The following figure shows the typical flow of progressive mode.

**Figure 33-4. CCIR656 Progressive Mode (General Case)**

An interrupt is generated for SOF but not for COF. In the general case, when SOF information is retrieved from the embedded coding, it is known as internal VSYNC mode. In other cases, when the VSYNC signal is provided by the sensor, it is known as external VSYNC mode. The CSI can be operated in internal or external VSYNC mode.

### 33.5.6 Error Correction for CCIR656 Coding

According to the algorithm for CCIR coding, protection bits in the SAV and EAV are encoded in the way that allows a 1-bit error to be corrected, or a 2-bit error to be detected by the decoder. This feature is supported by the interlace mode CCIR decoder in CSI.

For the 1-bit error case, users can select the error to be corrected automatically, or simply shown as a status flag instead. For the 2-bit error case, because the decoder is unable to make a correction, the error would be shown as a status flag only.

An interrupt can be generated upon the detection of an error. This signal can be enabled or disabled without affecting the operation of the status bit.

## 33.6 Interrupt Generation

The information found here describes CSI events that generate interrupts.

### 33.6.1 Start Of Frame Interrupt (SOF\_INT)

The source of an SOF interrupt is dependent on the mode of operation.

In traditional mode, VSYNC signal is taken from sensor and SOF\_INT is generated at the rising or falling edge (programmable) of VSYNC.

In CCIR interlace mode, the SOF interrupt information is retrieved from the embedded coding and SOF\_INT is generated.

In CCIR progressive mode, there are two sources of an SOF interrupt:

- In *internal* VSYNC mode, SOF is retrieved from the embedded coding.
- In *external* VSYNC mode, VSYNC is taken from the sensor and SOF is generated at the rising edge of VSYNC.

### 33.6.2 End Of Frame Interrupt (EOF\_INT)

An EOF interrupt is generated when the frame ends and the complete frame data in RXFIFO is read.

The EOF event triggering works with the RX count register (CSIRXCNT). Software sets the RX count register to the frame size (in words). The CSI RX logic then counts the number of pixel data being received and compares it with the RX count. If the preset value is reached, an EOF interrupt is generated and the data in the RXFIFO are read. If a SOF event is detected before this happens, the EOF interrupt is not generated.

### 33.6.3 Change Of Field Interrupt (COF\_INT)

The Change of Field interrupt is only valid in CCIR Interlace mode. The COF interrupt is generated when the field toggles, either from field 1 to field 2, or field 2 to field 1.

Software should first check COF\_INT bit in the CSI Status Register (CSISTAT) before checking that F1\_INT or F2\_INT is turned on.

In PAL systems, the field changes at the beginning of the frame and coincides with SOF. For the first field, a COF interrupt is not generated, only an SOF. The COF interrupt is generated for the second field.

### 33.6.4 CCIR Error Interrupt (ECC\_INT)

The CCIR Error Interrupt is only valid for CCIR Interlace mode. An ECC interrupt is generated when an error is found on the SAV or EAV codes in the incoming stream. When this happens, the ECC\_INT status bit is set.

### 33.6.5 RxFIFO Full Interrupt (RxFF\_INT)

A RxFIFO full interrupt is generated when the number of data in RXFIFO reaches the water mark defined by RxFF\_LEVEL in CSICR3.

### 33.6.6 Statistic FIFO Full Interrupt (STATFF\_INT)

A StatFIFO full interrupt is generated when the number of data in STATFIFO reaches the water mark defined by STATFF\_LEVEL in CSICR3.

### 33.6.7 RxFIFO Overrun Interrupt (RFF\_OR\_INT)

A RxFIFO Overrun interrupt is generated when the RxFIFO has 128 words data and more data is being written in.

### 33.6.8 Statistic FIFO Overrun Interrupt (SFF\_OR\_INT)

A StatFIFO Overrun interrupt is generated when the STATFIFO has 64 words data and more data is being written in.

### 33.6.9 Frame Buffer1 DMA Transfer Done Interrupt (DMA\_TSF\_DONE\_FB1)

A DMA transfer done interrupt of frame buffer1 is generated when one frame of data are transferred from RxFIFO to the frame buffer1 in the external memory.

### **33.6.10 Frame Buffer2 DMA Transfer Done Interrupt (DMA\_TSF\_DONE\_FB2)**

A DMA transfer done interrupt of frame buffer2 is generated when one frame of data are transferred from RxFIFO to the frame buffer2 in the external memory.

### **33.6.11 Statistic FIFO DMA Transfer Done Interrupt (DMA\_TSF\_DONE\_SFF)**

A StatFIFO DMA transfer done interrupt is generated when all the data are transferred from StatFIFO to the external memory. The transfer size is defined in the STATFIFO DMA Transfer Size Register.

### **33.6.12 AHB Bus Response Error Interrupt (HRESP\_ERR\_INT)**

An AHB Bus response error interrupt is generated when a bus error is detected.

## **33.7 Data Packing Style**

Careful attention to endianness is needed given the different port sizes at different stages of the image capture path.

To enable flexible packing of image data before storage in the FIFOs, the CSI module can swap data fields by use of the PACK\_DIR and the SWAP16\_EN bit in CSI Control Register 1 (CSICR1).

The CSI module accepts 8-bit, 10-bit or 16-bit data from the sensor by configuring PIXEL\_BIT bit in CSI Control Register 1 (CSICR1) and TWO\_8BIT\_SENSOR bit in CSI Control Register3 (CSICR3). The input data is packed according to the setting of PACK\_DIR bit. The packed data is stored in the RX FIFO according to the setting of the SWAP16\_EN bit.

For 10-bit per pixel data format, each pixel is expanded to 16 bits by appending 6 zeros bits to the most significant bit.

## 33.7.1 RX FIFO Path

### 33.7.1.1 Bayer Data

Bayer data is a type of raw data from the image sensor. This byte-wide data must be converted to the RGB space or YUV space by software. The data path for Bayer data is from the CSI to memory. If the system is in little endian, then the `PACK_DIR` bit should be set to 0. 8-bit data format from a sensor is packed to 64 bits as `P7.P6.P5.P4.P3.P2.P1.P0`, where `P0` is the pixel coming in time slot 0 (first data) and `P3` is the pixel coming in time slot 3 (the last data in the 64-bit word). When the data is addressed as bytes by software, `P0` is transferred first, `P1` is transferred next, and so on. 10-bit data format is packed to 64 bits as `000000.P3.000000.P2.000000.P1.000000.P0`, where `P0` is the 10-bit data coming in time slot 0 (first pixel) and `P3` is the 10-bit data coming in time slot 3 (fourth pixel). 16-bit data is packed to 64 bits as `P7.P6.P5.P4.P3.P2.P1.P0`.

### 33.7.1.2 RGB565 Data

RGB565 data is processed data from the image sensor, which can be put directly into the display buffer. The data is 16 bits wide. The data path is from CSI to memory to the display controller. On the sensor side, data must be transmitted as `P0` first, followed by `P1`, and so on. For each pixel, whether the MSB or LSB is sent first depends on the endianness of the sensor. Data is 16 bits wide with the MSB labeled `RG`, and the LSB labeled `GB`. `P0` is represented as `RG0` and `GB0`.

CSI receives data in one of the following sequence:

- `RG0, GB0, RG1, GB1`, while `RG0` comes out at time slot 0 (first data), and `GB1` comes out at time slot 3 (last data)
- `GB0, RG0, GB1, RG1`

Using the first sequence as an example, and assuming the system is running in little endian, the data is presented as:

- 8-bit data from sensor: `RG0, GB0, RG1, GB1, ...`
- 64-bit data before storage in the CSI RX FIFO (`PACK_DIR` bit = 1):  
`RG0GB0RG1GB1RG2GB2RG3GB3`
- 64-bit data in CSI RX FIFO (`SWAP16_EN` bit enabled):  
`RG3GB3RG2GB2RG1GB1RG0GB0`

- 64-bit transfer to system memory: RG3GB3RG2GB2RG1GB1RG0GB0
- 16-bit read by display controller: RG0GB0, RG1GB1

### 33.7.1.3 RGB888 Data

This is another kind of processed data from image sensor, which can be used for further image processing directly. Each of the data consist of 8-bit Red, 8-bit Green, and 8-bit Blue data. An example of timing scheme is shown in the following figure.

**Figure 33-5. Sample Timing Diagram for RGB888 8 bits/cycle Data**

An optional scheme to pack a dummy byte is provided. For every group of 3 bytes data, a dummy zero is packed to form a 32-bit word as shown in the following figure. The dummy zero can be packed at the LSB position or MSB position. Using RGB888A\_FORMAT\_SEL in CSI\_CSICR18[18] to determine to put the dummy bytes packed at LSB or MSB position.

### 33.7.2 STAT FIFO Path

Statistics only works for Bayer data in 8-bit per pixel format. It generates 16-bit statistical output from the 8-bit Bayer input (CSI\_DATA[13:6]). The outputs are Sum of Green (G), Sum of Red (R), Sum of Blue (B), and Auto Focus (F). Each output is 16-bits wide.

The settings of PACK\_DIR and SWAP16\_EN bits in the CSICR1 register have no effect on the input path. The PACK\_DIR only controls how the 16-bit stat output is packed into the 32-bit STAT FIFO.

When the PACK\_DIR bit = 1, the stat data is packed as:

First 32-bit: RG

Second 32-bit: BF

...

When the PACK\_DIR bit = 0, the stat data is packed as:

First 32-bit GR

Second 32-bit: FB

...

## 33.8 CSI Memory Map/Register Definition

All the 32-bit registers of the CSI module are summarized in the Memory Map below:

**CSI memory map**

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
402B_C000	CSI Control Register 1 (CSI_CSICR1)	32	R/W	4000_0800h	<a href="#">33.8.1/1924</a>

### 33.8.1 CSI Control Register 1 (CSI\_CSICR1)

This register controls the sensor interface timing and interrupt generation. The interrupt enable bits in this register control the interrupt signals and the status bits. That means status bits will only function when the corresponding interrupt bits are enabled.

Address: 402B\_C000h base + 0h offset = 402B\_C000h

#### CSI\_CSICR1 field descriptions

Field	Description
31 SWAP16_EN	<p>SWAP 16-Bit Enable. This bit enables the swapping of 16-bit data. Data is packed from 8-bit or 10-bit to 32-bit first (according to the setting of PACK_DIR) and then swapped as 16-bit words before being put into the RX FIFO. The action of the bit only affects the RX FIFO and has no affect on the STAT FIFO.</p> <p><b>NOTE:</b> Example of swapping enabled: Data input to FIFO = 0x11223344 Data in RX FIFO = 0x 33441122</p> <p><b>NOTE:</b> Example of swapping disabled: Data input to FIFO = 0x11223344 Data in RX FIFO = 0x11223344</p>

Table continues on the next page...

## CSI\_CSICR1 field descriptions (continued)

Field	Description
	0 Disable swapping 1 Enable swapping
30 EXT_VSYNC	External VSYNC Enable. This bit controls the operational VSYNC mode. <b>NOTE:</b> This only works when the CSI is in CCIR progressive mode. 0 Internal VSYNC mode 1 External VSYNC mode
29 EOF_INT_EN	End-of-Frame Interrupt Enable. This bit enables and disables the EOF interrupt. 0 EOF interrupt is disabled. 1 EOF interrupt is generated when RX count value is reached.
28 PrP_IF_EN	CSI-PrP Interface Enable. This bit controls the CSI to PrP bus. When enabled the RxFIFO is detached from the AHB bus and connected to PrP. All CPU reads or DMA accesses to the RxFIFO register are ignored. All CSI interrupts are also masked. 0 CSI to PrP bus is disabled 1 CSI to PrP bus is enabled
27 CCIR_MODE	CCIR Mode Select. This bit controls the CCIR mode of operation. This bit only works in CCIR interface mode. 0 Progressive mode is selected 1 Interlace mode is selected
26 COF_INT_EN	Change Of Image Field (COF) Interrupt Enable. This bit enables the COF interrupt. This bit works only in CCIR interlace mode which is when CCIR_EN = 1 and CCIR_MODE = 1. 0 COF interrupt is disabled 1 COF interrupt is enabled
25 SF_OR_INTEN	STAT FIFO Overrun Interrupt Enable. This bit enables the STATFIFO overrun interrupt. 0 STATFIFO overrun interrupt is disabled 1 STATFIFO overrun interrupt is enabled
24 RF_OR_INTEN	RxFIFO Overrun Interrupt Enable. This bit enables the RX FIFO overrun interrupt. 0 RxFIFO overrun interrupt is disabled 1 RxFIFO overrun interrupt is enabled
23 -	This field is reserved. Reserved. This bit is reserved and should read 0.
22 SFF_DMA_DONE_INTEN	STATFIFO DMA Transfer Done Interrupt Enable. This bit enables the interrupt of STATFIFO DMA transfer done. 0 STATFIFO DMA Transfer Done interrupt disable 1 STATFIFO DMA Transfer Done interrupt enable
21 STATFF_INTEN	STATFIFO Full Interrupt Enable. This bit enables the STAT FIFO interrupt. 0 STATFIFO full interrupt disable 1 STATFIFO full interrupt enable

Table continues on the next page...

## CSI\_CSICR1 field descriptions (continued)

Field	Description
20 FB2_DMA_ DONE_INTEN	Frame Buffer2 DMA Transfer Done Interrupt Enable. This bit enables the interrupt of Frame Buffer2 DMA transfer done.  0 Frame Buffer2 DMA Transfer Done interrupt disable 1 Frame Buffer2 DMA Transfer Done interrupt enable
19 FB1_DMA_ DONE_INTEN	Frame Buffer1 DMA Transfer Done Interrupt Enable. This bit enables the interrupt of Frame Buffer1 DMA transfer done.  0 Frame Buffer1 DMA Transfer Done interrupt disable 1 Frame Buffer1 DMA Transfer Done interrupt enable
18 RXFF_INTEN	RxFIFO Full Interrupt Enable. This bit enables the RxFIFO full interrupt.  0 RxFIFO full interrupt disable 1 RxFIFO full interrupt enable
17 SOF_POL	SOF Interrupt Polarity. This bit controls the condition that generates an SOF interrupt.  0 SOF interrupt is generated on SOF falling edge 1 SOF interrupt is generated on SOF rising edge
16 SOF_INTEN	Start Of Frame (SOF) Interrupt Enable. This bit enables the SOF interrupt.  0 SOF interrupt disable 1 SOF interrupt enable
15–12 Reserved	This field is reserved. Reserved.  This field is reserved.
11 HSYNC_POL	HSYNC Polarity Select. This bit controls the polarity of HSYNC.  This bit only works in gated-clock-that is, GCLK_MODE = 1 and CCIR_EN = 0.  0 HSYNC is active low 1 HSYNC is active high
10 CCIR_EN	CCIR656 Interface Enable. This bit selects the type of interface used. When the CCIR656 timing decoder is enabled, it replaces the function of timing interface logic.  0 Traditional interface is selected. Timing interface logic is used to latch data. 1 CCIR656 interface is selected.
9 Reserved	This field is reserved. This field is reserved.
8 FCC	FIFO Clear Control. This bit determines how the RxFIFO and STATFIFO are cleared. When Synchronous FIFO clear is selected the RxFIFO and STATFIFO are cleared, and STAT block is reset, on every SOF. FIFOs and STAT block restarts immediately after reset. For information on the operation when Asynchronous FIFO clear is selected, refer to the descriptions for the CLR_RXFIFO and CLR_STATFIFO bits.  0 Asynchronous FIFO clear is selected. 1 Synchronous FIFO clear is selected.
7 PACK_DIR	Data Packing Direction. This bit Controls how 8-bit/10-bit image data is packed into 32-bit RX FIFO, and how 16-bit statistical data is packed into 32-bit STAT FIFO.

*Table continues on the next page...*

## CSI\_CSICR1 field descriptions (continued)

Field	Description
	<p>0 Pack from LSB first. For image data, 0x11, 0x22, 0x33, 0x44, it will appear as 0x44332211 in RX FIFO. For stat data, 0xAAAA, 0xBBBB, it will appear as 0xB BBBBAAAA in STAT FIFO.</p> <p>1 Pack from MSB first. For image data, 0x11, 0x22, 0x33, 0x44, it will appear as 0x11223344 in RX FIFO. For stat data, 0xAAAA, 0xBBBB, it will appear as 0xAAAABBBB in STAT FIFO.</p>
6 CLR_STATFIFO	<p>Asynchronous STATFIFO Clear. This bit clears the STATFIFO and Reset STAT block.</p> <p>This bit works only in async FIFO clear mode-that is, FCC = 0. Otherwise this bit is ignored.</p> <p>Writing 1 will clear STATFIFO and reset STAT block immediately, STATFIFO and STAT block then wait and restart after the arrival of next SOF.</p> <p>The bit is restored to 0 automatically after finish. Normally reads 0.</p>
5 CLR_RXFIFO	<p>Asynchronous RXFIFO Clear. This bit clears the RXFIFO.</p> <p>This bit works only in async FIFO clear mode-that is, FCC = 0. Otherwise this bit is ignored.</p> <p>Writing 1 clears the RXFIFO immediately, RXFIFO restarts immediately after that.</p> <p>The bit is restored to 0 automatically after finish. Normally reads 0.</p>
4 GCLK_MODE	<p>Gated Clock Mode Enable. Controls if CSI is working in gated or non-gated mode.</p> <p>This bit works only in traditional mode-that is, CCIR_EN = 0. Otherwise this bit is ignored.</p> <p>0 Non-gated clock mode. All incoming pixel clocks are valid. HSYNC is ignored.</p> <p>1 Gated clock mode. Pixel clock signal is valid only when HSYNC is active.</p>
3 INV_DATA	<p>Invert Data Input. This bit enables or disables internal inverters on the data lines.</p> <p>0 CSI_D[7:0] data lines are directly applied to internal circuitry</p> <p>1 CSI_D[7:0] data lines are inverted before applied to internal circuitry</p>
2 INV_PCLK	<p>Invert Pixel Clock Input. This bit determines if the Pixel Clock (CSI_PIXCLK) is inverted before it is applied to the CSI module.</p> <p>0 CSI_PIXCLK is directly applied to internal circuitry</p> <p>1 CSI_PIXCLK is inverted before applied to internal circuitry</p>
1 REDGE	<p>Valid Pixel Clock Edge Select. Selects which edge of the CSI_PIXCLK is used to latch the pixel data.</p> <p>0 Pixel data is latched at the falling edge of CSI_PIXCLK</p> <p>1 Pixel data is latched at the rising edge of CSI_PIXCLK</p>
0 PIXEL_BIT	<p>Pixel Bit. This bit indicates the bayer data width for each pixel. This bit should be configured before activating or re-starting the embedded DMA controller.</p> <p>0 8-bit data for each pixel</p> <p>1 10-bit data for each pixel</p>

### 33.8.2 CSI Control Register 2 (CSI\_CSICR2)

This register provides the statistic block with data about which live view resolution is being used, and the starting sensor pixel of the Bayer pattern. It also contains the horizontal and vertical count used to determine the number of pixels to skip between the 64 x 64 blocks of statistics when generating statistics on live view image that are greater than 512 x 384.

Address: 402B\_C000h base + 4h offset = 402B\_C004h

**CSI\_CSICR2 field descriptions**

Field	Description
31–30 DMA_BURST_TYPE_RFF	Burst Type of DMA Transfer from RxFIFO. Selects the burst type of DMA transfer from RxFIFO. X0 INCR8 01 INCR4 11 INCR16
29–28 DMA_BURST_TYPE_SFF	Burst Type of DMA Transfer from STATFIFO. Selects the burst type of DMA transfer from STATFIFO. X0 INCR8 01 INCR4 11 INCR16

Table continues on the next page...

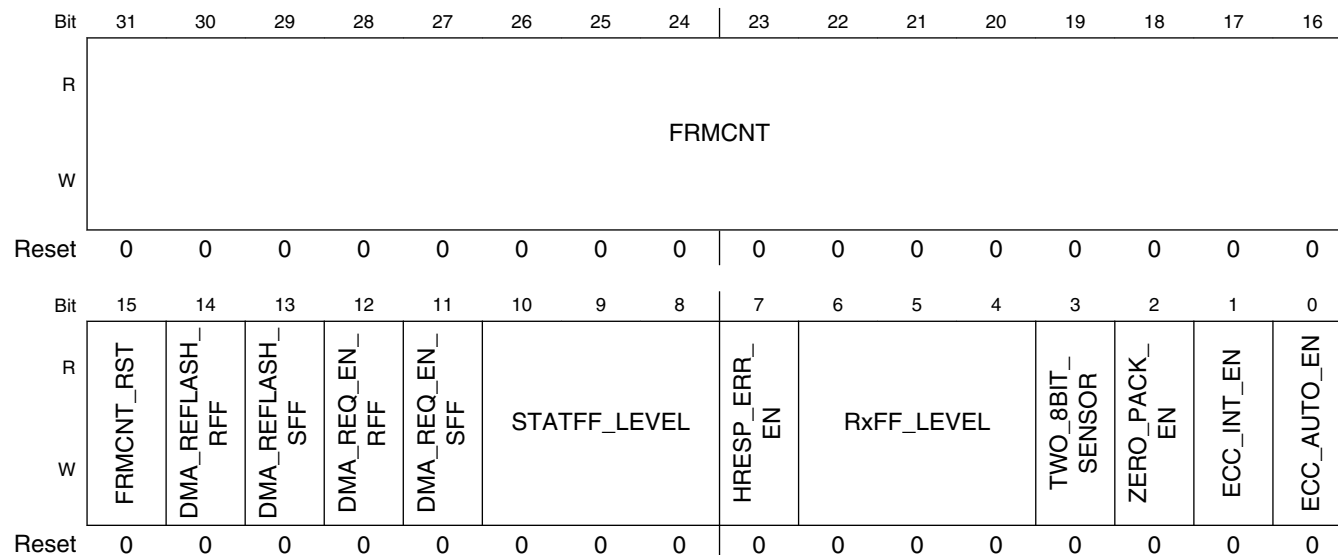

## CSI\_CSICR2 field descriptions (continued)

Field	Description
27 -	This field is reserved. Reserved. These bit is reserved and should read 0.
26 DRM	Double Resolution Mode. Controls size of statistics grid. 0 Stats grid of 8 x 6 1 Stats grid of 8 x 12
25–24 AFS	Auto Focus Spread. Selects which green pixels are used for auto-focus. 00 Abs Diff on consecutive green pixels 01 Abs Diff on every third green pixels 1x Abs Diff on every four green pixels
23 SCE	Skip Count Enable. Enables or disables the skip count feature. 0 Skip count disable 1 Skip count enable
22–21 -	This field is reserved. Reserved. These bits are reserved and should read 0.
20–19 BTS	Bayer Tile Start. Controls the Bayer pattern starting point. 00 GR 01 RG 10 BG 11 GB
18–16 LVRM	Live View Resolution Mode. Selects the grid size used for live view resolution. 0 512 x 384 1 448 x 336 2 384 x 288 3 384 x 256 4 320 x 240 5 288 x 216 6 400 x 300
15–8 VSC	Vertical Skip Count. Contains the number of rows to skip. SCE must be 1, otherwise VSC is ignored. 0-255 Number of rows to skip minus 1
HSC	Horizontal Skip Count. Contains the number of pixels to skip. SCE must be 1, otherwise HSC is ignored. 0-255 Number of pixels to skip minus 1

### 33.8.3 CSI Control Register 3 (CSI\_CSICR3)

This read/write register acts as an extension of the functionality of the CSI Control register 1, adding additional control and features.

Address: 402B\_C000h base + 8h offset = 402B\_C008h

#### CSI\_CSICR3 field descriptions

Field	Description
31–16 FRMCNT	Frame Counter. This is a 16-bit Frame Counter (Wraps around automatically after reaching the maximum)
15 FRMCNT_RST	Frame Count Reset. Resets the Frame Counter. (Cleared automatically after reset is done) 0 Do not reset 1 Reset frame counter immediately
14 DMA_REFLASH_RFF	Reflash DMA Controller for RxFIFO. This bit reflash the embedded DMA controller for RxFIFO. It should be reflash before the embedded DMA controller starts to work. (Cleared automatically after reflash is done) 0 No reflash 1 Reflash the embedded DMA controller
13 DMA_REFLASH_SFF	Reflash DMA Controller for STATFIFO. This bit reflash the embedded DMA controller for STATFIFO. It should be reflash before the embedded DMA controller starts to work. (Cleared automatically after reflash is done) 0 No reflash 1 Reflash the embedded DMA controller

Table continues on the next page...

## CSI\_CSICR3 field descriptions (continued)

Field	Description
12 DMA_REQ_EN_ RFF	DMA Request Enable for RxFIFO. This bit enables the dma request from RxFIFO to the embedded DMA controller.  0 Disable the dma request 1 Enable the dma request
11 DMA_REQ_EN_ SFF	DMA Request Enable for STATFIFO. This bit enables the dma request from STATFIFO to the embedded DMA controller.  0 Disable the dma request 1 Enable the dma request
10–8 STATFF_LEVEL	STATFIFO Full Level. When the number of data in STATFIFO reach this level, STATFIFO full interrupt is generated, or STATFIFO DMA request is sent.  000 4 Double words 001 8 Double words 010 12 Double words 011 16 Double words 100 24 Double words 101 32 Double words 110 48 Double words 111 64 Double words
7 HRESP_ERR_ EN	Hresponse Error Enable. This bit enables the hresponse error interrupt.  0 Disable hresponse error interrupt 1 Enable hresponse error interrupt
6–4 RxFF_LEVEL	<b>RxFIFO Full Level.</b> When the number of data in RxFIFO reaches this level, a RxFIFO full interrupt is generated, or an RxFIFO DMA request is sent.  000 4 Double words 001 8 Double words 010 16 Double words 011 24 Double words 100 32 Double words 101 48 Double words 110 64 Double words 111 96 Double words
3 TWO_8BIT_ SENSOR	16-bit Sensor Mode. This bit indicates one 16-bit sensor connected to the 16-bit data ports. This bit should be set if there is one 16-bit sensor connected. This bit should be configured before activating or restarting the embedded DMA controller.  0 Only one 8-bit sensor is connected. 1 One 16-bit sensor is connected.
2 ZERO_PACK_ EN	Dummy Zero Packing Enable. This bit causes a dummy zero to be packed with every 3 incoming bytes, forming a 32-bit word. The dummy zero is always packed to the LSB position. This packing function is only available in 8-bit/pixel mode.  0 Zero packing disabled 1 Zero packing enabled

Table continues on the next page...

**CSI\_CSICR3 field descriptions (continued)**

Field	Description
1 ECC_INT_EN	<p>Error Detection Interrupt Enable. This bit enables and disables the error detection interrupt. This feature only works in CCIR interlace mode.</p> <p>0 No interrupt is generated when error is detected. Only the status bit ECC_INT is set.                      1 Interrupt is generated when error is detected.</p>
0 ECC_AUTO_EN	<p>Automatic Error Correction Enable. This bit enables and disables the automatic error correction. If an error occurs and error correction is disabled only the ECC_INT status bit is set. This feature only works in CCIR interlace mode.</p> <p>0 Auto Error correction is disabled.                      1 Auto Error correction is enabled.</p>

**33.8.4 CSI Statistic FIFO Register (CSI\_CSISTATFIFO)**

The StatFIFO is a read-only register containing statistic data from the sensor. Writing to this register has no effect.

Address: 402B\_C000h base + Ch offset = 402B\_C00Ch

**CSI\_CSISTATFIFO field descriptions**

Field	Description
STAT	Static data from sensor

**33.8.5 CSI RX FIFO Register (CSI\_CSIRFIFO)**

This read-only register contains received image data. Writing to this register has no effect.

Address: 402B\_C000h base + 10h offset = 402B\_C010h

**CSI\_CSIRFIFO field descriptions**

Field	Description
IMAGE	Received image data

**33.8.6 CSI RX Count Register (CSI\_CSIRXCNT)**

This register works for EOF interrupt generation. It should be set to the number of words to receive that would generate an EOF interrupt.

There is an internal counter that counts the number of words read from the RX FIFO. Whenever the RX FIFO is being read, by either the CPU or the embedded DMA controller, the counter value is updated and compared with this register. If the values match, then an EOF interrupt is triggered.

Address: 402B\_C000h base + 14h offset = 402B\_C014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**CSI\_CSIRXCNT field descriptions**

Field	Description
31–22 -	This field is reserved. Reserved. These bits are reserved and should read 0.
RXCNT	RxFIFO Count. This 22-bit counter for RxFIFO is updated each time the RxFIFO is read by CPU or DMA. This counter should be set to the expected number of words to receive that would generate an EOF interrupt.

### 33.8.7 CSI Status Register (CSI\_CSISR)

This read/write register shows sensor interface status, and which kind of interrupt is being generated. The corresponding interrupt bits must be set for the status bit to function. Status bits should function normally even if the corresponding interrupt enable bits are not enabled.

Address: 402B\_C000h base + 18h offset = 402B\_C018h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CSI\_CSISR field descriptions

Field	Description
31-29 -	Reserved.
28 BASEADDR_CHHANGE_ERROR	When using base address switching enable, this bit will be 1 when switching occur before DMA complete. This bit will be clear by writing 1. When this interrupt happens, follow the steps listed below. 1. Unassert the CSI enable, CSIx_CSICR18 bit31, 2. Reflash the DMA, assert the CSIX_CSICR3 bit 14, 3. Assert the CSI enable, CSIx_CSICR18 bit31.
27 DMA_FIELD0_DONE	When DMA field 0 is complete, this bit will be set to 1(clear by writing 1).

Table continues on the next page...

## CSI\_CSISR field descriptions (continued)

Field	Description
26 DMA_FIELD1_ DONE	When DMA field 0 is complete, this bit will be set to 1 (clear by writing 1).
25 SF_OR_INT	STATFIFO Overrun Interrupt Status. Indicates the overflow status of the STATFIFO register. (Cleared by writing 1)  0 STATFIFO has not overflowed. 1 STATFIFO has overflowed.
24 RF_OR_INT	RxFIFO Overrun Interrupt Status. Indicates the overflow status of the RxFIFO register. (Cleared by writing 1)  0 RxFIFO has not overflowed. 1 RxFIFO has overflowed.
23 -	This field is reserved. Reserved. This bit is reserved and should read 0.
22 DMA_TSF_ DONE_SFF	DMA Transfer Done from StatFIFO. Indicates that the dma transfer from StatFIFO is completed. It can trigger an interrupt if the corresponding enable bit is set in CSICR1. This bit can be cleared by writing 1 or reflashing the StatFIFO dma controller in CSICR3. (Cleared by writing 1)  0 DMA transfer is not completed. 1 DMA transfer is completed.
21 STATFF_INT	STATFIFO Full Interrupt Status. Indicates the number of data in the STATFIFO reaches the trigger level. (this bit is cleared automatically by reading the STATFIFO)  0 STATFIFO is not full. 1 STATFIFO is full.
20 DMA_TSF_ DONE_FB2	DMA Transfer Done in Frame Buffer2. Indicates that the DMA transfer from RxFIFO to Frame Buffer2 is completed. It can trigger an interrupt if the corresponding enable bit is set in CSICR1. This bit can be cleared by by writing 1 or reflashing the RxFIFO dma controller in CSICR3. (Cleared by writing 1)  0 DMA transfer is not completed. 1 DMA transfer is completed.
19 DMA_TSF_ DONE_FB1	DMA Transfer Done in Frame Buffer1. Indicates that the DMA transfer from RxFIFO to Frame Buffer1 is completed. It can trigger an interrupt if the corresponding enable bit is set in CSICR1. This bit can be cleared by by writing 1 or reflashing the RxFIFO dma controller in CSICR3. (Cleared by writing 1)  0 DMA transfer is not completed. 1 DMA transfer is completed.
18 RxFF_INT	RxFIFO Full Interrupt Status. Indicates the number of data in the RxFIFO reaches the trigger level. (this bit is cleared automatically by reading the RxFIFO)  0 RxFIFO is not full. 1 RxFIFO is full.
17 EOF_INT	End of Frame (EOF) Interrupt Status. Indicates when EOF is detected. (Cleared by writing 1)  0 EOF is not detected. 1 EOF is detected.
16 SOF_INT	Start of Frame Interrupt Status. Indicates when SOF is detected. (Cleared by writing 1)

*Table continues on the next page...*

## CSI\_CSISR field descriptions (continued)

Field	Description
	0 SOF is not detected. 1 SOF is detected.
15 F2_INT	CCIR Field 2 Interrupt Status. Indicates the presence of field 2 of video in CCIR mode. (Cleared automatically when current field does not match)  <b>NOTE:</b> Only works in CCIR Interlace mode.  0 Field 2 of video is not detected 1 Field 2 of video is about to start
14 F1_INT	CCIR Field 1 Interrupt Status. Indicates the presence of field 1 of video in CCIR mode. (Cleared automatically when current field does not match)  <b>NOTE:</b> Only works in CCIR Interlace mode.  0 Field 1 of video is not detected. 1 Field 1 of video is about to start.
13 COF_INT	Change Of Field Interrupt Status. Indicates that a change of the video field has been detected. Only works in CCIR Interlace mode. Software should read this bit first and then dispatch the new field from F1_INT and F2_INT. (Cleared by writing 1)  0 Video field has no change. 1 Change of video field is detected.
12–8 -	This field is reserved. Reserved. These bits are reserved and should read 0.
7 HRESP_ERR_INT	Hresponse Error Interrupt Status. Indicates that a hresponse error has been detected. (Cleared by writing 1)  0 No hresponse error. 1 Hresponse error is detected.
6–2 -	This field is reserved. Reserved. These bits are reserved and should read 0.
1 ECC_INT	CCIR Error Interrupt. This bit indicates an error has occurred. This only works in CCIR Interlace mode. (Cleared by writing 1)  0 No error detected 1 Error is detected in CCIR coding
0 DRDY	RXFIFO Data Ready. Indicates the presence of data that is ready for transfer in the RxFIFO. (Cleared automatically by reading FIFO)  0 No data (word) is ready 1 At least 1 datum (word) is ready in RXFIFO.

### 33.8.8 CSI DMA Start Address Register - for STATFIFO (CSI\_CSIDMASA\_STATFIFO)

This register provides the start address for the embedded DMA controller of STATFIFO. The embedded DMA controller will read data from STATFIFO and write it to the external memory from the start address. This register should be configured before activating or restarting the embedded DMA controller.

Address: 402B\_C000h base + 20h offset = 402B\_C020h

Bit	31	30	29	28	27	26	25	24		23	22	21	20	19	18	17	16

W	DMA_TSF_SIZE_SFF																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0		0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**CSI\_CSIDMATS\_STATFIFO field descriptions**

Field	Description
DMA_TSF_SIZE_SFF	DMA Transfer Size for STATFIFO. Indicates how many words to be transferred by the embedded DMA controller. The size should be double words aligned.

**33.8.10 CSI DMA Start Address Register - for Frame Buffer1 (CSI\_CSIDMASA\_FB1)**

This register provides the start address in the frame buffer1 for the embedded DMA controller of RxFIFO. The embedded DMA controller will read data from RxFIFO and write it to the frame buffer1 from the start address. This register should be configured before activating or restarting the embedded DMA controller.

Address: 402B\_C000h base + 28h offset = 402B\_C028h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

#### CSI\_CSIDMASA\_FB2 field descriptions

Field	Description
31–2 DMA_START_ADDR_FB2	DMA Start Address in Frame Buffer2. Indicates the start address to write data. The embedded DMA controller will read data from RxFIFO and write it from this address through AHB bus. The address should be double words aligned.
-	This field is reserved. Reserved. These bits are reserved and should read 0.

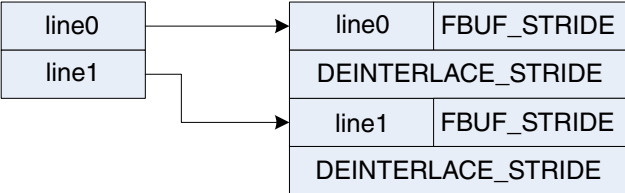

### 33.8.12 CSI Frame Buffer Parameter Register (CSI\_CSIFBUF\_PARA)

This register provides the stride of the frame buffer to show how many words to skip before starting to write the next row of the image. The width of the frame buffer minus the width of the image is the stride. This register should be configured before activating or restarting the embedded DMA controller.

Address: 402B\_C000h base + 30h offset = 402B\_C030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16		15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### CSI\_CSIFBUF\_PARA field descriptions

Field	Description
31–16 DEINTERLACE_STRIDE	<p>DEINTERLACE_STRIDE is only used in the deinterlace mode. If line stride feature is supported in deinterlace mode, FBUF_STRIDE and DEINTERLACE_STRIDE need to be configured at the same time. DEINTERLACE_STRIDE is configured the same as line width. In normal line stride feature, only FBUF_STRIDE needs to be configured.</p> 
FBUF_STRIDE	<p>Frame Buffer Parameter. Indicates the stride of the frame buffer. The width of the frame buffer(in double words) minus the width of the image(in double words) is the stride. The stride should be double words aligned. The embedded DMA controller will skip the stride before starting to write the next row of the image.</p>

### 33.8.13 CSI Image Parameter Register (CSI\_CSIIIMAG\_PARA)

This register provides the width and the height of the image from the sensor. The width and height should be aligned in pixel. The width of the image multiplied by the height is the total pixel size that will be transferred in a frame by the embedded DMA controller. This register should be configured before activating or restarting the embedded DMA controller.

Address: 402B\_C000h base + 34h offset = 402B\_C034h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W	IMAGE_WIDTH																IMAGE_HEIGHT															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### CSI\_CSIIIMAG\_PARA field descriptions

Field	Description
31–16 IMAGE_WIDTH	<p>Image Width. Indicates how many pixels in a line of the image from the sensor.</p> <p>If the input data from the sensor is 8-bit/pixel format, the IMAGE_WIDTH should be a multiple of 8 pixels.</p> <p>If the input data from the sensor is 10-bit/pixel or 16-bit/pixel format, the IMAGE_WIDTH should be a multiple of 4 pixels.</p>
IMAGE_HEIGHT	<p>Image Height. Indicates how many pixels in a column of the image from the sensor.</p>

### 33.8.14 CSI Control Register 18 (CSI\_CSICR18)

This read/write register acts as an extension of the functionality of the CSI Control register 1

Address: 402B\_C000h base + 48h offset = 402B\_C048h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
R	CSI_ENABLE	Reserved												MASK_OPTION		Reserved	
W																	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
R	AHB_HPROT				Reserved	RGB888A_FORMAT_SEL	BASEADDR_CHANGE_ERROR_IE	LAST_DMA_REQ_SEL	DMA_FIELD1_DONE_IE	FIELD0_DONE_IE	BASEADDR_SWITCH_SEL	BASEADDR_SWITCH_EN	PARALLEL24_EN	DEINTERLACE_EN	Reserved		
W																	
Reset	1	1	0	1	0	0	0	0	0	0	0	0	0	0	0	0	

#### CSI\_CSICR18 field descriptions

Field	Description
31 CSI_ENABLE	CSI global enable signal. Only when this bit is 1, CSI can start to receive the data and store to memory.
30–20 -	This field is reserved.
19–18 MASK_OPTION	These bits used to choose the method to mask the CSI input. 00 Writing to memory from first completely frame, when using this option, the CSI_ENABLE should be 1. 01 Writing to memory when CSI_ENABLE is 1. 02 Writing to memory from second completely frame, when using this option, the CSI_ENABLE should be 1. 03 Writing to memory when data comes in, not matter the CSI_ENABLE is 1 or 0.
17–16 -	This field is reserved.

Table continues on the next page...

## CSI\_CSICR18 field descriptions (continued)

Field	Description
15–12 AHB_HPROT	Hprot value in AHB bus protocol.
11 -	This field is reserved.
10 RGB888A_ FORMAT_SEL	Output is 32-bit format. 0 {8'h0, data[23:0]} 1 {data[23:0], 8'h0}
9 BASEADDR_ CHANGE_ ERROR_IE	Base address change error interrupt enable signal.
8 LAST_DMA_ REQ_SEL	Choosing the last DMA request condition. 0 fifo_full_level 1 hburst_length
7 DMA_FIELD1_ DONE_IE	When in interlace mode, field 1 done interrupt enable. 0 Interrupt disabled 1 Interrupt enabled
6 FIELD0_DONE_ IE	In interlace mode, field 0 means interrupt enabled. 0 Interrupt disabled 1 Interrupt enabled
5 BASEADDR_ SWITCH_SEL	CSI 2 base addresses switching method. When using this bit, BASEADDR_SWITCH_EN is 1. 0 Switching base address at the edge of the vsync 1 Switching base address at the edge of the first data of each frame
4 BASEADDR_ SWITCH_EN	When this bit is enabled, CSI DMA will switch the base address according to BASEADDR_SWITCH_SEL rather than atomically by DMA completed.
3 PARALLEL24_ EN	When input is parallel rgb888/yuv444 24bit, this bit can be enabled.
2 DEINTERLACE_ EN	This bit is used to select the output method When input is standard CCIR656 video. 0 Deinterlace disabled 1 Deinterlace enabled
-	This field is reserved. Reserved.

### 33.8.15 CSI Control Register 19 (CSI\_CSICR19)

This read/write register acts as an extension of the functionality of the CSI Control register 1

Address: 402B\_C000h base + 4Ch offset = 402B\_C04Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved																DMA_RFIFO_HIGHEST_FIFO_LEVEL															
W	Reserved																DMA_RFIFO_HIGHEST_FIFO_LEVEL															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### CSI\_CSICR19 field descriptions

Field	Description
31–8 -	This field is reserved.
DMA_RFIFO_HIGHEST_FIFO_LEVEL	This byte stores the highest FIFO level achieved by CSI FIFO timely and will be clear by writing 8'ff to it.

# Chapter 34

## Enhanced LCD Interface (eLCDIF)

### 34.1 Chip-specific eLCDIF information

### 34.2 Overview

The enhanced Liquid Crystal Display Interface (LCDIF) is a general purpose display controller

The LCDIF block supports the following:

- Displays that support moving pictures and require the RGB interface mode (DOTCLK interface).

The LCDIF provides fully programmable functionality to supported interfaces:

- Bus master interface to source frame buffer data for display refresh. This interface can also be used to drive data for "Smart" displays.
- DMA interface to manage data transfers between "Smart" displays and SoC.
- 8/16/18/24 bit LCD data bus support available depending on I/O mux options.
- Programmable timing and parameters for DOTCLK LCD interfaces.

### 34.3 External Signals

The following table describes the external signals of LCD:

**Table 34-2. LCD External Signals**

Signal	Description	Pad	Mode	Direction
LCD_CLK	Clock signal	GPIO_B0_00	ALT0	I
LCD_ENABLE	Enable signal	GPIO_B0_01	ALT0	IO
LCD_HSYNC	HSYNC signal	GPIO_B0_02	ALT0	I
LCD_VSYNC	VSYNC Signal	GPIO_B0_03	ALT0	I
LCD_DATA00	Data Signal	GPIO_B0_04	ALT0	IO
LCD_DATA01	Data Signal	GPIO_B0_05	ALT0	IO
LCD_DATA02	Data Signal	GPIO_B0_06	ALT0	IO
LCD_DATA03	Data Signal	GPIO_B0_07	ALT0	IO
LCD_DATA04	Data Signal	GPIO_B0_08	ALT0	IO
LCD_DATA05	Data Signal	GPIO_B0_09	ALT0	IO

## 34.4 Clocks

The following table describes the clock sources for LCDIF. Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information.

**Table 34-3. Clocks**

Clock Name	Clock Root	Description
apb_clk	ipg_clk_root	AXI Clock
pix_clk	lcdif_clk_root	Pixel Clock

## 34.5 Functional Description

[Bus Interface Mechanisms](#) through [Initializing the LCDIF](#), describe the internal pipeline for the LCDIF interfaces. Differences for each mode are then described in separate sections, as follows:

- [DOTCLK Interface](#)

LCDIF pin usage by interface mode is described in [LCDIF Pin Usage by Interface Mode](#).

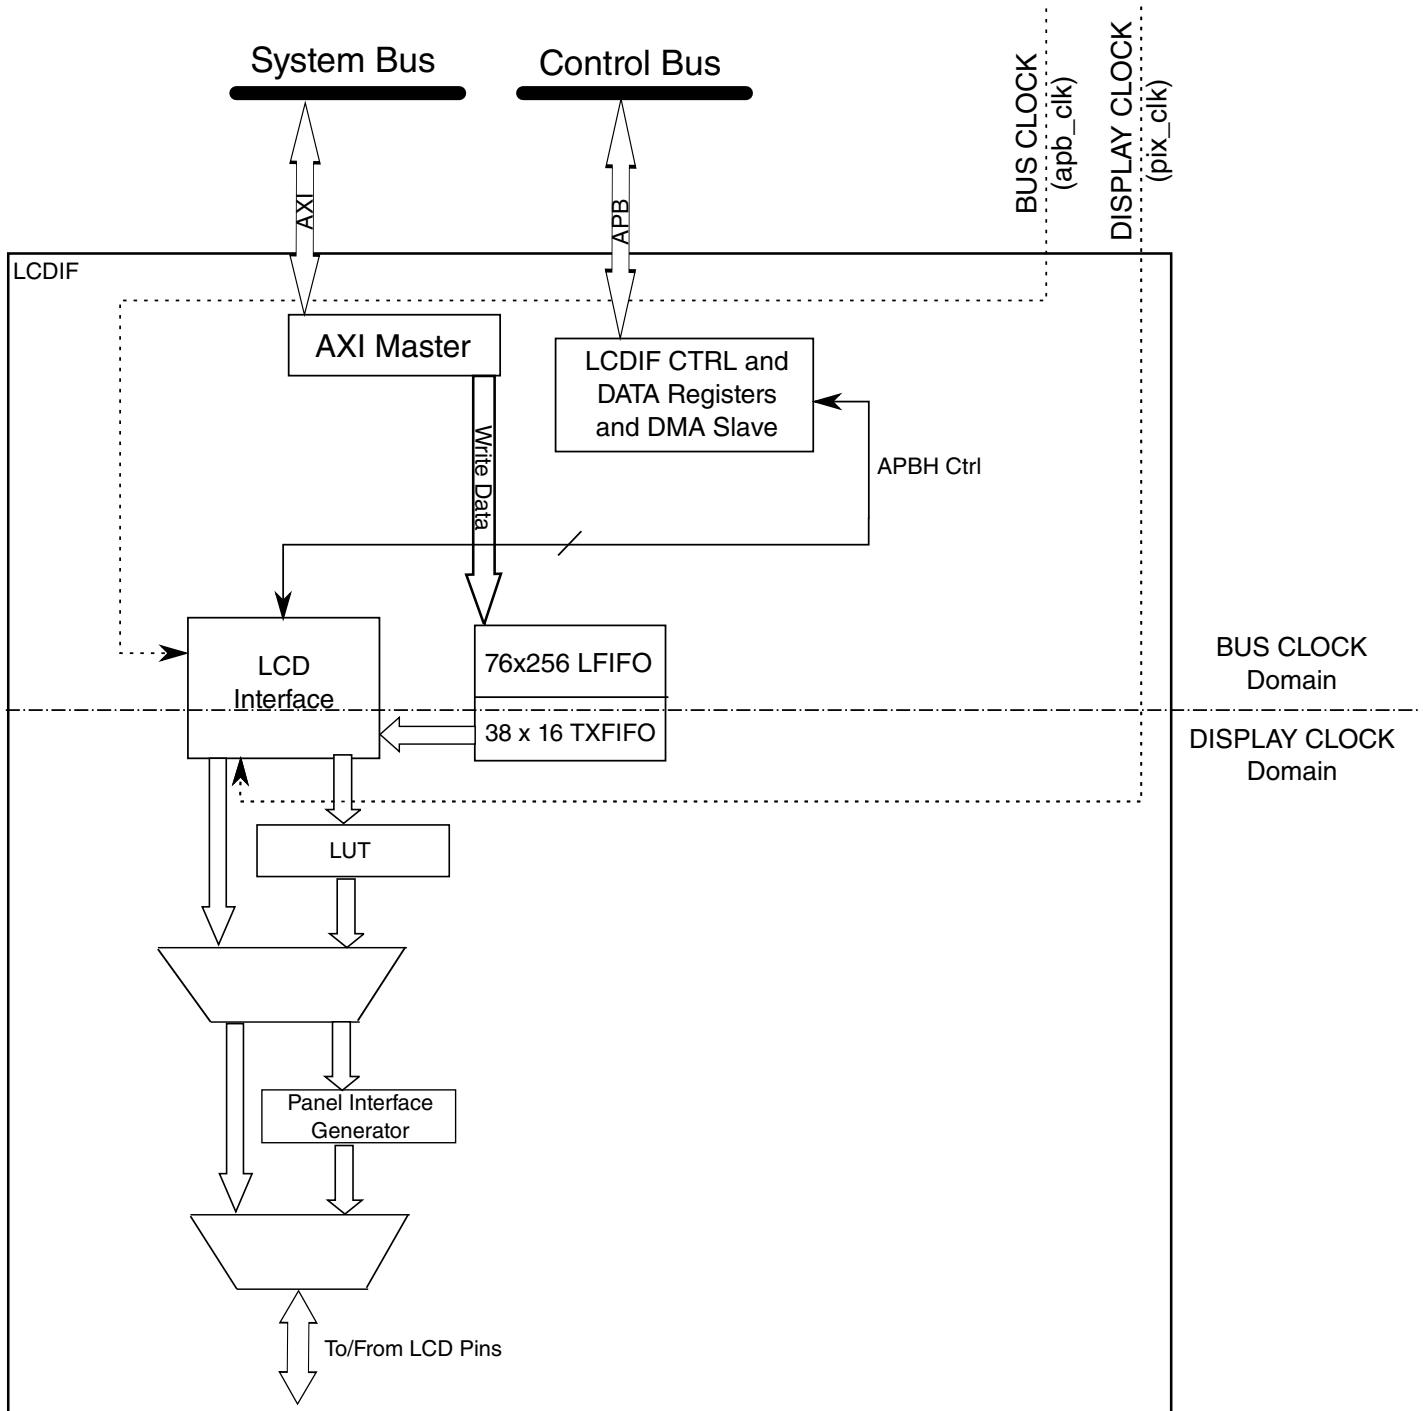

Figure 34-1. Top-Level Block Diagram of LCDIF subsystem

### 34.5.1 Bus Interface Mechanisms

The LCDIF module has memory-mapped control, data and status registers. It provides several interfaces to transfer data between the display and SoC.

The bus master interface is used to initiate the requests to transfer data from external memory to the display. It is completely autonomous, or no CPU intervention is required, to manage the cyclical nature of refreshing standard display types.

The DMA interface requires the SoC integrated APBDMA engine to manage data transfers on behalf of the LCDIF. APBDMA descriptor chains are created to manage control and data flow between the LCDIF and external display. This interface is typically used for "Smart" display types that integrate their own frame buffer and control interface. The APBDMA engine is used to reduce the CPU compute requirements to complete the display solution.

The host CPU executes display drivers to manage the display solution. The following sections describe the system bus interface mechanisms.

### 34.5.1.1 Bus Master Operation in Write/Display Modes

The LCDIF block has a bus master interface that initiates requests for data to drive the display. The LCDIF\_MASTER bit must be set to 1 to enable the bus master interface. Software should program all control registers required to transfer the frame sequence.

The DOTCLK mode is used to refresh the display at the desired refresh rate and resolution, and drive displays that don't integrate a display buffer memory. When the display is refreshed, the LCDIF will automatically update the LCDIF\_CUR\_BUF\_ADDR register with the value in LCDIF\_NEXT\_BUF\_ADDR at the end of current frame and start fetching the next frame from the new address. If the LCDIF\_NEXT\_BUF\_ADDR register was not updated within a frame refresh cycle, LCDIF will keep transmitting the last frame until a new value is programmed into that register.

### 34.5.1.2 System Bus Master Performance

The performance of the LCDIF block can be controlled by changing the burst length and the outstanding cycle issuing capability depending on the memory bandwidth requirements. Two fields in the LCDIF\_CTRL2 register will throttle system memory requests. The LCDIF\_CTRL2\_OUTSTANDING\_REQS field will control how many requests the LCDIF can have in flight on any given clock cycle. This should be programmed based on the expected system bus latency for returned read data. Also, the LCDIF\_CTRL2\_BURST\_LEN\_8 bit will set the number of 64 bit words requested for each LCDIF system bus request to either 8 or 16 QWORDS. Generally, 4 outstanding requests of length 16 will provide enough performance to drive any standard display

resolution. These configuration bits are intended to change the access pattern of the LCDIF to optimize system bus throughput when other system masters will contend for system memory resources.

### 34.5.1.3 DMA Operation in MPU Read Mode

Data can be transferred between an external display and the SoC using the APBDMA interface. This mode is enabled by setting the LCDIF\_MASTER bit to 0 and is typically used with "Smart" displays. The APBDMA module executes DMA descriptor chains to process the desired data flow sequence. The data can be either frame buffer data or display control data.

### 34.5.2 Write Data Path

LCDIF supports raster based frame buffers and there is no support for tiled buffers.

There are several options to accommodate endianness of display buffers in memory before the data is processed for the external display. The LCDIF\_CTRL[INPUT\_DATA\_SWIZZLE] field provides the following options for data word multiplexing:

```
00 (0): No swizzle (little-endian)
01 (1): Swap bytes 0 and 3, swap bytes 1 and 2 (big-endian)
10 (2): Swap half-words
11 (3): Swap bytes within each half-word
```

The LCDIF\_CTRL[WORD\_LENGTH] field indicates the input data/pixel format. LCDIF\_TRANSFER\_COUNT register denotes how much data is contained in each frame. The LCDIF\_TRANSFER\_COUNT[H\_COUNT] field indicates the number of pixels per line and LCDIF\_TRANSFER\_COUNT[V\_COUNT] indicates the total number of lines per frame. The LCDIF\_CTRL1[BYTE\_PACKING\_FORMAT] field can be used to specify which bytes within the 32-bit word are going to be valid. For example, if the entire 32-bit word is valid, LCDIF\_CTRL1[BYTE\_PACKING\_FORMAT] should be set to 0xF, if only lower 3 bytes of each word in the frame buffer are valid, then LCDIF\_CTRL1[BYTE\_PACKING\_FORMAT] should be set to 0x7.

The LCDIF\_CTRL[LCD\_DATABUS\_WIDTH] field suggests the width of the bus going to the display controller. There is an option to source all 32 bits of the input word and transfer it to the output I/O display interface. If the LCDIF\_CTRL[LCD\_DATABUS\_WIDTH] is not the same as LCDIF\_CTRL[WORD\_LENGTH], LCDIF will perform RGB to RGB color space conversion. For example, if the input frame has fewer bits per pixel than the display, as in a 16 bpp input frame going to 24 bpp LCD, LCDIF will pad the MSBs of each color to

the LSBs of the same color for each pixel. If the input frame has more bits per pixel than the display, for example, 24 bpp input frame going to 16 bpp LCD, LCDIF will drop the LSBs of each color channel to convert to the lower color depth. LCDIF also has the capability to support delta pixel displays by swizzling the R, G and B colors of each pixel in the odd and even lines of the frame separately by programming the LCDIF\_CTRL2[ODD\_LINE\_PATTERN] and the LCDIF\_CTRL2[EVEN\_LINE\_PATTERN] bit fields. This operation occurs after the RGB-to-RGB color space conversion operation.

The following list shows how the different input/output combinations can be obtained:

- LCDIF\_CTRL[WORD\_LENGTH]=1 indicates that the input is 8-bit data. Any combination of LCDIF\_CTRL1[BYTE\_PACKING\_FORMAT] is permissible.

Limitation: LCDIF\_TRANSFER\_COUNT[H\_COUNT] must be a multiple of the sum of BYTE\_PACKING\_FORMAT [3], BYTE\_PACKING\_FORMAT [2], BYTE\_PACKING\_FORMAT [1] and BYTE\_PACKING\_FORMAT [0].

LCDIF\_CTRL[LCD\_DATABUS\_WIDTH] must be 1, indicating an 8-bit data bus.

- LCDIF\_CTRL[WORD\_LENGTH]=0 implies the input frame buffer is RGB 16 bits per pixel. LCDIF\_CTRL[DATA\_FORMAT\_16\_BIT] field determines the pixels are RGB 555 or RGB 565.

Limitation: LCDIF\_CTRL1[BYTE\_PACKING\_FORMAT] should be 0x3 or 0xC if there is only one pixel per word. If there are two pixels per word, it should be 0xF and LCDIF\_TRANSFER\_COUNT[H\_COUNT] will be restricted to be a multiple of 2 pixels.

- LCDIF\_CTRL[WORD\_LENGTH]=2 indicates that input frame buffer is RGB 18 bits per pixel, that is, RGB 666. The valid RGB values can be left-aligned or right-aligned within a 32-bit word. The alignment of the valid 18 bits within a word is indicated by the LCDIF\_CTRL[DATA\_FORMAT\_18\_BIT] bit.

Limitation: LCDIF\_CTRL1[BYTE\_PACKING\_FORMAT] can be 0x7, 0xE or 0xF. Packed pixels are not supported in this case.

LCDIF\_TRANSFER\_COUNT[H\_COUNT] can be any number.

- LCDIF\_CTRL[WORD\_LENGTH]=3 indicates that the input frame-buffer is RGB 24 bits per pixel (RGB 888). If LCDIF\_CTRL1[BYTE\_PACKING\_FORMAT] is 0x7, it indicates that there is only one pixel per 32-bit word and there is no restriction on LCDIF\_TRANSFER\_COUNT[H\_COUNT]. This is also the option that provides 32 bit output depending on the I/O muxing options available. The fourth byte, or bits [31:24], and connected to the I/Os if this muxing is available in the chip package.

## Functional Description

Limitation: If LCDIF\_CTRL1[BYTE\_PACKING\_FORMAT] is 0xF, it indicates that the pixels are packed, that is, there are 4 pixels in 3 words or 12 bytes and LCDIF\_TRANSFER\_COUNT[H\_COUNT] must be a multiple of 4 pixels.

After the RGB to RGB color space conversions, there is one more opportunity to swizzle the data before sending it out to the display or the encoder. This can be done with the LCDIF\_CTRL[CSC\_DATA\_SWIZZLE] field, and it provides the same options as the LCDIF\_CTRL[INPUT\_DATA\_SWIZZLE] register.

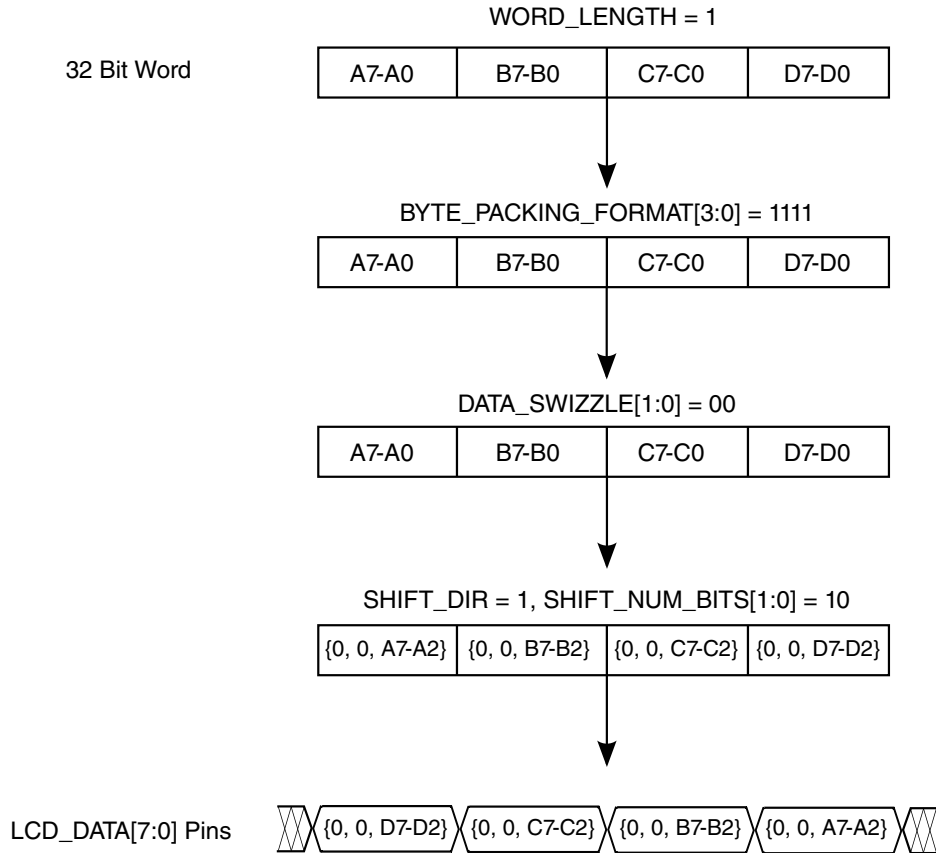

Finally, there is an option to shift the output data before sending it out to the display. This is done based on the LCDIF\_CTRL[SHIFT\_DIR] and LCDIF\_CTRL[SHIFT\_NUM\_BITS] fields.

**Figure 34-2. General Operations in Write Data Path**

The examples in the following figures illustrate some different combinations of register programming for write mode. Assume that the data transferred over the system bus within a 32 bit word is organized as {A7-A0, B7-B0, C7-C0, D7-D0} in 8-bit mode and {A15-A0, B15-B0} in 16-bit mode.

In this example, all 32 bits of the input word are transferred out over an 8 bit display bus. Each byte within the 32 bit word is shifted to the right with zeros appended to bits D[7:6]. The input data bits [7:2] are shifted to the right by 2 bits and presented on the D[5:0].

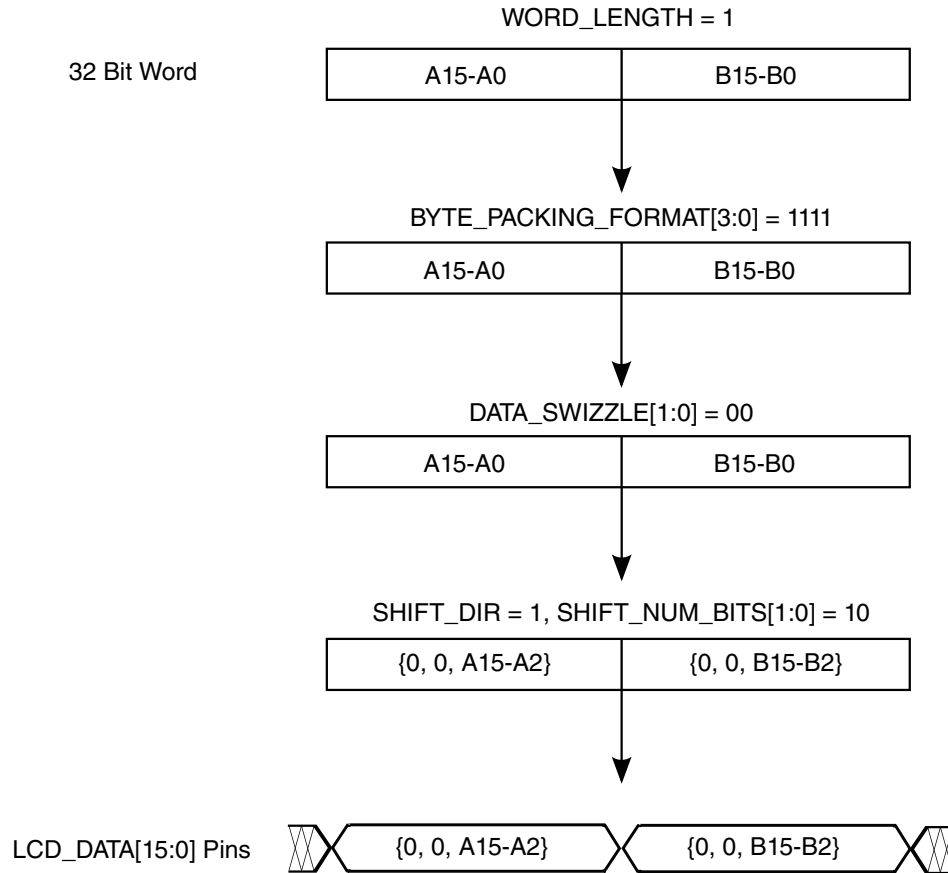

**Figure 34-3. Register programming for write mode**

In this 8 bit display interface example, one byte of the input word is deleted and not transferred over the external 8 bit display interface. This mode could be used to transfer 24bpp pixels over the 8 bit interface. In this case, the 4th unused byte is not transferred.

**Figure 34-4. Register programming for write mode**

The following example uses a 16 bit display interface. Each 16 bit half word is shifted to the right by two bits with zeros appended to the most significant two bits.

**Figure 34-5. Register programming for write mode**

This example indicates how an unpacked frame buffer can be sourced for display. Only a single 16-bit half word within the 32-bit word is transferred out via the 16-bit display bus.

**Figure 34-6. Register programming for write mode**

### 34.5.3 LCDIF Interrupts

LCDIF supports a number of interrupts to aid controlling and status reporting of the block.

All the interrupts have individual mask bits for enabling or disabling each of them. They all get funneled through a single interrupt line connected to the interrupt collector (ICOLL).

The following list describes the different interrupts supported by LCDIF:

- Underflow interrupt is asserted when the clock domain crossing FIFO (TXFIFO) becomes empty but the block is in active display portion during that time. Software should take corrective action to make sure that this does not happen.
- In the bus master mode, the overflow interrupt will be asserted if the block has requested more data than it's FIFOs could hold.
- Cur\_frame\_done interrupt occurs at the end of every frame .

## 34.5.4 Initializing the LCDIF

This section describes write modes.

### 34.5.4.1 Write Modes

The following initialization steps are common to all LCDIF write modes of operation before entering any particular mode.

Initialization steps:

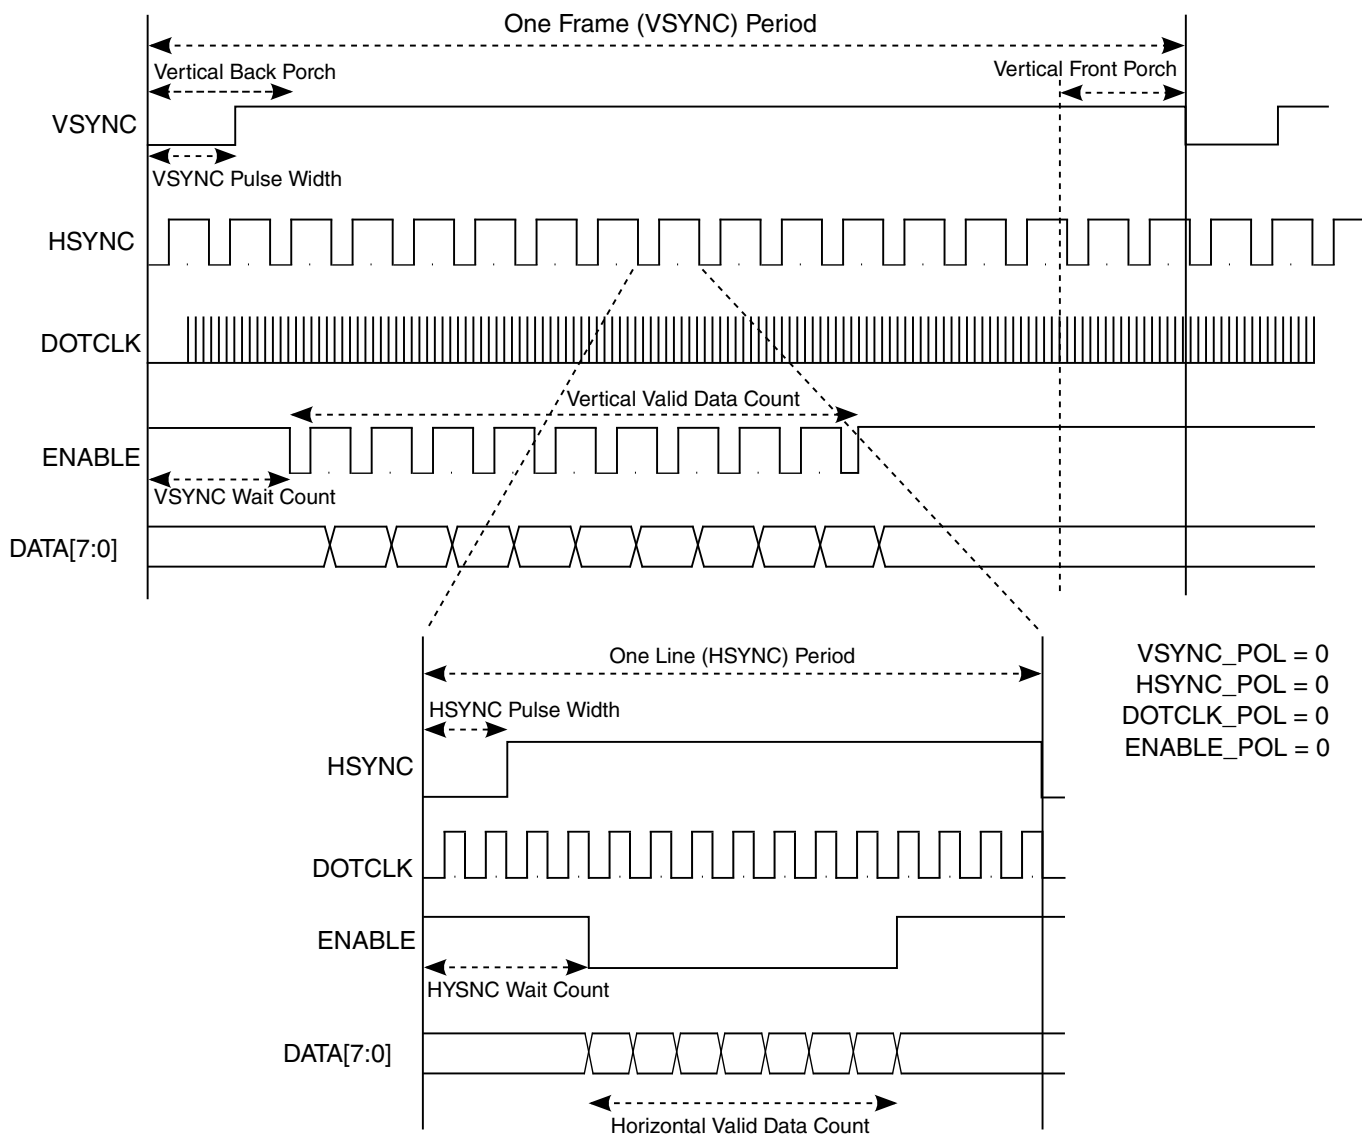

1. Configure the external I/Os to correctly interface the external display, when required.
2. Start the DISPLAY CLOCK (pix\_clk) clock and set the appropriate frequency by programming the registers in CCM.
3. Start the BUS CLOCK (apb\_clk) and set the appropriate frequency by programming the registers in CCM.
4. Bring the LCDIF out of soft reset and disable the clock gate bit.
5. Set the transfer mode of operation to bus master. The LCDIF\_CTRL[MASTER] bit determines the transfer mode selected. Bus master (LCDIF\_CTRL[MASTER] =1), APBDMA is the transfer mode to select.
6. Set the LCDIF\_CTRL[INPUT\_DATA\_SWIZZLE] according to the endianness of the LCD controller. Also, set the LCDIF\_CTRL[DATA\_SHIFT\_DIR] and LCDIF\_CTRL[SHIFT\_NUM\_BITS] if it is required to shift the data left or right before it is output.
7. Set the LCDIF\_CTRL[WORD\_LENGTH] field appropriately: 0 = 16-bit input, 1 = 8-bit input, 2 = 18-bit input, 3 = 24/32-bit input. Also, select the correct 16/18/24 bit data format with the corresponding fields in LCDIF\_CTRL register.
8. Set the LCDIF\_CTRL1[BYTE\_PACKING\_FORMAT] field according to the input frame.
9. Set the LCDIF\_CTRL[LCD\_DATABUS\_WIDTH] appropriately: 0 = 16-bit output, 1 = 8-bit output, 2 = 18-bit output, 3 = 24/32-bit output.
10. Enable the necessary IRQs.

## 34.5.5 DOTCLK Interface

The DOTCLK interface is another mode used in moving picture displays.

It includes the VSYNC, HSYNC, DOTCLK and (optional) ENABLE signals. The interface is popularly called the RGB interface if the ENABLE signal is present.

## Functional Description

**Figure 34-7. DOTCLK protocol with programmable parameters**

The DOTCLK mode writes data at high speed to the LCD, and the display operation is synchronized with the VSYNC, HSYNC, ENABLE and DOTCLK signals. The polarities, periods and pulse-widths of the sync signals are programmable using the LCDIF\_VDCTRL0-4 registers. The units for the VSYNC signal must be number of horizontal lines and can be selected using the VSYNC\_PULSE\_WIDTH\_UNIT and VSYNC\_PERIOD\_UNIT bit fields. The VERTICAL\_WAIT\_CNT is by default given the same unit as the VSYNC\_PERIOD. The DISPLAY CLOCK (pix\_clk) frequency is managed by the CCM.

In DOTCLK mode, LCDIF\_CTRL\_BYPASS\_COUNT bit must be set to 1. To end the current transfer, the software should make the DOTCLK\_MODE bit 0, so that all data that is currently in the LCDIF LFIFO and TXFIFO is transmitted. Once that transfer is complete, the block will automatically clear the RUN bit and issue the cur\_frame\_done interrupt.

### 34.5.5.1 Code Example

The following code shows an example for programming a 320x240 display.

#### NOTE

Setting up the display must be done via SPI.

```
// Note: Common initialization steps in Initializing the LCDIF must also be
// executed along with the following code
BF_CS1 (LCDIF_CTRL, DOTCLK_MODE, 1);
BF_CS1 (LCDIF_CTRL, BYPASS_COUNT, 1); //Always for DOTCLK mode
BF_CS1 (LCDIF_VDCTRL0, VSYNC_OEB, 0); //Vsync is always an output in the DOTCLK mode
BF_CS4 (LCDIF_VDCTRL0, VSYNC_POL, 0, HSYNC_POL, 0, DOTCLK_POL, 0, ENABLE_POL, 0);
BF_CS1 (LCDIF_VDCTRL0, ENABLE_PRESENT, 1);
BF_CS2 (LCDIF_VDCTRL0, VSYNC_PERIOD_UNIT, 1, VSYNC_PULSE_WIDTH_UNIT, 1);
BF_CS1 (LCDIF_VDCTRL0, VSYNC_PULSE_WIDTH, 2);
BF_CS1 (LCDIF_VDCTRL1, VSYNC_PERIOD, 280);
BF_CS2 (LCDIF_VDCTRL2, HSYNC_PULSE_WIDTH, 10, HSYNC_PERIOD, 360); //Assuming
// LCD_DATABUS_WIDTH is 24bit
BF_CS2 (LCDIF_VDCTRL3, VSYNC_ONLY, 0);
BF_CS2 (LCDIF_VDCTRL3, HORIZONTAL_WAIT_CNT, 20, VERTICAL_WAIT_CNT, 20);
BF_CS1 (LCDIF_VDCTRL4, DOTCLK_H_VALID_DATA_CNT, 320); //Note that DOTCLK_V_VALID_DATA_CNT is
//implicitly assumed to be HW_LCDIF_TRANSFER_COUNT_V_COUNT
BF_CS1 (LCDIF_VDCTRL4, SYNC_SIGNALS_ON, 1);
BF_CS1 (LCDIF_CTRL, RUN, 1);
```

To stop the transfer completely, the ideal way is to make DOTCLK\_MODE = 0. In that case, the block will transmit the contents in the FIFO and reset the RUN bit.

### 34.5.6 LUT

The Lookup Table (LUT) is used to expand the 8 bits pixel to 24 bits pixel before output to external displayer. This module is used when input data from memory is 8-bits in width under limited bandwidth system and external displayer has a 24 bits requirement.

There are two 256x24 bits LUT memory in LCDIF module in case of changing LUT during active display. When using LUT function, it should be initialized through single PIO register writing first. Writing data to register LCDIF\_LUT0\_DATA will trigger storing data to lut0 memory and increase the lut0 memory address LCDIF\_LUT0\_ADDR automatically. Writing data again to register LCDIF\_LUT0\_DATA will store the data to memory and increase the memory address accordingly. The same operation is performed while writing to LCDIF\_LUT1\_DATA and LCDIF\_LUT1\_ADDR.

After initialization, LCDIF\_CUR\_BUF\_ADDR bit 0 determines which LUT is used during active display.

Lastly, when there is active display, it will use the lowest 8 bits LCDIF data as LUT address and output the 24 bits from the lookup table.

### 34.5.7 Panel Interface Generator (Pigeon Mode)

There are several panel interface signal outputs (CLK signal not included), each of them with dedicated timing purpose as default. This is called "Legacy Mode". Pigeon Mode is a timing mode which can be independently enabled on any of the timing signals, with a unified flexible configuration. Signals within pigeon mode can be programmed into any supported signals, and are interchangeable. The following are the legacy timing signals which support pigeon mode:

- PIGEON[00] – LCD\_DATA16
- PIGEON[01] – LCD\_DATA17
- PIGEON[02] – LCD\_DATA18
- PIGEON[03] – LCD\_DATA19
- PIGEON[04] – LCD\_DATA20
- PIGEON[05] – LCD\_DATA21
- PIGEON[06] – LCD\_DATA22
- PIGEON[07] – LCD\_DATA23
- PIGEON[08] – LCD\_ENABLE
- PIGEON[09] – LCD\_HSYNC
- PIGEON[10] – LCD\_VSYNC
- PIGEON[11] – LCD\_CLK

Each pigeon signal has one local counter with a configurable start point and incremental condition. It will be compared to configuration register value for signal assertion/de-assertion control, plus delta offset for data alignment and other options like polarity/logic operation. A detailed running scenario is as follows:

1. Start local counter on the MASK rising edge (reference point/start point)
2. Increment on event selected through INC\_SEL
3. Count and match SET\_CNT: assert signal, reset counter (SET\_CNT==0 means assert immediately on MASK's rising edge)
4. Count and match CLR\_CNT: de-assert signal, stop counter (CLR\_CNT==0 means de-assert on MASK's falling edge)

#### **NOTE**

When local counter is running, further changes to MASK are not cared unless CLR\_CNT==0

MASK is the start point for local counter created using a combination any of the options (ANDed) from below:

1. STATE\_MASK= (FS|FB|FD|FE) AND (LS|LB|LD|LE)

In this case you have 8 bits to select in which vertical/horizontal state your counter starts ticking. This is the most common use-case because timing signals generally relate to scan states.

For example, for a line timing signal start on Line Begin phase during Frame Begin/ Frame Data lines, use the configuration below:

**Table 34-4. State Mask Combinations**

STATE_MASK	LS	LB=1	LD	LE
FS				
FB=1		X		
FD=1		X		
FE				

2. MASK\_CNT/MASK\_CNT\_SEL (global counter)

Sometimes a more accurate reference point is required, such as "line 20 in a frame", or "line 12 in Frame Begin state" or "pixel 23 in LD phase". For such use-cases, several Global Counters shared by all pigeons are provided. Global counter type (line counter/frame counter/state counter, etc.) is selected using MASK\_CNT\_SEL, when global counter matches the MASK\_CNT value. The pigeon local counter will start ticking.

3. Use another pigeon signal as mask (SIG\_LOGIC=MASK)

For some tightly coupled signals it is possible to use one as a reference to generate another.

INC\_SEL- select local counter tick event

- a. pclk - pixel clk
- b. line - line start pulse
- c. frame - frame start pulse
- d. another - another pigeon signal

OFFSET- offset on pclk basis: Some signals need to come out slightly earlier or later than programmed. For example, the CE type signal usually aligns with the Line Data phase, but some panels need it as one cycle pulse before Line Data. The user can set OFFSET to a negative value to achieve this.

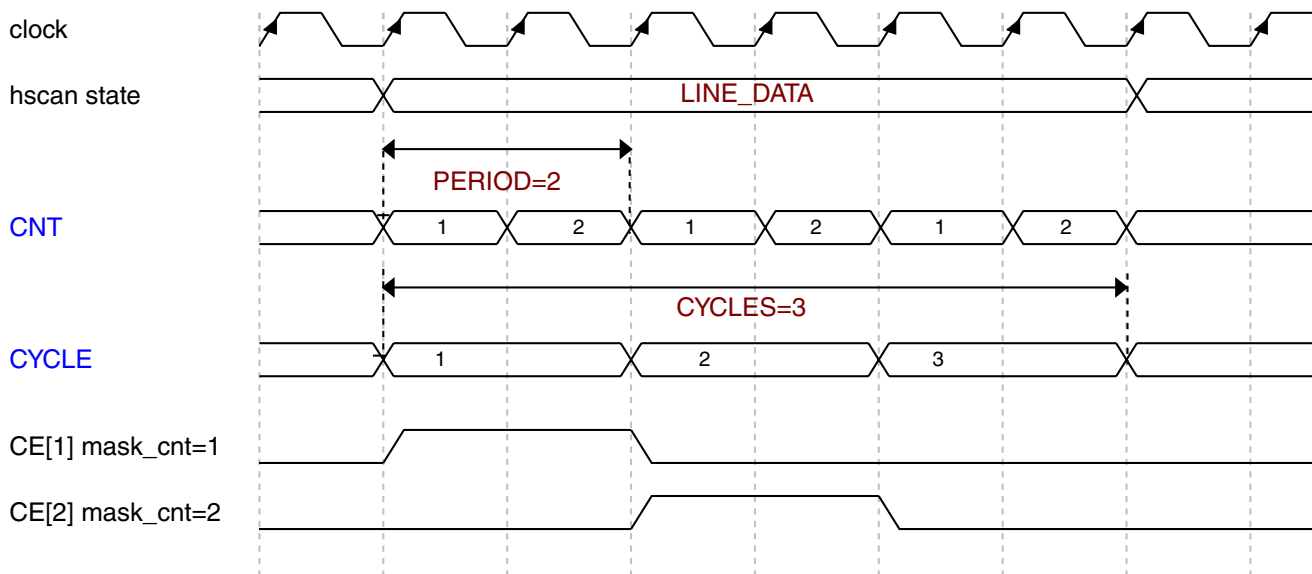

Global counters (selectable through MASK\_CNT\_SEL):

## Functional Description

- HCNT / VCNT : normal plck counter / line counter
- HSTATE\_CNT / VSTATE\_CNT: similar to above, but reset when state changes
- HSTATE\_CYCLE / VSTATE\_CYCLE: (see figure below for definition of CYCLE/ PERIOD/CNT)

Some panels have multiple Gate Drivers/Source Drivers, so Frame Data / Line Data state may be further split to match each driver, and signals such as CE[n] are only valid during part n of Line Data. For such signals, use LCDIF\_PIGEON\_CTRL[\*\_PERIOD] to specify PERIOD where CNT is reset and CYCLE is included. Then the user can select CYCLE as MASK\_CNT to generate mask for CE[n].

- FRAME\_CNT / FRAME\_CYCLE (only for frame-crossing signals): frame cycle counter doesn't have a reset condition; use LCDIF\_PIGEON\_CTRL1[FRAME\_CNT\_CYCLES] to reset it.

**Figure 34-8. Definition of CNT, CYCLE, PERIOD**

The following are register settings for the figure above:

- LCDIF\_PIGEON\_CTRL0[LD\_PERIOD]=2
- MASK\_CNT\_SEL = 1 // HSTATE\_CYCLE
- MASK\_CNT = 1 // CE[1]
- MASK\_CNT = 2 // CE[2]

## 34.5.8 LCDIF Pin Usage by Interface Mode

The following tables detail how the LCDIF level interface pins are used based on the desired mode of operation. The chip level I/Os should also be configured to be consistent with the desired LCDIF operating mode.

### NOTE

There is an option to internally mux the HSYNC, DOTCLK and ENABLE signals in the DOTCLK mode by setting the MUX\_SYNC\_SIGNALS bit in the VDCTRL0 register.

**Table 34-5. Pin use in DOTCLK Mode**

PIN NAME	8-bit DOTCLK LCD IF	16-bit DOTCLK LCD IF	18-bit DOTCLK LCD IF	24-bit DOTCLK LCD IF

## 34.6 Behavior During Reset

BUS CLOCK (apb\_clk) and DISPLAY CLOCK (pix\_clk) must be running before making any changes to SFTRST or CLKGATE bits.

A soft reset (SFTRST) can take multiple clock periods to complete, so do not set CLKGATE when setting SFTRST.

The reset process gates the clocks automatically.

## 34.7 LCDIF Memory Map/Register Definition

Some of the LCDIF registers (XXX\_SET, XXX\_CLR, and XXX\_TOG) allow direct bit field masking and access.

- When writing 1 to XXX\_SET bit fields, these registers allow setting the masked 1 bit fields, while keeping unchanged all bit fields which remain on 0 logic state.

- When writing 1 to XXX\_CLR bit fields, these registers allow clearing the masked 1 bit fields, while keeping unchanged all other bit fields which remained on 0 logic state.
- When writing 1 to XXX\_TOG bit fields, these registers allow inverting the logic state of all masked 1 bit fields, while they keep unchanged the remaining bit fields which were kept on 0 logic state.

## LCDIF Hardware Register Format Summary

### LCDIF memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
402B_8000	LCDIF General Control Register (LCDIF_CTRL)	32	R/W	C000_0000h	<a href="#">34.7.1/1969</a>

### 34.7.1 LCDIF General Control Register (LCDIF\_CTRLn)

The LCD Interface Control Register provides overall control of the LCDIF block. The LCDIF Control Register provides a variety of control functions to the programmer. These functions allow the interface to be very flexible to work with a variety of LCD controllers, and to minimize overhead and increase performance of LCD programming. The register has been organized such that switching between the different LCD modes can be done with minimum PIO writes.

Address: 402B\_8000h base + 0h offset + (4d × i), where i=0d to 3d

**LCDIF\_CTRLn field descriptions**

Field	Description
31 SFTRST	This bit must be set to zero to enable normal operation of the LCDIF. When set to one, it forces a block level reset.
30 CLKGATE	This bit must be set to zero for normal operation. When set to one it gates off the clocks to the block.
29 -	Reserved
28 -	This field is reserved. Reserved

Table continues on the next page...

## LCDIF\_CTRLn field descriptions (continued)

Field	Description
27 -	This field is reserved. Reserved
26 DATA_SHIFT_ DIR	Use this bit to determine the direction of shift of transmit data. 0x0 <b>TXDATA_SHIFT_LEFT</b> — Data to be transmitted is shifted LEFT by SHIFT_NUM_BITS bits. 0x1 <b>TXDATA_SHIFT_RIGHT</b> — Data to be transmitted is shifted RIGHT by SHIFT_NUM_BITS bits.
25–21 SHIFT_NUM_ BITS	The data to be transmitted is shifted left or right by this number of bits.
20 -	This field is reserved. Reserved
19 BYPASS_ COUNT	When this bit is 0, it means that LCDIF will stop the block operation and turn off the RUN bit after the amount of data indicated by the LCDIF_TRANSFER_COUNT register has been transferred out. When this bit is set to 1, the block will continue normal operation indefinitely until it is told to stop. This bit must be 0 in MPU and VSYNC modes, and must be 1 in DOTCLK and DVI modes of operation.
18 -	This field is reserved. Reserved
17 DOTCLK_MODE	Set this bit to 1 to make the hardware go into the DOTCLK mode, i.e. VSYNC/HSYNC/DOTCLK/ENABLE interface mode. ENABLE is optional, selected by the ENABLE_PRESENT bit. Toggle this bit from 1 to 0 to make the hardware go out of DOTCLK mode after completing all data transfer and deasserting the RUN bit.
16 -	This field is reserved. Reserved
15–14 INPUT_DATA_ SWIZZLE	This field specifies how to swap the bytes fetched by the bus master interface. The swizzle function is independent of the WORD_LENGTH bit. The supported swizzle configurations are: 0x0 <b>NO_SWAP</b> — No byte swapping.(Little endian) 0x0 <b>LITTLE_ENDIAN</b> — Little Endian byte ordering (same as NO_SWAP). 0x1 <b>BIG_ENDIAN_SWAP</b> — Big Endian swap (swap bytes 0,3 and 1,2). 0x1 <b>SWAP_ALL_BYTES</b> — Swizzle all bytes, swap bytes 0,3 and 1,2 (aka Big Endian). 0x2 <b>HWD_SWAP</b> — Swap half-words. 0x3 <b>HWD_BYTE_SWAP</b> — Swap bytes within each half-word.
13–12 CSC_DATA_ SWIZZLE	This field specifies how to swap the bytes after the data has been converted into an internal representation of 24 bits per pixel and before it is transmitted over the LCD interface bus. The data is always transmitted with the least significant byte/hword (half word) first after the swizzle takes place. So, INPUT_DATA_SWIZZLE takes place first on the incoming data, and then CSC_DATA_SWIZZLE is applied. The swizzle function is independent of the WORD_LENGTH or the LCD_DATABUS_WIDTH fields. If RGB_TO_YCRCB422_CSC bit is set, the swizzle occurs on the Y, Cb, Cr values. The supported swizzle configurations are: 0x0 <b>NO_SWAP</b> — No byte swapping.(Little endian) 0x0 <b>LITTLE_ENDIAN</b> — Little Endian byte ordering (same as NO_SWAP). 0x1 <b>BIG_ENDIAN_SWAP</b> — Big Endian swap (swap bytes 0,3 and 1,2). 0x1 <b>SWAP_ALL_BYTES</b> — Swizzle all bytes, swap bytes 0,3 and 1,2 (aka Big Endian). 0x2 <b>HWD_SWAP</b> — Swap half-words. 0x3 <b>HWD_BYTE_SWAP</b> — Swap bytes within each half-word.
11–10 LCD_DATABUS_ WIDTH	LCD Data bus transfer width. 0x0 <b>16_BIT</b> — 16-bit data bus mode.

Table continues on the next page...

## LCDIF\_CTRLn field descriptions (continued)

Field	Description
	0x1 <b>8_BIT</b> — 8-bit data bus mode. 0x2 <b>18_BIT</b> — 18-bit data bus mode. 0x3 <b>24_BIT</b> — 24-bit data bus mode.
9–8 WORD_LENGTH	Input data format. 0x0 <b>16_BIT</b> — Input data is 16 bits per pixel. 0x1 <b>8_BIT</b> — Input data is 8 bits wide. 0x2 <b>18_BIT</b> — Input data is 18 bits per pixel. 0x3 <b>24_BIT</b> — Input data is 24 bits per pixel.
7 -	This field is reserved. Reserved
6 ENABLE_PXP_ HANDSHAKE	If this bit is set and LCDIF_MASTER bit is set, the LCDIF will act as bus master and the handshake mechanism between LCDIF and PXP will be turned on. If LCDIF_MASTER bit is not set, this bit becomes a don't care.
5 MASTER	Set this bit to make the LCDIF act as a bus master. If this bit is reset, the LCDIF will support APBDMA or PIO mode.
4 RSRVD0	This field is reserved. Reserved bits. Write as 0.
3 DATA_ FORMAT_16_ BIT	When this bit is 1 and WORD_LENGTH = 0, it implies that the 16-bit data is in ARGB555 format. When this bit is 0 and WORD_LENGTH = 0, it implies that the 16-bit data is in RGB565 format. When WORD_LENGTH is not 0, this bit does not care.
2 DATA_ FORMAT_18_ BIT	Used only when WORD_LENGTH = 2, i.e. 18-bit. 0x0 <b>LOWER_18_BITS_VALID</b> — Data input to the block is in 18 bpp format, such that lower 18 bits contain RGB 666 and upper 14 bits do not contain any useful data. 0x1 <b>UPPER_18_BITS_VALID</b> — Data input to the block is in 18 bpp format, such that upper 18 bits contain RGB 666 and lower 14 bits do not contain any useful data.
1 DATA_ FORMAT_24_ BIT	Used only when WORD_LENGTH = 3, i.e. 24-bit. Note that this applies to both packed and unpacked 24-bit data. 0x0 <b>ALL_24_BITS_VALID</b> — Data input to the block is in 24 bpp format, such that all RGB 888 data is contained in 24 bits. 0x1 <b>DROP_UPPER_2_BITS_PER_BYTE</b> — Data input to the block is actually RGB 18 bpp, but there is 1 color per byte, hence the upper 2 bits in each byte do not contain any useful data, and should be dropped.
0 RUN	When this bit is set by software, the LCDIF will begin transferring data between the SoC and the display. This bit must remain set until the operation is complete.

### 34.7.2 LCDIF General Control1 Register (LCDIF\_CTRL1n)

The LCDIF Control Register provides overall control of the LCDIF block.

The LCDIF Control1 Register provides additional programming to the LCDIF. It implements some bits which are unlikely to change often in a particular application. It also carries interrupt-related bits which are common across more than one mode of operation.

## LCDIF Memory Map/Register Definition

Address: 402B\_8000h base + 10h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

### LCDIF\_CTRL1n field descriptions

Field	Description
31 IMAGE_DATA_SELECT	Command Mode MIPI image data select bit. This bit will control MIPI DSI SYS_ADDR[1]. This bit should only be changed when RUN is 0.
30 CS_OUT_SELECT	This bit is CS0/CS1 valid select signals. When set 0x0, LCDIF_CSn0 output valid, and LCSIF_CSn1 will always output 1. When set to 0x1, LCDIF_CSn1 output valid, and LCSIF_CSn0 will always output 1.
29–28 -	This field is reserved. Reserved bits. Write as 0.
27 -	This field is reserved. Reserved.
26 BM_ERROR_IRQ_EN	This bit is set to enable bus master error interrupt in the LCDIF master mode.
25 BM_ERROR_IRQ	This bit is set to indicate that an interrupt is requested by the LCDIF block. This bit is cleared by software by writing a one to its SCT clear address. This bit will be set when the LCDIF is in master mode and an error response was returned by the slave.  0x0 <b>NO_REQUEST</b> — No Interrupt Request Pending. 0x1 <b>REQUEST</b> — Interrupt Request Pending.
24 RECOVER_ON_UNDERFLOW	Set this bit to enable the LCDIF block to recover in the next field/frame if there was an underflow in the current field/frame.

Table continues on the next page...

## LCDIF\_CTRL1n field descriptions (continued)

Field	Description
23 INTERLACE_ FIELDS	Set this bit if it is required that the LCDIF block fetches odd lines in one field and even lines in the other field. It will work only in LCDIF_MASTER is set to 1.
22 START_ INTERLACE_ FROM_ SECOND_FIELD	The default is to grab the odd lines first and then the even lines. Set this bit if it is required to grab the even lines first and then the odd lines. (Line numbers start from 1, so odd lines are 1,3,5,etc. and even lines are 2,4,6, etc.)
21 FIFO_CLEAR	Set this bit to clear all the data in the latency FIFO (LFIFO), TXFIFO and the RXFIFO.
20 IRQ_ON_ ALTERNATE_ FIELDS	If this bit is set, the LCDIF block will assert the cur_frame_done interrupt only on alternate fields, otherwise it will issue the interrupt on both odd and even field. This bit is mostly relevant if INTERLACE_FIELDS is set.
19–16 BYTE_ PACKING_ FORMAT	This bitfield is used to show which data bytes in a 32-bit word are valid. Default value 0xf indicates that all bytes are valid. For 8-bit transfers, any combination in this bitfield will mean valid data is present in the corresponding bytes. In the 16-bit mode, a 16-bit half-word is valid only if adjacent bits [1:0] or [3:2] or both are 1. A value of 0x0 will mean that none of the bytes are valid and should not be used. For example, set the bit field value to 0x7 if the display data is arranged in the 24-bit unpacked format (A-R-G-B where A value does not have to be transmitted).
15 OVERFLOW_ IRQ_EN	This bit is set to enable an overflow interrupt in the TXFIFO in the write mode.
14 UNDERFLOW_ IRQ_EN	This bit is set to enable an underflow interrupt in the TXFIFO in the write mode.
13 CUR_FRAME_ DONE_IRQ_EN	This bit is set to 1 enable an interrupt every time the hardware enters in the vertical blanking state.
12 VSYNC_EDGE_ IRQ_EN	This bit is set to enable an interrupt every time the hardware encounters the leading VSYNC edge in the VSYNC and DOTCLK modes, or the beginning of every field in DVI mode.
11 OVERFLOW_ IRQ	This bit is set to indicate that an interrupt is requested by the LCDIF block. This bit is cleared by software by writing a one to its SCT clear address. A latency FIFO (LFIFO) overflow in the write mode (MPU/VSYNC/DOTCLK/DVI mode) was detected, data samples have been lost.  0x0 <b>NO_REQUEST</b> — No Interrupt Request Pending. 0x1 <b>REQUEST</b> — Interrupt Request Pending.
10 UNDERFLOW_ IRQ	This bit is set to indicate that an interrupt is requested by the LCDIF block. This bit is cleared by software by writing a one to its SCT clear address. A TXFIFO underflow in the write mode (MPU/VSYNC/DOTCLK/DVI mode) was detected. Could produce an error in the DOTCLK / DVI modes.  0x0 <b>NO_REQUEST</b> — No Interrupt Request Pending. 0x1 <b>REQUEST</b> — Interrupt Request Pending.
9 CUR_FRAME_ DONE_IRQ	This bit is set to indicate that an interrupt is requested by the LCDIF block. This bit is cleared by software by writing a one to its SCT clear address. It indicates that the hardware has completed transmitting the current frame and is in the vertical blanking period in the DOTCLK/DVI modes. In the MPU and VSYNC modes, this IRQ is asserted at the end of the data transfer indicated by LCDIF_TRANSFER_COUNT register.

Table continues on the next page...

**LCDIF\_CTRL1n field descriptions (continued)**

Field	Description
	0x0 <b>NO_REQUEST</b> — No Interrupt Request Pending. 0x1 <b>REQUEST</b> — Interrupt Request Pending.
8 VSYNC_EDGE_ IRQ	This bit is set to indicate that an interrupt is requested by the LCDIF block. This bit is cleared by software by writing a one to its SCT clear address. It is set whenever the leading VSYNC edge is detected in the VSYNC and DOTCLK modes. In the DVI mode, it is asserted every time the block enters a new field.  0x0 <b>NO_REQUEST</b> — No Interrupt Request Pending. 0x1 <b>REQUEST</b> — Interrupt Request Pending.
7–3 RSRVD0	This field is reserved. Reserved bits. Write as 0.
2 -	This field is reserved. Reserved
1 -	This field is reserved. Reserved.
0 -	This field is reserved. Reserved.

**34.7.3 LCDIF General Control2 Register (LCDIF\_CTRL2n)**

The LCDIF Control Register provides overall control of the LCDIF block.

The LCDIF Control2 Register provides additional programming to the LCDIF. It implements some bits which are unlikely to change often in a particular application.

Address: 402B\_8000h base + 20h offset + (4d × i), where i=0d to 3d

## LCDIF\_CTRL2n field descriptions

Field	Description
31–24 RSRVD5	This field is reserved. Reserved bits. Write as 0.
23–21 OUTSTANDING_REQS	This bitfield indicates the maximum number of outstanding transactions that LCDIF should request when it is acting as a bus master. Default is 2 outstanding transactions.  0x0 <b>REQ_1</b> — 0x1 <b>REQ_2</b> — 0x2 <b>REQ_4</b> — 0x3 <b>REQ_8</b> — 0x4 <b>REQ_16</b> —
20 BURST_LEN_8	By default, when the LCDIF is in the bus master mode, it will issue AXI bursts of length 16 (except when in packed 24 bpp mode, it will issue bursts of length 15). When this bit is set to 1, the block will issue bursts of length 8 (except when in packed 24 bpp mode, it will issue bursts of length 9). Note that this bitfield is only applicable when LCDIF_MASTER is set to 1.
19 RSRVD4	This field is reserved. Reserved bits. Write as 0.
18–16 ODD_LINE_PATTERN	This field determines the order of the RGB components of each pixel in ODD lines (line numbers 1,3,5,...).  0x0 <b>RGB</b> — 0x1 <b>RBG</b> — 0x2 <b>GBR</b> — 0x3 <b>GRB</b> — 0x4 <b>BRG</b> — 0x5 <b>BGR</b> —
15 RSRVD3	This field is reserved. Reserved bits. Write as 0.
14–12 EVEN_LINE_PATTERN	This field determines the order of the RGB components of each pixel in EVEN lines (line numbers 2,4,6,...).  0x0 <b>RGB</b> — 0x1 <b>RBG</b> — 0x2 <b>GBR</b> — 0x3 <b>GRB</b> — 0x4 <b>BRG</b> — 0x5 <b>BGR</b> —

Table continues on the next page...

**LCDIF\_CTRL2n field descriptions (continued)**

Field	Description
RSRVD0	This field is reserved. Reserved bits. Write as 0.

**34.7.4 LCDIF Horizontal and Vertical Valid Data Count Register (LCDIF\_TRANSFER\_COUNT)**

This register tells the LCDIF how much data will be sent for this frame, or transaction. The total number of words is a product of the V\_COUNT and H\_COUNT fields. The word size is specified by the WORD\_LENGTH field.

This register gives the dimensions of the input frame. For normal operation, but V\_COUNT and H\_COUNT should be non-zero.

Address: 402B\_8000h base + 30h offset = 402B\_8030h

**LCDIF\_TRANSFER\_COUNT field descriptions**

Field	Description
31-16 V_COUNT	Number of horizontal lines per frame which contain valid data. In DOTCLK mode, V_COUNT should be the same as the number of active horizontal lines in a progressive frame.
H_COUNT	Total valid data (pixels) in each horizontal line. The data size is given by the WORD_LENGTH. In 24-bit packed format (WORD_LENGTH=0x3, BYTE_PACKING_FORMAT=0xF), the H_COUNT must be a multiple of 4 pixels. In 16-bit packed format (WORD_LENGTH=0x0, BYTE_PACKING_FORMAT=0xF), the H_COUNT must be a multiple of 2 pixels.

**34.7.5 LCD Interface Current Buffer Address Register (LCDIF\_CUR\_BUF)**

This register indicates the address of the current frame being transmitted by LCDIF.

When the LCDIF is behaving as a master, this address points to the address of the current frame of data being sent out via the LCDIF. When the current frame is done, the LCDIF block will assert the cur\_frame\_done interrupt for software to take action. The block will also copy the LCDIF\_NEXT\_BUF\_ADDR into this bitfield so that the software can program the next frame address into the LCDIF\_NEXT\_BUF\_ADDR bitfield. This address must always be double-word aligned.

Address: 402B\_8000h base + 40h offset = 402B\_8040h

### LCDIF\_CUR\_BUF field descriptions

Field	Description
ADDR	Address of the current frame being transmitted by LCDIF.

## 34.7.6 LCD Interface Next Buffer Address Register (LCDIF\_NEXT\_BUF)

This register indicates the address of next frame that will be transmitted by LCDIF.

When the LCDIF is behaving as a master, this address points to the address of the next frame of data that will be sent out via the LCDIF. It is up to the software to make sure that this register is programmed before the end of the current frame, otherwise it might result in old data going out the LCDIF. This address must always be double-word aligned.

Address: 402B\_8000h base + 50h offset = 402B\_8050h

### LCDIF\_NEXT\_BUF field descriptions

Field	Description
ADDR	Address of the next frame that will be transmitted by LCDIF.

## 34.7.7 LCDIF VSYNC Mode and Dotclk Mode Control Register0 (LCDIF\_VDCTRL0n)

This register is used to control the VSYNC and DOTCLK modes of the LCDIF so as to work with different types of LCDs like moving picture displays and delta pixel displays.

This register gives general programmability to the VSYNC signal including polarity, direction, pulse width, etc.

## LCDIF Memory Map/Register Definition

Address: 402B\_8000h base + 70h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
R	Reserved			ENABLE_PRESENT	VSYNC_POL	HSYNC_POL	DOTCLK_POL	ENABLE_POL	Reserved			VSYNC_PERIOD_UNIT	VSYNC_PULSE_WIDTH_UNIT	HALF_LINE	HALF_LINE_MODE	VSYNC_PULSE_WIDTH	
W																	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
R	VSYNC_PULSE_WIDTH																
W																	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

### LCDIF\_VDCTRL0n field descriptions

Field	Description
31–29 RSRVD2	This field is reserved. Reserved bits. Write as 0.
28 ENABLE_PRESENT	Setting this bit to 1 will make the hardware generate the ENABLE signal in the DOTCLK mode, thereby making it the true RGB interface along with the remaining three signals VSYNC, HSYNC and DOTCLK.
27 VSYNC_POL	Default 0 active low during VSYNC_PULSE_WIDTH time and will be high during the rest of the VSYNC period. Set it to 1 to invert the polarity.
26 HSYNC_POL	Default 0 active low during HSYNC_PULSE_WIDTH time and will be high during the rest of the HSYNC period. Set it to 1 to invert the polarity.
25 DOTCLK_POL	Default is data launched at negative edge of DOTCLK and captured at positive edge. Set it to 1 to invert the polarity. Set it to 0 in DVI mode.
24 ENABLE_POL	Default 0 active low during valid data transfer on each horizontal line.
23–22 RSRVD1	This field is reserved. Reserved bits. Write as 0.
21 VSYNC_PERIOD_UNIT	Default 0 for counting VSYNC_PERIOD in terms of DISPLAY CLOCK (pix_clk) cycles. Set it to 1 to count in terms of complete horizontal lines. DISPLAY CLOCK (pix_clk) cycles should be used in the VSYNC mode, while horizontal line should be used in the DOTCLK mode.
20 VSYNC_PULSE_WIDTH_UNIT	Default 0 for counting VSYNC_PULSE_WIDTH in terms of DISPLAY CLOCK (pix_clk) cycles. Set it to 1 to count in terms of complete horizontal lines.
19 HALF_LINE	Setting this bit to 1 will make the total VSYNC period equal to the VSYNC_PERIOD field plus half the HORIZONTAL_PERIOD field (i.e. VSYNC_PERIOD field plus half horizontal line), otherwise it is just VSYNC_PERIOD. Should be only used in the DOTCLK mode, not in the VSYNC interface mode.
18 HALF_LINE_MODE	When this bit is 0, the first field (VSYNC period) will end in half a horizontal line and the second field will begin with half a horizontal line. When this bit is 1, all fields will end with half a horizontal line, and none will begin with half a horizontal line.

Table continues on the next page...

## LCDIF\_VDCTRL0n field descriptions (continued)

Field	Description
VSYNC_PULSE_WIDTH	Number of units for which VSYNC signal is active. For the DOTCLK mode, the unit is determined by the VSYNC_PULSE_WIDTH_UNIT. If the VSYNC_PULSE_WIDTH_UNIT is 0 for DOTCLK mode, VSYNC_PULSE_WIDTH must be less than HSYNC_PERIOD. For the VSYNC interface mode, it should be in terms of number of DISPLAY CLOCK (pix_clk) cycles only.

### 34.7.8 LCDIF VSYNC Mode and Dotclk Mode Control Register1 (LCDIF\_VDCTRL1)

This register is used to control the VSYNC signal in the VSYNC and DOTCLK modes of the block.

This register determines the period and duty cycle of the VSYNC signal when it is generated in the block.

Address: 402B\_8000h base + 80h offset = 402B\_8080h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																																
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

## LCDIF\_VDCTRL1 field descriptions

Field	Description
VSYNC_PERIOD	Total number of units between two positive or two negative edges of the VSYNC signal. If HALF_LINE is set, it is implicitly calculated to be VSYNC_PERIOD plus half HSYNC_PERIOD.

### 34.7.9 LCDIF VSYNC Mode and Dotclk Mode Control Register2 (LCDIF\_VDCTRL2)

This register is used to control the HSYNC signal in the DOTCLK mode of the block.

This register determines the period and duty cycle of the HSYNC signal when it is generated in the block.

Address: 402B\_8000h base + 90h offset = 402B\_8090h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																																
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### LCDIF\_VDCTRL2 field descriptions

Field	Description
31–18 HSYNC_PULSE_WIDTH	Number of DISPLAY CLOCK (pix_clk) cycles for which HSYNC signal is active.
HSYNC_PERIOD	Total number of DISPLAY CLOCK (pix_clk) cycles between two positive or two negative edges of the HSYNC signal.

### 34.7.10 LCDIF VSYNC Mode and Dotclk Mode Control Register3 (LCDIF\_VDCTRL3)

This register is used to determine the vertical and horizontal wait counts.

This register determines the back porches of HSYNC and VSYNC signals when they are generated by the block.

Address: 402B\_8000h base + A0h offset = 402B\_80A0h

### LCDIF\_VDCTRL3 field descriptions

Field	Description
31–30 RSRVD0	This field is reserved. Reserved bits, write as 0.
29 MUX_SYNC_SIGNALS	When this bit is set, the LCDIF block will internally mux HSYNC with LCD_D14, DOTCLK with LCD_D13 and ENABLE with LCD_D12, otherwise these signals will go out on separate pins. This feature can be used to maintain backward compatible with 37xx.
28 VSYNC_ONLY	This bit must be set to 1 in the VSYNC mode of operation, and 0 in the DOTCLK mode of operation.

Table continues on the next page...

## LCDIF\_VDCTRL3 field descriptions (continued)

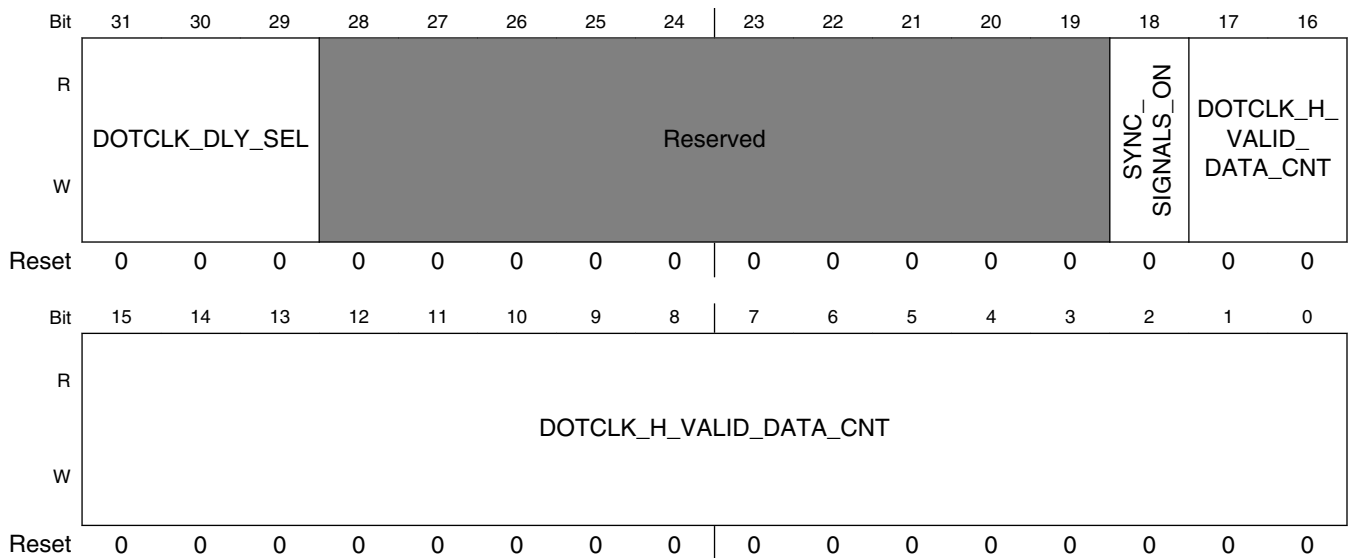

Field	Description
27–16 HORIZONTAL_WAIT_CNT	In the DOTCLK mode, wait for this number of clocks from falling edge (or rising if HSYNC_POL is 1) of HSYNC signal to account for horizontal back porch plus the number of DOTCLKs before the moving picture information begins.
VERTICAL_WAIT_CNT	In the VSYNC interface mode, wait for this number of DISPLAY CLOCK (pix_clk) cycles from the falling VSYNC edge (or rising if VSYNC_POL is 1) before starting LCD transactions and is applicable only if WAIT_FOR_VSYNC_EDGE is set. Minimum is CMD_SETUP+5. In the DOTCLK mode, it accounts for the vertical back porch lines plus the number of horizontal lines before the moving picture begins. The unit for this parameter is inherently the same as the VSYNC_PERIOD_UNIT.

### 34.7.11 LCDIF VSYNC Mode and Dotclk Mode Control Register4 (LCDIF\_VDCTRL4)

This register is used to control the DOTCLK mode of the block.

This register determines the active data in each horizontal line in the DOTCLK mode. Note that the total number of active horizontal lines in the DOTCLK mode is the same as the V\_COUNT bitfield in the LCDIF\_TRANSFER\_COUNT register.

Address: 402B\_8000h base + B0h offset = 402B\_80B0h

## LCDIF\_VDCTRL4 field descriptions

Field	Description
31–29 DOTCLK_DLY_SEL	This bitfield selects the amount of time by which the DOTCLK signal should be delayed before coming out of the LCD_DOTCK pin. 0 = 2ns; 1=4ns;2=6ns;3=8ns. Remaining values are reserved.
28–19 RSRVDO	This field is reserved. Reserved bits, write as 0.

Table continues on the next page...

**LCDIF\_VDCTRL4 field descriptions (continued)**

Field	Description
18 SYNC_ SIGNALS_ON	Set this field to 1 if the LCD controller requires that the VSYNC or VSYNC/HSYNC/DOTCLK control signals should be active at least one frame before the data transfers actually start and remain active at least one frame after the data transfers end. The hardware does not count the number of frames automatically. Rather, the VSYNC edge interrupt can be monitored by software to count the number of frames that have occurred after this bit is set and then the RUN bit can be set to start the data transactions. This bit must always be set in the DOTCLK mode of operation, and it must be set in the VSYNC mode of operation when VSYNC signal is an output.
DOTCLK_H_ VALID_DATA_ CNT	Total number of DISPLAY CLOCK (pix_clk) cycles on each horizontal line that carry valid data in DOTCLK mode.

**34.7.12 Bus Master Error Status Register (LCDIF\_BM\_ERROR\_STAT)**

This register reflects the virtual address at which the AXI master received an error response from the slave.

When the BM\_ERROR\_IRQ is asserted, the address of the bus error is updated in the register.

Address: 402B\_8000h base + 190h offset = 402B\_8190h

**LCDIF\_BM\_ERROR\_STAT field descriptions**

Field	Description
ADDR	Virtual address at which bus master error occurred.

**34.7.13 CRC Status Register (LCDIF\_CRC\_STAT)**

This register reflects the CRC value of each frame sent out by LCDIF. The CRC is done on the final output bus, so the value will be dependent on the LCD\_DATABUS\_WIDTH bitfield even if the input data is the same.

This register will be updated when the CUR\_FRAME\_DONE\_IRQ is asserted.

Address: 402B\_8000h base + 1A0h offset = 402B\_81A0h

## LCDIF\_CRC\_STAT field descriptions

Field	Description
CRC_VALUE	Calculated CRC value.

### 34.7.14 LCD Interface Status Register (LCDIF\_STAT)

The LCD interface status register can be used to check the current status of the LCDIF block.

The LCD interface status register that contains read only views of some parameters or current state of the block.

Address: 402B\_8000h base + 1B0h offset = 402B\_81B0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

## LCDIF Memory Map/Register Definition

### LCDIF\_STAT field descriptions

Field	Description
31 PRESENT	0: LCDIF not present on this product 1: LCDIF is present.
30 DMA_REQ	Reflects the current state of the DMA Request line for the LCDIF. The DMA Request line toggles for each new request.
29 LFIPO_FULL	Read only view of the signals that indicates LCD LFIPO is full.
28 LFIPO_EMPTY	Read only view of the signals that indicates LCD LFIPO is empty.
27 TXFIFO_FULL	Read only view of the signals that indicates LCD TXFIFO is full.
26 TXFIFO_EMPTY	Read only view of the signals that indicates LCD TXFIFO is empty.
25 -	This field is reserved. Reserved
24–9 RSRVD0	This field is reserved. Reserved bits. Write as 0.
LFIPO_COUNT	Read only view of the current count in Latency buffer (LFIPO).

### 34.7.15 LCDIF Pigeon Mode Control0 Register (LCDIF\_PIGEONCTRL0n)

This register contains global counter settings for Pigeon Mode also houses general purpose timing adjustment registers

Address: 402B\_8000h base + 380h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## LCDIF\_LUT\_CTRL field descriptions

Field	Description
31–1 Reserved	This read-only field is reserved and always has the value 0.
0 LUT_BYPASS	Setting this bit will bypass the LUT memory resource completely. No pixel transformations will occur at last stage before output to external display.

### 34.7.22 Lookup Table Control Register. (LCDIF\_LUT0\_ADDR)

Address: 402B\_8000h base + B10h offset = 402B\_8B10h

#### LCDIF\_LUT0\_ADDR field descriptions

Field	Description
31–8 Reserved	This read-only field is reserved and always has the value 0.
ADDR	LUT indexed address pointer. This address into the LUT memory is always four byte aligned for PIO access. The least two significant bits are not used to drive the LUT memory array. For PIO LUT access, when the LUT data register is written, the contents of the LUT at the address specified by this address field will be loaded with a 32-bit DWORD. This address pointer will be incremented after the LUT data is written. This will provide recursive writes to the LUT data register to initialize the entire LUT array with recursive writes to the LUT data register.

### 34.7.23 Lookup Table Data Register. (LCDIF\_LUT0\_DATA)

Address: 402B\_8000h base + B20h offset = 402B\_8B20h

#### LCDIF\_LUT0\_DATA field descriptions

Field	Description
DATA	Writing this field will load 4 bytes, aligned to four byte boundaries, of data indexed by the ADDR field of the REG_LUT_CTRL register.

### 34.7.24 Lookup Table Control Register. (LCDIF\_LUT1\_ADDR)

Address: 402B\_8000h base + B30h offset = 402B\_8B30h

#### LCDIF\_LUT1\_ADDR field descriptions

Field	Description
31–8 Reserved	This read-only field is reserved and always has the value 0.
ADDR	LUT indexed address pointer. This address into the LUT memory is always four byte aligned for PIO access. The least two significant bits are not used to drive the LUT memory array. For PIO LUT access, when the LUT data register is written, the contents of the LUT at the address specified by this address field will be loaded with a 32-bit DWORD. This address pointer will be incremented after the LUT data is written. This will provide recursive writes to the LUT data register to initialize the entire LUT array with recursive writes to the LUT data register.

### 34.7.25 Lookup Table Data Register. (LCDIF\_LUT1\_DATA)

Address: 402B\_8000h base + B40h offset = 402B\_8B40h

#### LCDIF\_LUT1\_DATA field descriptions

Field	Description
DATA	Writing this field will load 4 bytes, aligned to four byte boundaries, of data indexed by the ADDR field of the REG_LUT_CTRL register.

### 35.2 Overview

This document describes the micro-architecture for the Pixel Processing Pipeline used to process graphics buffers or composite video and graphics data before sending to an LCD display or TV encoder.

It is used to minimize the memory footprint required for the display pipeline and provide an area and performance optimized to both SDRAM-less and SRAM-based systems.

The PXP integrates of several independent processing stages into a cohesive strategy to create flexible pixel pipeline.

The PXP combines the following into a single processing engine:

- Scaling
- Color Space Conversion (CSC)
- Rotation

By integrating multiple blocks, intermediate buffer operations to external memory are removed, reducing external memory bandwidth, power, and software control complexity. The PXP block diagram is shown below.

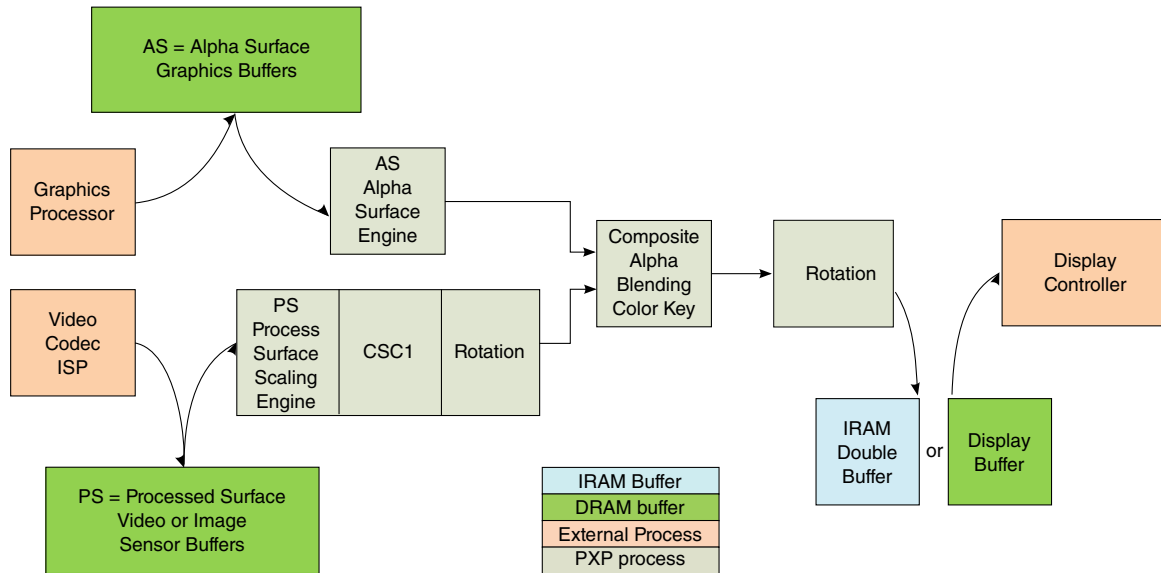

Figure 35-1. PXP Architecture

### 35.3 Clocks

The following table describes the clock sources for PXP. Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information.

Table 35-2. PXP Clocks

Clock name	Clock Root	Description
clk	ipg_clk_root	PXP clock

### 35.4 Top-level architecture

The PXP consist of several pipelined blocks that perform the video source frame scaling, color space conversion, alpha-blending/color key algorithm, secondary CSC, pixel correction.

The entire pipeline operate within the requirements of the PXP architecture, and perform operations on either 8x8 or 16x16 pixel blocks in the representative source buffers. The entire pipeline operate within the context of two iteration counters that iterate through the appropriate grid of input blocks to produce the rotated output grid blocks in scan-line order.

shows the high-level architecture of the scaling, color space conversion, blending, pixel correction, rotation engines. The Alpha Surface Engine fetches one RGB graphics plane alpha surface (AS). The scaling engine fetches a single processed surface (PS), which can be blended with the AS surface. Although the PXP processes NxN pixel macro blocks, each of the AS or PS surfaces can have any pixel alignment within the output buffer. There are no restrictions and any pixel coordinates within the output buffer are valid. The upper left origin of the output buffer is defined as pixel 0,0. The upper left and lower right coordinates for each of the AS and PS are inclusive within the output buffer.

**Figure 35-2** represents a sample output buffer configuration with both an AS and PS included. The alignment of each AS and PS within the output buffer can be at any arbitrary pixel locations. For example, the PS has an upper left coordinate (ULC) of 2,2 and a lower right coordinate (LRC) at pixel 13,13. The maximum value for the ULC and LRC for each of the AS and PS is bounded by the LRC of the output buffer, 15,15 for this example.

**Figure 35-2. Sample output buffer configuration**

The AS engine supports RGB pixel formats, and the PS engine supports RGB, YUV, and YCbCr pixel formats. The CSC1 can be used to convert to RGB pixel formats so that the PS surface can be blended with the AS surfaces in the compositing engine in the RGB color space. There is a single rotation engine in the PXP with a programmable location with two possible rotations, one after PS processing, other just before the transfer to display buffer. Rotation can occur after image composition or at the output of the PS engine. In the first scenario, all the data produced by the AS and PS engines is rotated. When the rotation module is programmed to rotate only PS images, the AS is not rotated, and AS pixels are combined with rotated PS surfaces.

### 35.4.1 Processing Details

The PXP architecture has been driven primarily by the requirement that the output buffer must be processed and rotated without intermediate frame buffer stored in external memory.

This reduces the use of external memory bandwidth requirements thus reducing overall system power consumed.

Since the output of the rotation block must be  $N \times N$  pixel blocks in scan order, the entire pipeline will operate on  $N \times N$  pixel blocks. In essence, the pipeline will be able to operate on blocks in a random access fashion, but the entire pipeline will operate within the context of two iteration counters that will iterate through the horizontal and vertical input blocks to generate the required output block.

### Processing Pipeline

The control block will coordinate the processing of the pixel blocks within the source and destination image buffers. It begins by issuing a command to each stage of the pipeline requesting that operations be done for the block at offset  $x, y$ . When the block accepts the command, it asserts its acknowledge signal for a single cycle to indicate the acceptance and allow the control unit to move to the next block.

When the PS and AS fetch engines have received a command, they will fetch the required data and place it into their fetch buffers. If compositing the RGB AS surface with the PS surface, then the output of the PS engine needs to be converted to the RGB color space using CSC1, since all compositing occurs in the RGB color space. For YUV output pixel formats, the CSC1 unit can be enabled to convert pixels into the RGB space for subsequent compositing with AS pixels. If the final output color space is YUV and there is no compositing required (AS not present, for example), then the CSC unit can be bypassed and the pixel data path will pass the YUV pixels to the rotation engine. For YUV output formats, scaling operations, and rotation operations are still valid, but blending RGB AS surfaces with YUV PS surfaces is NOT supported.

The alpha blender/color key module will process a pixel any time that both inputs present valid data.

A handshake will be created between each stage and a pipeline controller to handle the advance of the pipeline and generation of the iteration counters. The pipeline controller will also maintain the interlocks with the LCD interface for the case where the LCD display and pixel processing pipeline use the SRAM to maintain the double buffer block intermediate buffer.

### 35.4.2 Scaling Operation

The scaling engine operates on YUV (or YCbCr) 422 or 420 and any RGB formatted pixels. Each color plane is sourced from color planes indicated by different base address registers.

The scaling source data can be stored as 3 individual planes for each Y, U, and V data, stored as two planes as a single Y and interleaved UV plane, or stored as a single plane with YUV/RGB interleaved on a per byte basis.

The scaled output image is presented to the CSC module as YUV444 or RGB888 pixels with a single byte for each color channel. The scaler can reduce an input image by a maximum factor of 16. In this case, the output image will be 1/16 the dimension of the input image in each of the X and Y axis. There are no limits, essentially, on increasing the source image size. The theoretical maximum increase is 4096 since a 12 bit fractional step function is used when scaling an input image. Scaling in either axis, X or Y is independent, so a source image can appear stretched in either direction.

All source images pass through the scale engine. The PXP alpha blend module and AS pixel streams are in the RGB888 format, so PS pixel buffers must be converted to the RGB888 format for alpha blending. The scaling engine works with the CSC1 module to translate YUV/YCbCr pixel formats to RGB888 for output frame buffer compositing using the alpha blender. The CSC1 unit can be bypassed so compositing can occur in the alpha engine.

The scaling operation is divided into two scaling steps. The first step is a decimation scaler, and the second step is a bilinear filter. The decimation filter provide a maximum down scaling factor of 8, and the subsequent bilinear filter provides a maximum scaling factor of 2. Combined, the maximum scaling factor can be up to 16. The decimation and bilinear scaling engines are independently programmable. There is also an initial offset that is programmable to allow more source data to be considered in the bilinear scaling engine.

### **35.4.3 Decimation Image Scaling**

The first of two scaling engines is the decimation filter.

The intent of the decimation filter is to use as much source data as is possible to create the output image frame buffer. The decimation filter simply discards certain pixels from the source PS image depending on the reduction selected.

For RGB pixel formats, each color channel is treated equally since there is the same amount of pixel data within each color plane. For YUV422/420 formats, the chroma samples are already subsampled by 2. In these decimation scenarios, the chroma decimation factor is adjusted to account for the pre-decimation of the chroma samples. For example, since YUV422 is already sub-sampled by 2 horizontally, an X decimation factor of 2 does not apply to the YUV422 pixels in the X direction. All the chroma samples are passed on to the bilinear filter in this case. As another example, an X

decimation factor of 4 will decimate the chroma samples by 2, since this factor combined with the pre-decimation factor of 2 in the pixel source buffers totals an overall decimation factor of 4.

The following example will show which pixels (in green) in a source RGB buffer that are passed to the bilinear filter for an X decimation factor of 2 and a Y decimation factor of 4. All pixels coincident with dashed lines are discarded.

**Figure 35-3. RGB decimation X /2, Y /4**

Using the same decimation factor as the above scenario for RGB pixels, but using YUV420 source buffers, it can be shown that the decimation factor for the Y and UV components of data are decimated differently. This is due to the pre-decimation of the chroma samples in the source frame buffers. Figure 4: YUV420 decimation X /2, Y /4 indicates that the U/V samples in the X direction are not decimated, but the Y samples in the X direction are decimated by the factor of 2.

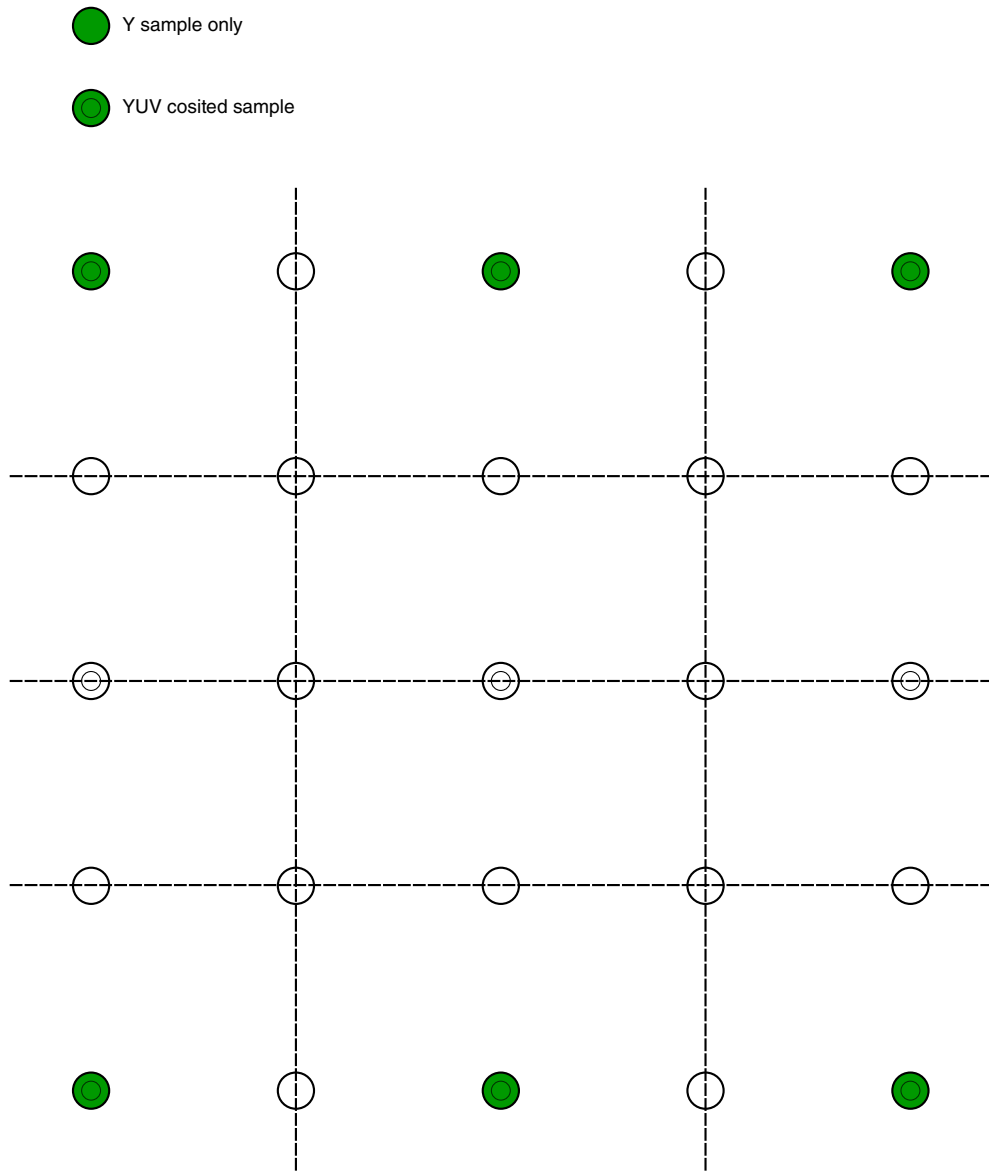

Figure 35-4. YUV420 decimation X /2, Y /4

### 35.4.4 Bilinear Image Scaling Filter

The PXP implements a bilinear scaling filter to resize an input image to a different resolution for display output.

The bilinear filter is a weighted average of the four nearest pixels that can be sourced to approximate the pixel in the output frame buffer.

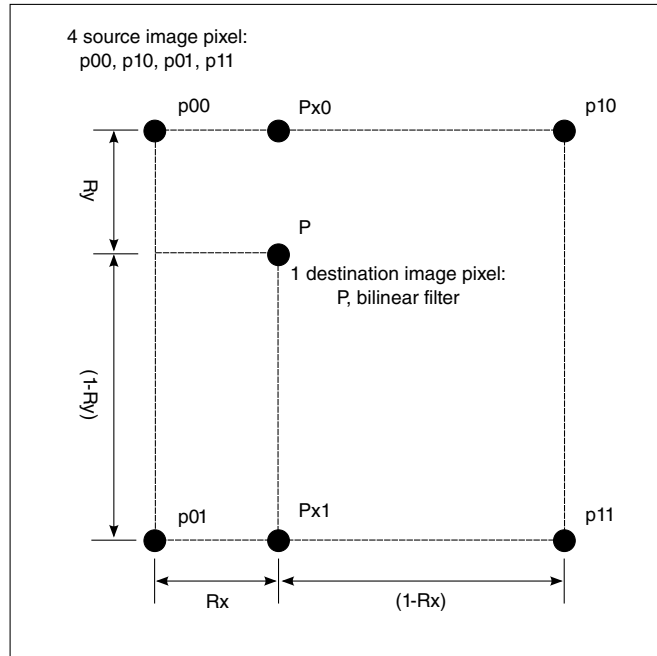

When scaling YUV data, the UV values are offset by 0x80 (top bit inverted) to shift the signed UV bits into an unsigned equivalent with a range of 0 to 255. YCbCr data does not have to be shifted since it is defined as an unsigned byte. The REG\_CSC1\_COEF0[YCBCR\_MODE] bit controls whether this operation is applied to the input UV bytes.

After scaling, the offset is removed so that the range for UV data is signed from -128 to 127.

The reason for this adjustment is based on the implementation of an unsigned scaling engine, and therefore, is to ensure that the scaled values are handled properly. Consider the following table:

Format	pixel0	pixel1	average	Result
decimal	-2	+2	0	Correct
CbCr	0x7E	0x82	0x80	Correct (0x80 is 0 in CbCr)
UV	0xFE	0x02	0x80	Incorrect (0x80 is -128 in UV)
decimal	-32	+16	-8	Correct
CbCr	0x60	0x90	0x78	Correct (0x78 is -8 in CbCr)
UV	0xE0	0x10	0x78	Incorrect (0x78 is +120 in UV)

To compute the output pixel value at position as indicated by P, consider the diagram below.

**Figure 35-5. Output Pixel Value**

A step function is used to indicate the position of the pixel "P" in the output frame. This position may not coincide with a single pixel position in the input frame buffer. In this case, the four closest pixels in the input frame are used to approximate the value of the pixel in the output frame.

The PXP scaler first computes a linear filter in the X axis to create the two intermediate pixel values Px0 and Px1. The step function's X fractional component is used to provide the weighting factor for blending p00 with p10 to provide Px0. Likewise, Px1 is also derived from a linear filter using p01 and p11.

The equations for Px0 and Px1 are as follows:

$$Px0 = p00*(1-Rx) + p10*Rx$$

$$Px1 = p01*(1-Rx) + p11*Rx$$

The PXP scaler uses the intermediate X pixels Px0 and Px1 and implements a bilinear filter on these two pixel values to produce the final pixel value at position P. The remainder of the step function for the Y axis is used to compute the weighted average pixel result. The equation for final filtered pixel is:

$$P = Px0*(1-Ry) + Px1* Ry$$

### 35.4.5 YUV 4:2:2 Image Scaling

The following figure illustrates the positioning of YUV samples for the 4:2:2 formats. There are twice as many Y luma samples then U and V chroma samples horizontally.

**Figure 35-6. YUV Sample Positioning, 4:2:2**

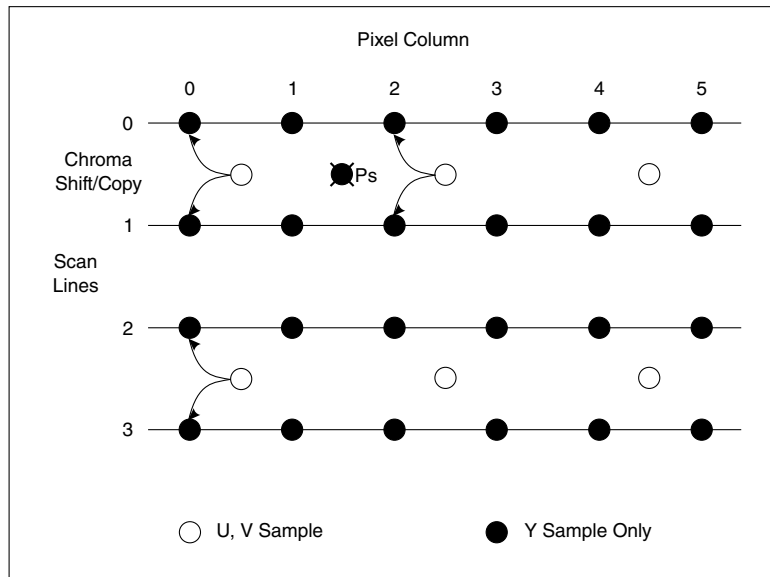

Consider the scaled output pixel  $P_s$  (pixel scaled) which has an accumulated step function of  $X=1.5$  and  $Y=0.5$ . The remainder for the step function is  $R_x = 0.5$  and  $R_y = 0.5$ . Or, the sub pixel position of output pixel  $P_s$  is half way between line 0 and 1 and half way between column 1 and 2.

The Y output component of  $P_s$  is simply the bilinear function of the four nearest Y samples from the input image. Specifically, the Y values at [1,0], [2,0], [1,1], and [2,1] are used to compute the Y for  $P_s$ .

For the U and V components of  $P_s$ , there are no samples present in the column position 1. The bilinear filter uses chroma components located at [0,0], [2,0], [0,1] and [2,1]. Since the chroma components are not sub sampled vertically, the remainder used to combine pixels vertically is  $R_y=0.5$  (the same as for Y). However, horizontally, the scaling engine shifts the remainder by a factor of 2. So an X axis step function value of  $X=1.5$  has a remainder  $R_x=0.75$ . Source chroma values are not replicated, they are completely interpolated using the four nearest chroma samples to approximate U and V at  $P_s$ .

## 35.4.6 YUV 4:2:0 Image Scaling

The following figure illustrates the positioning of YUV samples for the 4:2:0 formats. Chroma is sub sampled both horizontally and vertically. In this format, the chroma frame buffers contain  $\frac{1}{4}$  the data that the luma frame buffers store.

**Figure 35-7. YUV Sample Positioning, 4:2:0**

The Y output component for all scaled pixels in 4:2:0 formats are the same as for the 4:2:2 pixel formats.

The U and V output components have two considerations when computing the output pixel Ps.

1. All chroma samples from the input source image are shifted left and up by  $\frac{1}{2}$  a sample position of the input pixel matrix.
2. Odd scan lines are replicated using the previous even chroma scan line values. So, output image chroma values that map between even to odd scan lines are replicated in the vertical axis. In contrast, output image chroma values between odd to even scan lines are interpolated vertically.

The chroma values are interpolated horizontally as in the 4:2:2 pixel format.

As an example, consider the interpolated pixel Ps in the 4:2:0 diagram above. For the Y component, the interpolated output luma is a function of the Y values in the source frame buffer at position [1,0], [2,0], [1,1], [2,1].

For the U and V interpolated samples, the chroma values on scan line position 0.5 are shifted so that they coincide with the even luma sample points. They are also replicated so that a single chroma scan line is used twice. The chroma scan line at 0.5 is replicated to represent the 4:2:2 sample points for scan line 0 and 1. The chroma scan line at 2.5 is replicated to represent the 4:2:2 sample points for scan line 2 and 3. This pattern of chroma replication occurs for the entire source frame buffer during the scaling operation.

**Figure 35-8. Scaled Chroma Computation Examples**

The preceding diagram has two examples for the computation of the scaled chroma output pixel. For chroma at output position PsA (vertical position 0.5), interpolation occurs in the X axis using chroma values at column 0 and column 2. However, since line 0 and line 1 have equal chroma values due to chroma line replication, scaling in the Y axis results in replication of chroma values.

For chroma at output position PsB (vertical position 1.5), interpolation occurs in both the X and Y axis. The Y axis is an interpolation since the chroma values copied to scan line 1 and 2 and not the same.

In summary, any output image pixels that map to an odd scan line above and an even scan line below are interpolated vertically. Output image pixels that map to an even scan line above and an odd scan line below are replicated vertically.

### 35.4.7 RGB/YUV444 Image Scaling

For all RGB formats, the RGB pixels are converted up to RGB888 with 8 bits per each color component.

Then each color component is passed to the scaling engine and each component is treated in the same manner. The RGB scaling operation is the same as for the Y scaling operation described in the preceding sections. Also, YUV444 contains a byte for each color plane at each pixel location, so all three color components are scaled in the same manner.

### 35.4.8 Color Space Conversion (CSC)

The CSC unit converts pixels between color spaces. The CSC1 unit is right after the scaling unit and is dedicated to converting from YUV to RGB. All coefficients are programmed as two's complement numbers and CSC unit can be bypassed if conversion is not desired in the pixel data path.

### 35.4.9 CSC1 Operation

The CSC1 module receives scaled YUV/YCbCr444 pixels from the scale engine and converts the pixels to the RGB888 color space only if CSC1 is enabled.

The CSC1 module will convert only to the RGB color space and it can be bypassed to allow YUV pixels through the data path. These pixels are loaded into the pixel FIFO for processing by subsequent modules in the pixel data path.

The following equations are used to perform YUV/YCbCr → RGB conversion. The constants will be stored in the PXP control registers as two's complement values to allow flexibility in the implementation and to allow for differences in the video encode and decode operations. In addition, this provides a software mechanism to manipulate brightness or contrast.

$$R = C0(Y+Yoffset) + C1(V+UVoffset)$$

$$G = C0(Y+Yoffset) + C3(U+UVoffset) + C2(V+UVoffset)$$

$$B = C0(Y+Yoffset) + C4(U+UVoffset)$$

Note: In the equations above, U and V are synonymous with Cb and Cr in regards to the color space format of the source frame buffer.

Saturation of each color channel is checked and corrected for excursions outside the nominal YUV/YCbCr color spaces. Overflow for the three channels are saturated at 0x255 and underflow is saturated at 0x00.

The table below indicates the expected coefficients for YUV and YCbCr modes of operation:

Coefficient	YUV	YCbCr
Yoffset	0x000	0x1F0 (-16)
UVoffset	0x000	0x180 (-128)
C0	0x100 (1.00)	0x12A (1.164)
C1	0x123 (1.140)	0x198 (1.596)
C2	0x76B (-0.581)	0x730 (-0.813)
C3	0x79B (-0.394)	0x79C (-0.392)
C4	0x208 (2.032)	0x204 (2.017)

### 35.4.10 YUV versus YCbCr Support

By default, the PXP color space coefficients are set to support the conversion of YUV data to RGB data.

If YCbCr input is present, software must change the coefficient registers appropriately (see the register definitions for values). Software must also set the YCBCR\_MODE bit in the COEFF0 register to ensure proper conversion of YUV versus YCBCR data.

### 35.4.11 Alpha Blending/Color Key

Regardless of pixel input format, the PS and AS pixels are normalized to 32-bits, organized as one alpha and three data bytes. Alpha blending occurs in the RGB space, if blending is required, PS pixels should be converted to RGB space. If no alpha blending is required, then YUV pixels can bypass the alpha blending ALU without color space conversion. All pixels are processed by the pixel ALU, but the ALU operations can be disabled to achieve pixel pass through for either PS or AS source pixels.

### 35.4.12 Alpha Blend

The alpha value for an individual pixel represents a mathematical weighting factor applied to the AS pixel. An alpha value of 0x00 corresponds to a transparent pixel and a value of 0xFF corresponds to an opaque pixel.

The effective alpha value for an AS pixel is determined by the AS\_CTRL[ALPHA] and AS\_CTRL[ALPHA\_CTRL] register fields. If AS\_CTRL[ALPHA\_CTRL] = ALPHA\_OVERRIDE, the alpha value for the pixel is taken from the AS\_CTRL[ALPHA]. This can be useful for applying a constant alpha to an entire image or for image formats that don't include an alpha value. If AS\_CTRL[ALPHA\_CTRL] =

ALPHA\_MULTIPLY, the pixel's alpha value will be multiplied by the pixel's ALPHA value in order to allow scaling of the pixel's alpha or to provide better control for pixel formats such as RGB1555, which only contains a single bit of alpha.

For each color channel, the equation used to blend two source pixels is defined below:

$Gá$  = PIO programmed global alpha (8-bit value).

$Eá$  = Embedded alpha associated with AS pixel.

$\acute{a}$  =  $Gá * Eá + 0x80$

The result for the red channel as an example:

$R[7:0] = (\acute{a} * PS.r) + ((1 - \acute{a}) * AS.r)$

When  $\acute{a}$  is 0xff, the PS pixel will not be blended with the AS pixel, but PS will be passed as the output pixel and will not be blended with AS. In this case, AS will be discarded. Likewise, if  $\acute{a}$  is 0x00 for a given pixel, PS will be loaded as the output pixel.

AS\_CTRL[ALPHA\_INVERT] provides the option to invert the final alpha value. This essentially inverts the effect the alpha value has on the AS and PS blending operation.

### 35.4.12.1 Porter-Duff Alpha Blend

Porter-Duff blend includes 12 blending modes to describe digital image composite. These processes include Clear, Source Only, Destination Only, Source Over, Source In, Source Out, Source Atop, Destination Over, Destination In, Destination Out, Destination Atop and XOR. Through these process it can achieve any 2D image composite.

To control the blending modes, please see below picture. All the registers showed below are included in HW\_PXP\_ALPHA\_A\_CTRL.

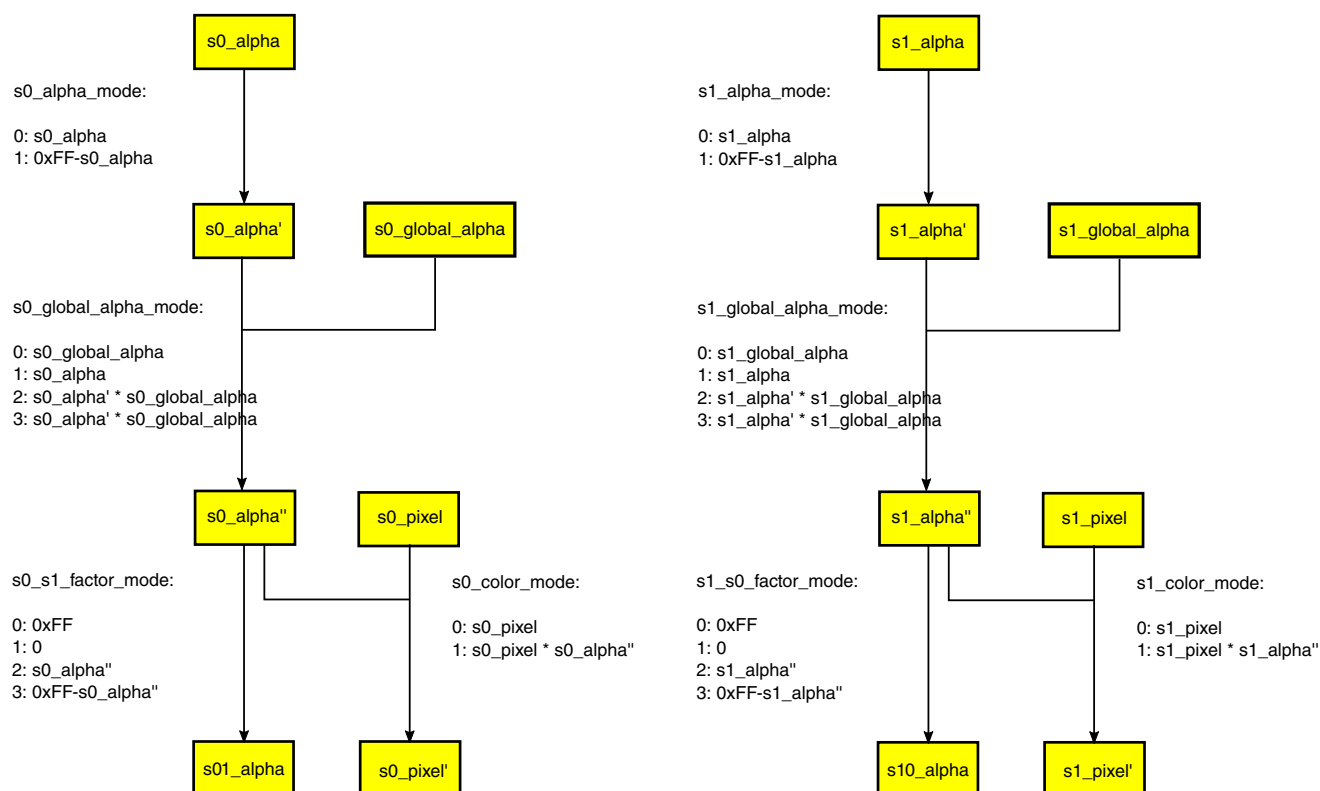

Figure 35-9. Porter-Duff Alpha Blend

### 35.4.13 Color Key

The color key function is provided to create transparent effects on the output pixel.

Color keying is applied on the input pixels after they are converted to 8-bits for each red, green, and blue color channels (color keys are not applied directly to 16-bit pixel formats but to their corresponding 24-bit representation). A color key range is programmable for both PS and AS pixels. If the PS 24-bit pixel is within the PS color key range, then AS is passed through the pixel pipeline. In this case, alpha blending does NOT occur.

Conversely, if PS is within the AS color key range, then PS is passed via the PXP data pipeline. If both PS and AS color key tests pass, then the back ground color register is passed onto following PXP processing components in the pipeline.

The condition for color keying to be satisfied is:

$$CK0.r.low \leq PS.r \leq CK0.r.high$$

$$CK0.g.low \leq PS.g \leq CK0.g.high$$

$$CK0.b.low \leq PS.b \leq CK0.b.high$$

For example, if the "red" 8-bit value for the PS pixel (or PS.r) is between the color key low and high values (CK0.r.l and CK0.r.h), the condition is true for the red color plane. When ALL three color planes meet this condition, then only the PS pixel is loaded into the output register.

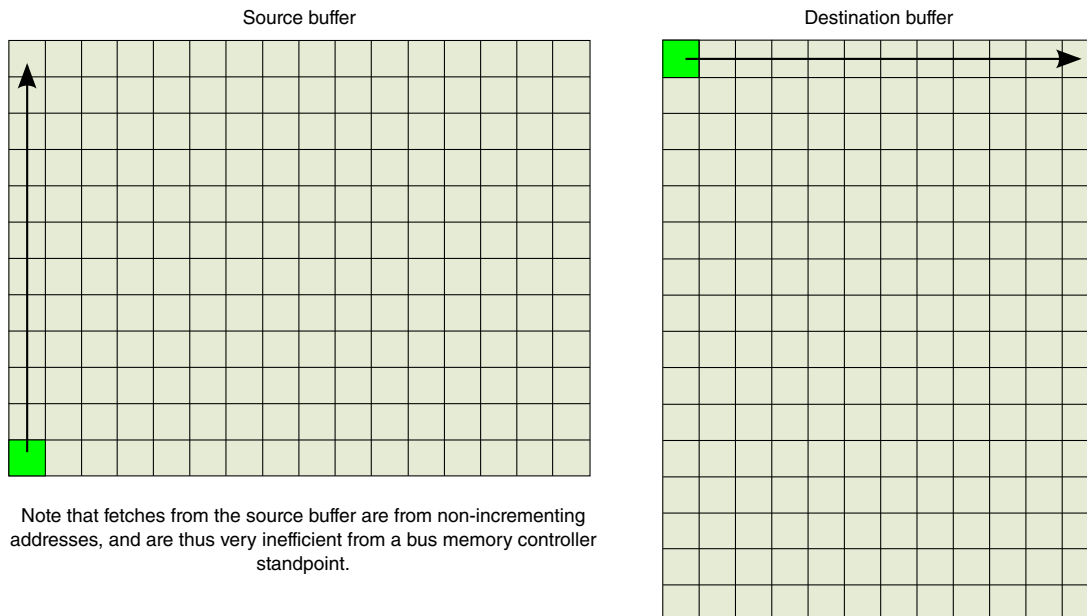

To disable color keying, program the low color key register value to 0xff and the high value to 0x00. This will guarantee that the color key range test will never be true.

### 35.4.14 Rotation

There is a single rotation resource integrated into the PXP. The location of this resource within the PXP data path is programmable. Rotation can occur after compositing the AS and PS buffers in the output stage.

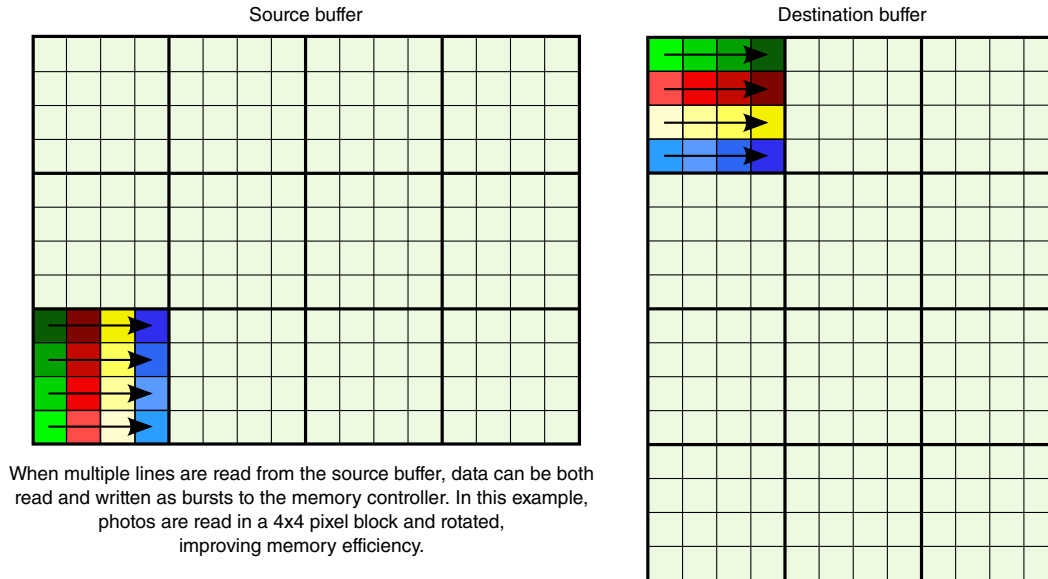

As an alternative configuration, the PS buffer can be rotated and later composited with the AS surface that is not rotated. There is a single configuration bit that provides the configuration of where rotation is implemented within the PXP.

To rotate graphics, the hardware must read pixels in one direction across a frame buffer and write them in a alternate orientation. For the 90 and 270 degree cases, this means that lines of pixels must either be read or written vertically in a frame buffer.

**Figure 35-10. Rotation Read and Write**

In order to rotate efficiently, multiple columns must be rotated to enable the engine to both fetch and store bursts of pixels, thus improving memory performance. The simplest method of doing this is to operate on square blocks of pixels. To rotate the image, each sub-block of pixels must be rotated by the required rotation angle.

**Figure 35-11. Rotated Sub-blocks**

To manage the rotation process, the source image can be broken into a grid of sub-blocks that have coordinates as shown in the diagram below. In addition to rotating the sub-block, each block must be translated to a new coordinate location. For each of the rotation angles (0, 90, 180, 270), it is possible to define a simple algorithm for computing the new translated grid address. The hardware must then simply compute the memory address from the base grid address for both load and store operations.

**Figure 35-12. Grid of Sub-Blocks with Coordinates**

In order to balance the requirements of reasonable burst sizes to the memory controller as well as keep the hardware storage requirements to a minimum, the blending/rotation engine will operate on either 8x8 or 16x16 pixel blocks. When using the Rotate engine with the input fetch engine, you need to program the input fetch engine to work in 8x8 block mode.

**NOTE**

An important artifact of the PXP is when rotating a source image and the output is NOT divisible by the block size selected. The output engine essentially truncates any output pixels after the desired number of pixels has been written. Since the output buffer is written as a horizontal row of blocks, the incorrect pixels could be truncated and the final output image can look shifted. In the case where the block size is programmed to 8x8, and the output size that is programmed is 12x12, then there is a remainder of 4 pixels that will be truncated in either the X and/or Y axis when the PXP operation is complete. The output will be shifted by 4 pixels in this example. To compensate for this, the source base address needs to be adjusted so the correct pixels get truncated and the image does not look shifted. In this example, with 90 degrees of rotation, the PS base address should be adjusted by 4 times the actual PS base address  $-(4 * \text{pitch})$ .

### 35.4.15 Output Buffer

The output buffer engine accepts data from the PXP pixel pipeline and issues requests to transfer the output pixels to external DRAM or the internal SRAM double buffer row of blocks.

### 35.4.16 Address calculator

Each of the blocks will manage its own fetch address using a common address calculator block that computes real addresses from a base address and relative block offset from the base.

Each block will then perform the multiple line fetches (or stores) required to perform the operation. This hides all the address buffer computations from the processing blocks and allows each block to simply track the coordinate of the block it is working on.

### 35.4.17 Block size selection

The PXP can be configured to process blocks that are either 8x8 pixels or 16x16 pixels with the REG\_CTRL[BLOCK\_SIZE] control bit.

When selecting a 16x16 pixel block size, the accesses to fetch AS and PS images and write the final frame buffer are more efficient since twice as much data is requested and processed per memory request.

When optimizing the system for memory bandwidth and image processing time, configure the PXP to process 16x16 pixel blocks.

### 35.4.18 Interlaced Video Support

The PXP has some minimal ability to generate interlaced video content from a progressive source. There two available options, based on the bandwidth requirements and how software is managing video frames.

The PXP can either interlace on the input side (by reading every other line of input data) or on the output side (by writing the individual lines of video into two separate fields). Generally, output interleaving should be used since it is the most flexible mode (it allows scaling and full overlay support) and it only requires a single pass of the PXP to generate two separate output fields.

Input interleaving can be beneficial in cases where the PXP is running at 60fps, since it requires fewer fetches to produce the output data. There is no direct hardware support for input interleaving, in that, there is no configuration bit that can be set to alter how the PXP processes a frame for input interleaving. Input interleaving is achieved by simply setting the source frame buffer pitch value to twice the value it would normally be set to for the equivalent progressive frame. The output parameters also need to be consistent with the desired processing effect. For example, the vertical resolution would be set to account for the reduced resolution to process the interlaced input buffers.

### 35.4.19 LCDIF Handshake

The PXP and LCDIF support a mode where the internal SRAM can be used for the frame buffer to minimize external memory bandwidth required.

This is accomplished by creating two buffers in SRAM, a double buffer row of blocks, where each correspond to 8/16-lines of the frame buffer. The buffers must be consecutive and allocated as a single block of data.

**Figure 35-13. Buffer in OCRAM**

The storage required can be calculated for an 8x8 block size as

- storage = 16 (lines) \* rotated\_row\_length \* pixel\_size

and for 16x16 block size as

- storage = 32 (lines) \* rotated\_row\_length \* pixel\_size

where pixel\_size = 4 for 32bpp or 2 for 16bpp modes. The following table lists the storage requirements for common image sizes using 8x8 block size:

Image Size	Storage (16bpp)	Storage (24bpp)	Storage (32bpp)
320x240 (QVGA) - 0/180 rotation	10KB	15KB	20KB
320x240 (QVGA) - 90/270 rotation	7.5KB	11.5KB	15KB
640x480 (VGA) - 0/180 rotation	20KB	30KB	40KB

*Table continues on the next page...*

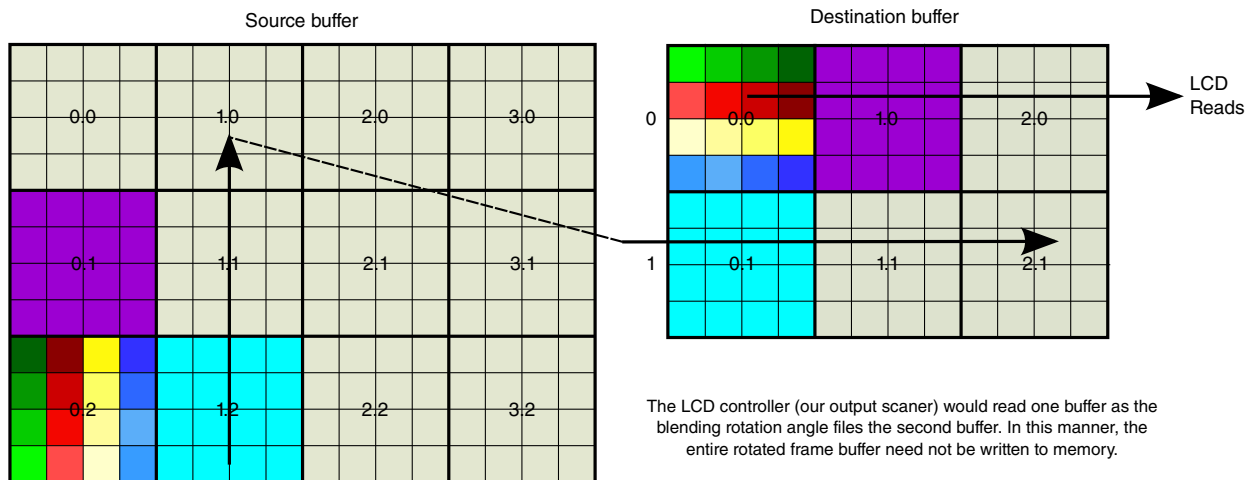

640x480 (VGA) - 90/270 rotation

15KB

22.5KB

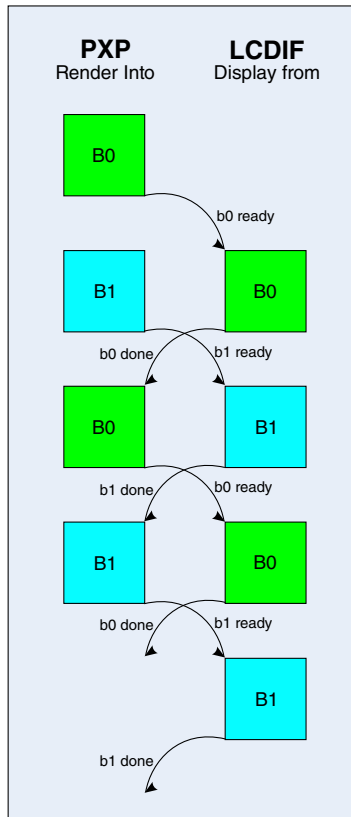

30KB

The following diagram shows how the minimal rotation buffer would be organized. As the engine and LCD progress down the image, they continually swap roles of filling and emptying each eight-line buffer.

**Figure 35-14. Minimal Rotation Buffer Organization**

When this mode is enabled, the PXP will process one row of pixel blocks and write the results to the first SRAM buffer (buffer 0). The PXP will then alternate between writing subsequent rows to buffer 0 and buffer 1. After the PXP generates the data for one buffer, the LCDIF will begin reading that buffer and send the contents to the display device. Once the LCDIF finishes reading a buffer, it will start displaying from the other buffer while the PXP continues filling the previously processed buffer.

**Figure 35-15. PXP and LCDIF Buffer Sharing**

To accomplish the buffer sharing, the PXP and LCDIF will maintain buffer status using a pair of handshake signals. When a buffer is filled by the PXP, it will assert the `pxp_lcdif_bx_ready` (where x is 0 or 1) signal to indicate to the LCDIF that the buffer has valid data. The LCDIF will then release the buffer by asserting the `lcdif_pxp_bx_done` signal.

The basic protocol is shown in the diagram below:

**Figure 35-16. Buffer Sharing Protocol**

The PXP will continue to assert the `bx_ready` signal until the corresponding `bx_done` signal is sampled high for one clock cycle. It will then deassert the `bn_ready` until the next time the buffer has been filled. After the PXP samples the `bx_done` signal asserted, it is free to begin filling the buffer with the next block size lines of display data. If a buffer has not been released when the PXP is ready to process data for that buffer, it will suspend rendering operations until the buffer has been released by the LCDIF.

### 35.4.20 LCDIF Abort

When the memory subsystem is not loaded, the PXP should be able to render the buffers faster than the LCDIF can drain the buffers.

It is possible under some scenarios (high LCDIF output rates with high memory latency) that the PXP may not be able to keep up with the LCDIF, even in the SRAM mode of operation. When this happens, the LCDIF will signal that it has completed one of the buffers before the other has been rendered by the PXP. This condition will be detected by the PXP's control logic as an "LCDIF Abort", which will cause the PXP to abort processing in the current row and proceed to the following row. It will acknowledge the abort to the LCDIF by raising the `buffer_ready` signal for the current buffer to enable the LCDIF to begin displaying the partially-filled buffer. While an abort will create artifacts in the video display, it does minimize the artifacts by limiting them to the remaining pixels blocks in the current row versus ruining the entire frame buffer.

Figure 35-17. LCDIF Abort

### 35.4.21 Theory of Operation

The PXP can be used to accelerate graphics operations by offloading graphics processing from the processor. The block can perform alpha blending and color key substitution on two RGB graphics buffers.

The PXP is organized as having a processed surface (PS) and an alpha surface (AS) that can be blended with the processed surface. There are no restrictions on the location of the AS or PS within the output surface (OS). As the PXP processes NxN blocks, operations

are performed on a pixel by pixel basis. The AS and PS pixels are alpha blended, color keyed, process by CSC resources as individual pixel components. This allows efficient block processing with supporting arbitrary alignment for both the AS and PS surfaces. The resulting pixel block is then written to the corresponding block in the output buffer.

### 35.4.22 Pixel Handling

All pixels are internally represented as 32-bit values regardless of input or output pixel formats. The pixels get converted in the AS and PS buffer engines to 24-bit pixel values. There is also an 8-bit alpha value at stages up to the alpha blender within the PXP for blending within the RGB color space. Compositing of AS and PS images can only occur in the RGB color space. If compositing is not required, then YUV pixels can be transferred and processed at all PXP pixel resource components.. The color orientation of pixels within the PXP can be controlled by the CSC1 resource.

For RGB, input pixels are converted into 32-bit pixel values using the following rules for both AS and PS:

1. 32-bit ARGB8888 pixels are read directly with no conversion.
2. 32-bit RGB888 pixels are assumed to have an alpha value of 0xFF (full opaque).
3. 6-bit RGB565 and RGB555 values are expanded into the corresponding 24-bit color space and assigned an alpha value of 0xFF (opaque). The expansion process replicates the upper pixel bits into the lower pixel bits (for instance a 16-bit RGB555 triplet of 0x1F/0x10/0x07 would be expanded to 0xFF/0x84/0x39).
4. 16-bit RGB1555 values are expanded into the corresponding 24-bit color space and assigned an alpha value of either 0x00 or 0xFF, based on the 1-bit alpha value in the pixel. The ALPHA\_MULTIPLY function is useful in this scenario to allow scaling of the opaque pixels to a semi-transparent value.

Alpha values can be passed through the entire PXP data path and output in ARGB888 and ARGB555 pixel modes. Also, output pixels can be assigned an alpha value using the REG\_OUT\_CTRL[ALPHA] register. 16-bit pixels values are formed from the most significant bits of the 24-bit pixel values.

When YUV/YCbCr output formats are selected, all pixels are internally represented as either RGB or YUV pixels values.

### 35.4.23 Output Buffer Composition

The output buffer will be rendered by composing each pixel block from the associated PS and AS buffers.

The AS pixel buffer can be blended or color-keyed with the associated data from the PS buffer (either the PS image pixels or REG\_PS\_BACKGROUND register based on PS programmed coordinates).

Figure 35-18. Output Buffer Composition

### 35.4.24 PS Image Processing

As the PXP processes image buffers, it iterates over the output buffer by fetching the corresponding input buffer blocks and processing the pixels embedded in these.

### 35.4.25 Letterboxing

At each pixel coordinate, the control logic determines if the PS pixel (argument also applies to AS pixels) will be used in rendering the output pixel.

This is determined by checking the output pixel's coordinates against the REG\_OUT\_PS\_ULC and REG\_OUT\_PS\_LRC (ULC and LRC in short) register contents. For pixels outside this region, the PS pixel will be loaded with the pixel value from REG\_PS\_BACKGROUND, which can be used to effectively control the letterboxing color. There are no block size or block boundary restrictions when setting the ULC or LRC for either the AS or PS. The only restriction is that the ULC and LRC are within the OUT LRC extents.

**Figure 35-19. OUT Buffer**

### 35.4.26 Clipping source images

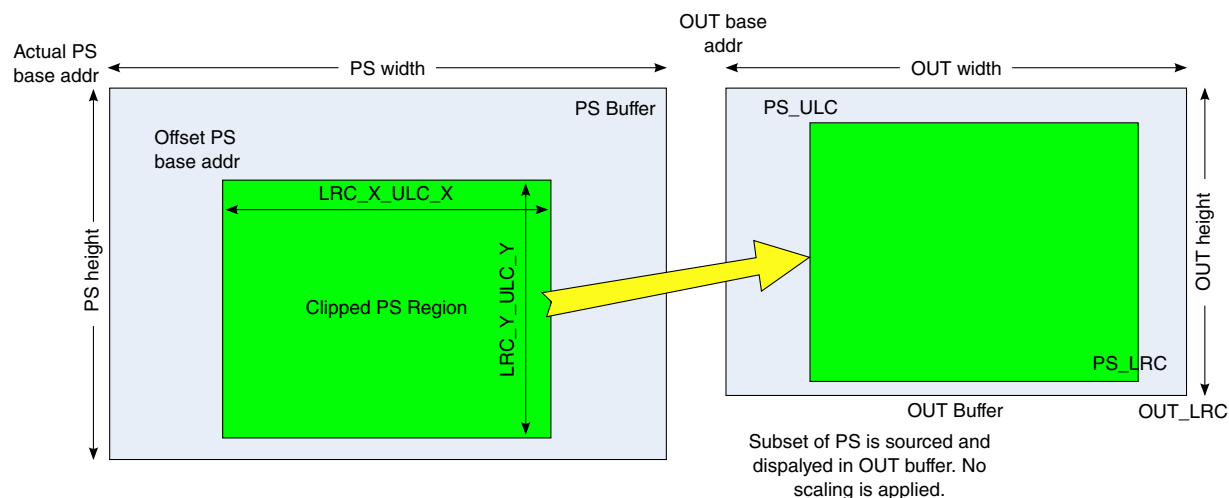

A subset of the PS buffer can be used in rendering the output buffer. The PXP\_PS\_BUF register can indicate an offset into the PS buffer that will be used for display within the OUTPUT buffer.

The pixel at the address defined in the PXP\_PS\_BUF register will be the pixel that is displayed at the pixel coordinate indicated by PXP\_OUT\_PS\_ULC within the output buffer. Essentially, the PXP\_PS\_BUF register can be used to establish an offset into the PS buffer thus clipping all PS buffer pixels that are at a lower address. The PXP\_PS\_PITCH will always indicate the number of bytes that are vertically adjacent in

the PS buffer. The settings in the PXP\_PS\_BUF, PXP\_OUT\_PS\_ULC, and PXP\_OUT\_PS\_LRC will determine the subset of the PS buffer, or clipped PS source buffer, that will be used in the output buffer.

It is important to note that when scaling the PS buffer, the coordinates of the PS buffer within the output buffer need to be consistent with the scaling factors and original PS buffer size.

**Figure 35-20. PS Buffer Scaling**

When sourcing a subset of the PS image, it should fall completely within the PS buffer to avoid displaying incorrect data. The following conditions should be met:

$$x\_base\_addr\_offset + x\_scale * (LRC\_X - ULC\_X) \leq PS\_pitch$$

$$y\_base\_addr\_offset + y\_scale * (LRC\_Y - ULC\_Y) \leq PS\_size$$

The PXP hardware does not check for these conditions and will render the image as programmed. The following case could indicate invalid programming parameters for the PXP:

**Figure 35-21. Example with Invalid Parameters**

### 35.4.27 Color Key Processing

Pixels may be made transparent to the corresponding AS by using the PS color key registers.

If a PS pixel matches the range specified by the REG\_PS\_COLORKEYLOW and REG\_PS\_COLORKEYHIGH registers, the pixel from the associated AS will be displayed. If no AS is present for the pixel, a black pixel will be generated since the default AS pixel is 0x00000000 (transparent black pixel).

The most common use for this is when a bitmap does not support an alpha-field or for applications such as "green screen" where an image is substituted for a solid background color .

**Figure 35-22. The PS image (player) and AS image (stadium)**

The green portion of the background image can be color keyed to display the contents of the AS buffer for locations that match the color range. For this example, the color range is:

PS Colorkey: 00<R<80 70<G<ff 00<B<80

The resulting image becomes:

**Figure 35-23. Resulting Image**

### 35.4.28 In Place Processing (PS buffer is destination buffer)

The PXP also has the ability to process an image and write the resulting buffer back to the original PS buffer. This is referred to as "in place" rendering.

This could be useful for basic blit operations into the PS buffer. IN\_PLACE operations are achieved by programming the OUT base address to the pixel location in the PS buffer that marks the upper left pixel of the update region. The actual region that is updated should be indicated by programming the ULC = (0,0) and the LRC = (X,Y). The region bounded by the coordinates will be updated, and the rest of the PS buffer will not be modified.

### 35.4.29 Alpha Surface (AS) Processing

The AS surface has a complete set of registers that determines how the AS effects the final OUT surface.

Most of the registers that exist for the PS surface also are defined for the AS surface where applicable. This is provided to replicate the SW interface for each PS and AS processes.

### 35.4.30 Alpha Handling

Alpha values in the AS are embedded in the source image pixels. For AS pixel formats that do not support an alpha value, the pixel is assigned an alpha value of 0xFF (opaque).

This can be modified by the AS control by setting either the ALPHA\_MULTIPLY or ALPHA\_OVERRIDE bit in the associated AS\_CTRL register. If ALPHA\_MULTIPLY is enabled, the 8-bit ALPHA value from the AS\_CTRL register is multiplied by the source alpha before blending with the PS image. If the ALPHA\_OVERRIDE bit is set, the 8-bit ALPHA value is simply substituted for the pixel.

### 35.4.31 Color Key Processing (AS\_CTRL)

The AS\_CTRL register also contains an ENABLE\_COLORKEY bit that can be used to enable or disable color key substitution for the AS.

When enabled, the pixel values are compared to the ASCOLORKEYLOW and ASCOLORKEYHIGH registers to determine if a match has occurred. When an AS pixel matches the color key range, the pixel from the AS image is considered transparent and the corresponding PS pixel is rendered. If both the PS and AS pixels match their corresponding color key ranges, the AS pixel is displayed unmodified.

AS color keys are handled in a manner similar to PS color keys. The same images used in the PS color key example could be used with the images swapped. In this case, matches on the AS image to the ASCOLORKEY register would display the PS pixels.

## 35.5 Output Image Processing

Several PXP options affect the resulting output image.

### 35.5.1 Output Image Size

The PXP generates an output image in the resolution programmed by the REG\_OUT\_LRC. As the PXP processes pixels, it iterates over the NxN blocks (in output scan-block order) based on the final image resolution.

### 35.5.2 Output Format

The result of PXP operations are written to the buffer pointed to by the REG\_OUT\_BUF/REG\_OUT\_BUF2 registers. The pixel format is controlled by the REG\_OUT\_CTRL[FORMAT] bit-field.

32-bit pixels are formed directly from the internal 24-bit representations and 16-bit pixel formats are generated by truncating the internal 24-bit values to the appropriate number of bits. For formats supporting an alpha value, the PXP assigns the alpha using the 8-bit value in the REG\_OUT\_CTRL[ALPHA] field. For ARGB1555, the most significant alpha bit is appended to the output pixel. Also, for ARGB4444, the most significant nibble is appended to the output pixel. Single and dual buffer YUV output formats are also available. Since each pixel in the data path is represented by a full YUV444 24bpp value, decimation reduces the output in cases of YUV422/420 output formats.

### 35.5.3 Rotation/Flip operations

The PXP supports four rotation angles in conjunction with vertical and horizontal flip options. The flip operations effectively take place before the rotation.

Rotations of 0, 90, 180, and 270 degrees are supported and any combination of rotation and flip are supported. There is no performance difference between any of these modes of operation.

## 35.6 Queuing PXP transactions

The PXP supports a primitive ability to queue up one operation while the current operation is running. This is enabled through the use of the REG\_NEXT register.

When this register is written, it enables the PXP to reload its current register contents with the data found at the location pointed to by this address when it completes processing of the current frame. This feature may be useful in helping to reduce the interrupt latency in servicing the PXP, especially in cases where the PXP and LCDIF are using the on-chip SRAM buffer handshake (since the PXP must begin generating next frame data immediately).

If the PXP is idle when the REG\_NEXT register is written, the PXP treats this as an indication that it should immediately load the values at the pointer and begin processing the frame. This ability should allow software to use the same routines when programming the PXP (so that the first frame doesn't differ from subsequent frames).

When loading values from the NEXT register, all registers in the PXP are reloaded. Some register loads have no effect

After writing the REG\_NEXT register, the PXP will set the REG\_NEXT[ENABLED] bit of the REG\_NEXT register to indicate that the next command has been queued. Software should first check the status of this bit to ensure that a previous command has not been enabled. Likewise, after programming the first frame in a sequence of frames, software should poll this bit until it is sampled logic 1'b0 before queuing the next operation.

The PXP will issue interrupts from frames as they complete, regardless of whether they were started by writing the control registers directly or using the REG\_NEXT register. When software receives an interrupt, it should check/clear the PXP's status register as normal, poll the REG\_PXP[ENABLED] bit, and then issue the next operation. A queued operation may be cancelled by issuing a CLEAR operation to the REG\_PXP[ENABLED] register bit. The SET and TOGGLE operations should never be used with this register.

## 35.7 Error Handling

The PXP does minimal checking on the control registers, so it is important that these are correctly specified. The PXP does monitor the bus transactions for errors and will report errors in the status register.

Upon receipt of a bus error, the PXP will set the ERROR interrupt and abort any further operations. Bus errors can be generated from any system access that results in an error response returned from the internal SIM Bus errors in the PXP are signaled as either a read or a write error, but do not indicate the failing address. Software may deduce the failing address from the current block status indicators.

### 35.7.1 Known PXP Limitations/Issues

The PXP has the following known limitations:

1. When using the NEXT register, the interrupt enable setting should remain the same for all frames. If not, the PXP will change the interrupt enable register value and possible cause the loss of an interrupt.
2. Rotations of 180/270 are not supported when performing LCD handshakes

## 35.8 PXP Memory Map/Register Definition

PXP Hardware Register Format Summary

**PXP memory map**

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page

### 35.8.1 Control Register 0 (PXP\_CTRLn)

The CTRL register contains controls for the PXP module.

PXP\_CTRL: 0x000

PXP\_CTRL\_SET: 0x004

PXP\_CTRL\_CLR: 0x008

PXP\_CTRL\_TOG: 0x00C

The Control register contains the primary controls for the PXP block. The present bits indicate which of the sub-features of the block are present in the hardware.

#### EXAMPLE

```
PXP_CTRL_SET(BM_PXP_CTRL_SFTRST);
PXP_CTRL_CLR(BM_PXP_CTRL_SFTRST | BM_PXP_CTRL_CLKGATE);
```

# PXP Memory Map/Register Definition

Address: 402B\_4000h base + 0h offset + (4d × i), where i=0d to 3d

## PXP\_CTRLn field descriptions

Field	Description
31 SFTRST	Set this bit to zero to enable normal PXP operation. Set this bit to one (default) to disable clocking with the PXP and hold it in its reset (lowest power) state. This bit can be turned on and then off to reset the PXP block to its default state.
30 CLKGATE	This bit must be set to zero for normal operation. When set to one it gates off the clocks to the block.
29 RSVD4	Reserved, always set to zero.
28 EN_REPEAT	Enable the PXP to run continuously. When this bit is set, the PXP will repeat based on the current configuration register settings. If this bit is not set, the PXP will complete the process and enter the idle state ready to accept the next frame to be processed. This bit should be set when the LCDIF handshake mode is enabled so that the next frame is automatically generated for the next screen refresh cycle. If it not set and the handshake mode is enabled, the CPU will have to initiate the PXP for the next refresh cycle. When the PXP NEXT feature is used, it has priority over the REPEAT mode, in that the new register settings are fetched first, and then the next PXP operation will continue.
27–24 RSVD3	Reserved, always set to zero.
23 BLOCK_SIZE	Select the block size to process. 0x0 <b>8X8</b> — Process 8x8 pixel blocks. 0x1 <b>16X16</b> — Process 16x16 pixel blocks.
22 ROT_POS	This bit controls where rotation will occur in the PXP datapath. Setting this bit to 1'b0 will place the rotation resources at the output stage of the PXP data path. Image compositing will occur before pixels are processed for rotation. Setting this bit to a 1'b1 will place the rotation resources before image composition. Only the PS can be rotated in this configuration and AS will not be rotated.
21–12 RSVD1	Reserved, always set to zero.
11 VFLIP	Indicates that the output buffer should be flipped vertically (effect applied before rotation).
10 HFLIP	Indicates that the output buffer should be flipped horizontally (effect applied before rotation).
9–8 ROTATE	Indicates the clockwise rotation to be applied at the output buffer. The rotation effect is defined as occurring after the FLIP_X and FLIP_Y permutation. 0x0 <b>ROT_0</b> — 0x1 <b>ROT_90</b> — 0x2 <b>ROT_180</b> — 0x3 <b>ROT_270</b> —
7–5 Reserved	This read-only field is reserved and always has the value 0.
4 ENABLE_LCD_HANDSHAKE	Enable handshake with LCD controller. When this is set, the PXP will not process an entire framebuffer, but will instead process rows of NxN blocks in a double-buffer handshake with the LCDIF. This enables the use of the onboard SRAM for a partial frame buffer.
3 -	This field is reserved. Reserved
2 NEXT_IRQ_ENABLE	Next command interrupt enable. When set, the PXP will issue an interrupt when a queued command initiated by a write to the PXP_NEXT register has been loaded into the PXP's registers. This interrupt also indicates that a new command may now be queued.

Table continues on the next page...

**PXP\_CTRLn field descriptions (continued)**

Field	Description
1 IRQ_ENABLE	Interrupt enable. NOTE: When using the PXP_NEXT functionality to reprogram the PXP, the new value of this bit will be used and may therefore enable or disable an interrupt unintentionally.
0 ENABLE	Enables PXP operation with specified parameters. The ENABLE bit will remain set while the PXP is active and will be cleared once the current operation completes. Software should use the IRQ bit in the PXP_STAT when polling for PXP completion.

**35.8.2 Status Register (PXP\_STATn)**

The PXP Interrupt Status register provides interrupt status information.

PXP\_STAT: 0x010

PXP\_STAT\_SET: 0x014

PXP\_STAT\_CLR: 0x018

PXP\_STAT\_TOG: 0x01C

This register provides PXP interrupt status and the current X/Y block coordinate that is being processed.

**EXAMPLE**

```
PXP_STAT_CLR(BM_PXP_STAT_IRQ); // clear CSC interrupt
```

Address: 402B\_4000h base + 10h offset + (4d × i), where i=0d to 3d

PXP\_STATn field descriptions

Field	Description
31–24 BLOCKX	Indicates the X coordinate of the block currently being rendered.
23–16 BLOCKY	Indicates the Y coordinate of the block currently being rendered.
15–9 RSVD2	Reserved, always set to zero.
8 LUT_DMA_LOAD_DONE_IRQ	Indicates that the LUT DMA transfer has completed.
7–4 AXI_ERROR_ID	Indicates the AXI ID of the failing bus operation.
3 NEXT_IRQ	Indicates that a command issued with the "Next Command" functionality has been issued and that a new command may be initiated with a write to the PXP_NEXT register.
2 AXI_READ_ERROR	Indicates PXP encountered an AXI read error and processing has been terminated.
1 AXI_WRITE_ERROR	Indicates PXP encountered an AXI write error and processing has been terminated.
0 IRQ	Indicates current PXP interrupt status. The IRQ is routed through the pxp_irq when the IRQ_ENABLE bit in the control register is set.

### 35.8.3 Output Buffer Control Register (PXP\_OUT\_CTRLn)

The OUT\_CTRL register contains controls for the Output Buffer.

PXP\_OUT\_CTRL: 0x020

**PXP Memory Map/Register Definition**

PXP\_OUT\_CTRL\_SET: 0x024

PXP\_OUT\_CTRL\_CLR: 0x028

PXP\_OUT\_CTRL\_TOG: 0x02C

The Control register contains the primary controls for the PXP block. The present bits indicate which of the sub-features of the block are present in the hardware.

**EXAMPLE**

```
PXP_CTRL_SET(BM_PXP_CTRL_SFTRST);
PXP_CTRL_CLR(BM_PXP_CTRL_SFTRST | BM_PXP_CTRL_CLKGATE);
```

Address: 402B\_4000h base + 20h offset + (4d × i), where i=0d to 3d

## PXP\_OUT\_CTRLn field descriptions

Field	Description
31–24 ALPHA	When generating an output buffer with an alpha component, the value in this field will be used when enabled to override the alpha passed through the pixel data pipeline.
23 ALPHA_ OUTPUT	Indicates that alpha component in output buffer pixels should be overwritten by PXP_OUT_CTRL[ALPHA]. If 0, retain their alpha value from the computed alpha for that pixel.
22–10 RSVD1	Reserved, always set to zero.
9–8 INTERLACED_ OUTPUT	Determines how the PXP writes it's output data. Output interlacing should not be used in conjunction with input interlacing. Splitting frames into fields is most efficient using output interlacing. 2-plane output formats AND interlaced output is NOT supported.  0x0 <b>PROGRESSIVE</b> — All data written in progressive format to the OUTBUF Pointer. 0x1 <b>FIELD0</b> — Interlaced output: only data for field 0 is written to the OUTBUF Pointer. 0x2 <b>FIELD1</b> — Interlaced output: only data for field 1 is written to the OUTBUF2 Pointer. 0x3 <b>INTERLACED</b> — Interlaced output: data for field 0 is written to OUTBUF and data for field 1 is written to OUTBUF2.
7–5 RSVD0	Reserved, always set to zero.
FORMAT	Output framebuffer format. The UV byte lanes are synonymous with CbCr byte lanes for YUV output pixel formats. For example, the YUV2P420 format should be selected when the output is YCbCr 2-plane 420 output format.  0x0 <b>ARGB8888</b> — 32-bit pixels 0x4 <b>RGB888</b> — 32-bit pixels (unpacked 24-bit pixel in 32 bit DWORD.) 0x5 <b>RGB888P</b> — 24-bit pixels (packed 24-bit format) 0x8 <b>ARGB1555</b> — 16-bit pixels 0x9 <b>ARGB4444</b> — 16-bit pixels 0xC <b>RGB555</b> — 16-bit pixels 0xD <b>RGB444</b> — 16-bit pixels 0xE <b>RGB565</b> — 16-bit pixels 0x10 <b>YUV1P444</b> — 32-bit pixels (1-plane XYUV unpacked) 0x12 <b>UYVY1P422</b> — 16-bit pixels (1-plane U0,Y0,V0,Y1 interleaved bytes) 0x13 <b>VYUY1P422</b> — 16-bit pixels (1-plane V0,Y0,U0,Y1 interleaved bytes) 0x14 <b>Y8</b> — 8-bit monochrome pixels (1-plane Y luma output) 0x15 <b>Y4</b> — 4-bit monochrome pixels (1-plane Y luma, 4 bit truncation) 0x18 <b>YUV2P422</b> — 16-bit pixels (2-plane UV interleaved bytes) 0x19 <b>YUV2P420</b> — 16-bit pixels (2-plane UV) 0x1A <b>YVU2P422</b> — 16-bit pixels (2-plane VU interleaved bytes) 0x1B <b>YVU2P420</b> — 16-bit pixels (2-plane VU)

## 35.8.4 Output Frame Buffer Pointer (PXP\_OUT\_BUF)

Output Framebuffer Pointer. This register points to the beginning of the output frame buffer. This pointer is used for progressive format and field 0 when generating interlaced output.

## PXP Memory Map/Register Definition

This register is used by the logic to point to the current output location for the output frame buffer.

### EXAMPLE

```
PXP_OUT_BUF_WR( buffer );
```

Address: 402B\_4000h base + 30h offset = 402B\_4030h

### PXP\_OUT\_BUF field descriptions

Field	Description
ADDR	Current address pointer for the output frame buffer. The address can have any byte alignment. 64B alignment is recommended for optimal performance.

## 35.8.5 Output Frame Buffer Pointer #2 (PXP\_OUT\_BUF2)

Output Framebuffer Pointer #2. This register points to the beginning of the output frame buffer for either field 1 when generating interlaced output or for the UV buffer when in YUV 2-plane output modes. Both interlaced output AND 2-plane output modes are not supported in a single PXP operation. This register is not used as the pointer to the second buffer when in LCDIF\_HANDSHAKE mode.

This register is used by the logic to point to the current output location for the field 1 or UV output frame buffer.

### EXAMPLE

```
PXP_OUT_BUF_WR( field0 ); // buffer for interlaced field 0  
PXP_OUT_BUF2_WR( field1 ); // buffer for interlaced field 1
```

Address: 402B\_4000h base + 40h offset = 402B\_4040h

### PXP\_OUT\_BUF2 field descriptions

Field	Description
ADDR	Current address pointer for the output frame buffer. The address can have any byte alignment. 64B alignment is recommended for optimal performance.

### 35.8.6 Output Buffer Pitch (PXP\_OUT\_PITCH)

This register contains the output buffer pitch in bytes.

Any byte value will indicate the vertical pitch. This value will be used in output pixel address calculations.

#### EXAMPLE

```
PXP_OUT_PITCH_WR( 68 * 4 ); // The output buffer pitch is 68 pixels times 32 bits per pixel
```

Address: 402B\_4000h base + 50h offset = 402B\_4050h

#### PXP\_OUT\_PITCH field descriptions

Field	Description
31–16 RSVD	Reserved, always set to zero.
PITCH	Indicates the number of bytes in memory between two vertically adjacent pixels.

### 35.8.7 Output Surface Lower Right Coordinate (PXP\_OUT\_LRC)

This register contains the size, or lower right coordinate, of the output buffer NOT rotated. It is implied that the upper left coordinate of the output surface is always [0,0]. When rotating the framebuffer, the PXP will automatically swap the X/Y, or WIDTH/HEIGHT, to accommodate the rotated size.

This register sets the size of the output frame buffer in pixels, not blocks. The frame buffer need not be a multiple of NxN pixels. Partial blocks will be written for output frame buffer sizes that are not divisible by N pixels in either dimension.

#### EXAMPLE

```
PXP_OUT_LRC[X]=319; // set width of output frame buffer to 320 pixels
PXP_OUT_LRC[Y]=243; // set height of output frame buffer to 244 pixels which is not
divisible by block size N
```

```
PXP_OUT_LRC_WR( BF_PXP_OUT_LRC_X(319) | BF_PXP_OUT_LRC_Y(243) );
```

## PXP Memory Map/Register Definition

Address: 402B\_4000h base + 60h offset = 402B\_4060h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	RSVD1			X												
W	[Shaded]			[Shaded]												
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RSVD0			Y												
W	[Shaded]			[Shaded]												
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### PXP\_OUT\_LRC field descriptions

Field	Description
31–30 RSVD1	Reserved, always set to zero.
29–16 X	Indicates number of horizontal PIXELS in the output surface (non-rotated). The output buffer pixel width minus 1 should be programmed. The image size is not required to be a multiple of 8 pixels. The PXP will clip the pixel output at this boundary.
15–14 RSVD0	Reserved, always set to zero.
Y	Indicates the number of vertical PIXELS in the output surface (non-rotated). The output buffer pixel height minus 1 should be programmed. The image size is not required to be a multiple of 8 pixels. The PXP will clip the pixel output at this boundary.

## 35.8.8 Processed Surface Upper Left Coordinate (PXP\_OUT\_PS\_ULC)

This register contains the upper left pixel coordinate for the Processed Surface in the OUTPUT buffer.

This register contains the upper left coordinate of the Processed Surface in the output frame buffer (in pixels). Values that are within the PXP\_OUT\_LRC X,Y extents are valid. The lowest valid value for these fields is 0,0. If the value of the PXP\_OUT\_PS\_ULC is greater than the PXP\_OUT\_LRC, then no PS pixels will be fetched from memory, but only PXP\_PS\_BACKGROUND pixels will be processed by the PS engine. Pixel locations that are greater than or equal to the PS upper left coordinates, less than or equal to the PS lower right coordinates, and within the PXP\_OUT\_LRC extents will use the PS to render pixels into the output buffer.

### EXAMPLE

```
PXP_OUT_PS_ULC_WR(0,0x0002_0002); // Processed Surface upper left coordinate at (X,Y) = 2,2. The PS surface will not effect pixels in the first and second row and column of the output buffer.
```

Address: 402B\_4000h base + 70h offset = 402B\_4070h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	RSVD1			X												
W	[Shaded]			[Shaded]												
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RSVD0			Y												
W	[Shaded]			[Shaded]												
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### PXP\_OUT\_PS\_ULC field descriptions

Field	Description
31–30 RSVD1	Reserved, always set to zero.
29–16 X	This field indicates the upper left X-coordinate (in pixels) of the processed surface (PS) in the output buffer.
15–14 RSVD0	Reserved, always set to zero.
Y	This field indicates the upper left Y-coordinate (in pixels) of the processed surface in the output buffer.

## 35.8.9 Processed Surface Lower Right Coordinate (PXP\_OUT\_PS\_LRC)

This register contains the lower right extent for the Processed Surface in the OUTPUT buffer.

This register contains the lower right coordinate of the Processed Surface in the output frame buffer (in pixels). Values that are within the PXP\_OUT\_LRC X,Y extents are valid. The lowest valid value for these fields is 0,0. Pixel locations that are greater than or equal to the PS upper left coordinates, less than or equal to the PS lower right coordinates, and within the PXP\_OUT\_LRC extents will use the PS to render pixels into the output buffer.

### EXAMPLE

```
PXP_OUT_PS_ULC_WR(0,0x03FF_03FF); // With this UL/LR pair of pixel coordinates, only one
pixel at OUT[X,Y]=1023,1023 will use the PS to contribute to its value.
PXP_OUT_PS_LRC_WR(0,0x03FF_03FF);
```

## PXP Memory Map/Register Definition

### PXP\_OUT\_PS\_LRC field descriptions

Field	Description
31–30 RSVD1	Reserved, always set to zero.
29–16 X	This field indicates the lower right X-coordinate (in pixels) of the processed surface (PS) in the output frame buffer.
15–14 RSVD0	Reserved, always set to zero.
Y	This field indicates the lower right Y-coordinate (in pixels) of the processed surface in the output frame buffer.

## 35.8.10 Alpha Surface Upper Left Coordinate (PXP\_OUT\_AS\_ULC)

This register contains the upper left location for the Alpha Surface in the output buffer.

This register contains the upper left coordinate of AS in the output frame buffer (in pixels). Values that are within the PXP\_OUT\_LRC X,Y extents are valid. The lowest valid value for these fields is 0,0. Pixel locations that are greater than or equal to the upper left coordinates will use the AS to render pixels in the output buffer.

### EXAMPLE

```
PXP_OUT_AS_ULC_WR(0,0x0001_0001); // Alpha Surface upper left coordinate at (X,Y) = 1,1.
The AS surface will not effect pixels in the first row or first column of the output buffer.
```

Address: 402B\_4000h base + 90h offset = 402B\_4090h

Bit	31	30	29	28	27	26	25	24		23	22	21	20	19	18	17	16

### PXP\_OUT\_AS\_ULC field descriptions

Field	Description
31–30 RSVD1	Reserved, always set to zero.
29–16 X	This field indicates the upper left X-coordinate (in pixels) of the alpha surface (AS) in the output frame buffer.
15–14 RSVD0	Reserved, always set to zero.
Y	This field indicates the upper left Y-coordinate (in pixels) of the alpha surface in the output frame buffer.

### 35.8.11 Alpha Surface Lower Right Coordinate (PXP\_OUT\_AS\_LRC)

This register contains the lower right extent for Alpha Surface in the output buffer.

This register contains the lower right coordinate of AS in the output frame buffer (in pixels). Values that are within the PXP\_OUT\_LRC X,Y extents are valid. The lowest valid value for these fields is 0,0. Pixel locations that are less than or equal to the lower right coordinates will use the AS to render pixels in the output buffer.

#### EXAMPLE

```
PXP_AS_LRC_WR(0,0x03FF_03FF); // Alpha Surface lower right coordinate at (X,Y) = 1023,1023.
```

Address: 402B\_4000h base + A0h offset = 402B\_40A0h

Bit	31	30	29	28	27	26	25	24		23	22	21	20	19	18	17	16

**PXP\_OUT\_AS\_LRC field descriptions**

Field	Description
31–30 RSVD1	Reserved, always set to zero.
29–16 X	This field indicates the lower right X-coordinate (in pixels) of the alpha surface (AS) in the output frame buffer.
15–14 RSVD0	Reserved, always set to zero.
Y	This field indicates the lower right Y-coordinate (in pixels) of the alpha surface in the output frame buffer.

**35.8.12 Processed Surface (PS) Control Register (PXP\_PS\_CTRLn)**

The PS\_CTRL register contains controls for the Processed Surface Buffer.

PXP\_PS\_CTRL: 0x0B0

PXP\_PS\_CTRL\_SET: 0x0b4

PXP\_PS\_CTRL\_CLR: 0x0B8

PXP\_PS\_CTRL\_TOG: 0x0BC

The Control register contains the primary controls for the PXP block. The present bits indicate which of the sub-features of the block are present in the hardware.

**EXAMPLE**

```
PXP_CTRL_SET(BM_PXP_CTRL_SFTRST);
PXP_CTRL_CLR(BM_PXP_CTRL_SFTRST | BM_PXP_CTRL_CLKGATE);
```

Address: 402B\_4000h base + B0h offset + (4d × i), where i=0d to 3d

## PXP\_PS\_CTRLn field descriptions

Field	Description
31–12 RSVD1	Reserved, always set to zero.
11–10 DECX	Horizontal pre decimation filter control. 0x0 <b>DISABLE</b> — Disable pre-decimation filter. 0x1 <b>DECX2</b> — Decimate PS by 2. 0x2 <b>DECX4</b> — Decimate PS by 4. 0x3 <b>DECX8</b> — Decimate PS by 8.
9–8 DECY	Verticle pre decimation filter control. 0x0 <b>DISABLE</b> — Disable pre-decimation filter. 0x1 <b>DECY2</b> — Decimate PS by 2. 0x2 <b>DECY4</b> — Decimate PS by 4. 0x3 <b>DECY8</b> — Decimate PS by 8.
7–6 RSVD0	Reserved, always set to zero.
5 WB_SWAP	Swap bytes in words. For each 16 bit word, the two bytes will be swapped.
FORMAT	PS buffer format. To select between YUV and YCbCr formats, see bit 31 of the CSC1_COEF0 register. 0x4 <b>RGB888</b> — 32-bit pixels (unpacked 24-bit format) 0xC <b>RGB555</b> — 16-bit pixels 0xD <b>RGB444</b> — 16-bit pixels 0xE <b>RGB565</b> — 16-bit pixels 0x10 <b>YUV1P444</b> — 32-bit pixels (1-plane XYUV unpacked) 0x12 <b>UYVY1P422</b> — 16-bit pixels (1-plane U0,Y0,V0,Y1 interleaved bytes) 0x13 <b>VYUY1P422</b> — 16-bit pixels (1-plane V0,Y0,U0,Y1 interleaved bytes) 0x14 <b>Y8</b> — 8-bit monochrome pixels (1-plane Y luma output) 0x15 <b>Y4</b> — 4-bit monochrome pixels (1-plane Y luma, 4 bit truncation) 0x18 <b>YUV2P422</b> — 16-bit pixels (2-plane UV interleaved bytes) 0x19 <b>YUV2P420</b> — 16-bit pixels (2-plane UV) 0x1A <b>YVU2P422</b> — 16-bit pixels (2-plane VU interleaved bytes) 0x1B <b>YVU2P420</b> — 16-bit pixels (2-plane VU) 0x1E <b>YUV422</b> — 16-bit pixels (3-plane format) 0x1F <b>YUV420</b> — 16-bit pixels (3-plane format)

### 35.8.13 PS Input Buffer Address (PXP\_PS\_BUF)

PS Input Buffer Address. This should be programmed to the starting address of the RGB data or Y (luma) data for the PS plane.

This register contains the pointer to the Luma/RGB buffer. If the application requires an offset into the PS buffer, then this address can be set so that the desired offset is achieved. Any byte address is valid. For best performance, 64B alignment is recommended.

#### EXAMPLE

```
PXP_PS_BUF_WR(image_rgb); // RGB image
PXP_PS_BUF_WR(image_y); // Y (luma) image data
PXP_PS_UBUF_WR(image_u); // U (Cb) image data
PXP_PS_VBUF_WR(image_v); // V (Cr) image data
```

Address: 402B\_4000h base + C0h offset = 402B\_40C0h

#### PXP\_PS\_BUF field descriptions

Field	Description
ADDR	Address pointer for the PS RGB or Y (luma) input buffer.

### 35.8.14 PS U/Cb or 2 Plane UV Input Buffer Address (PXP\_PS\_UBUF)

PS Chroma (U/Cb/UV) Input Buffer Address. This register points to the beginning of the PS U/Cb input buffer. In two plane operation, this register points to the beginning of the PS UV chroma input buffer.

This register contains the pointer to the Chroma U/Cb or 2 plane UV buffer. This register is unused when processing 1-plane buffer formats. If the application requires an offset into the PS buffer, then this address can be set so that the desired offset is achieved. Any byte address is valid. For best performance, 64B alignment is recommended.

#### EXAMPLE

```
PXP_PS_BUF_WR(image_y); // Y (luma) image data
PXP_PS_UBUF_WR(image_u); // U (Cb) image data
PXP_PS_VBUF_WR(image_v); // V (Cr) image data
```

Address: 402B\_4000h base + D0h offset = 402B\_40D0h

**PXP\_PS\_UBUF field descriptions**

Field	Description
ADDR	Address pointer for the PS U/Cb or 2 plane UV Chroma input buffer.

**35.8.15 PS V/Cr Input Buffer Address (PXP\_PS\_VBUF)**

PS Chroma (V/Cr) Input Buffer Address. This register points to the beginning of the PS V/Cr input buffer. In one or two plane operation, this register is not used. In monochrome modes Y8 and Y4, the low 16 bits are used as the U/V data in the datapath instead of sourcing U/V data from external buffers. In this case, it represents a fixed value for U/V data.

This register contains the pointer to the Chroma V/Cr buffer. For Y8/Y4 modes, the low 16 bits are used as the monochrome U and V values in the data path. Bits [15:8] represent the U data byte, and bits [7:0] represent the V data byte. Other than with Y8/Y4 input buffer formats, this register is unused when processing 1 or 2-plane buffer formats. If the application requires an offset into the PS buffer, then this address can be set so that the desired offset is achieved. Any byte address is valid. For best performance, 64B alignment is recommended.

**EXAMPLE**

```
PXP_PS_BUF_WR(image_y); // Y (luma) image data
PXP_PS_UBUF_WR(image_u); // U (Cb) image data
PXP_PS_VBUF_WR(image_v); // V (Cr) image data
```

Address: 402B\_4000h base + E0h offset = 402B\_40E0h

**PXP\_PS\_VBUF field descriptions**

Field	Description
ADDR	Address pointer for the PS V/Cr Chroma input buffer.

### 35.8.16 Processed Surface Pitch (PXP\_PS\_PITCH)

This register contains the processed surface pitch in bytes.

Any byte value will indicate the vertical pitch of the PS source frame buffer. This value will be used in PS pixel address calculations. This value has no relation to the UL and LR registers. It specifies how many bytes are between two vertically adjacent pixels in the input PS surface. For multi-plane formats, the Y buffer pitch should be programmed. For 2-plane YUV422, the UV pitch is the same as the Y pitch. For 3-plane YUV422, the U and V pitch is 1/2 the Y pitch. For 2-plane YUV420, the UV pitch is 1/2 the Y pitch. For 3-plane YUV420, the U and V pitch is 1/4 the Y pitch. All source buffers should comply with these U and V resolution reductions with respect to their Y source buffers.

#### EXAMPLE

```
PXP_PS_PITCH_WR( 64 * 4 ); // The output buffer pitch is 64 pixels times 32 bits per pixel
```

Address: 402B\_4000h base + F0h offset = 402B\_40F0h

#### PXP\_PS\_PITCH field descriptions

Field	Description
31–16 RSVD	Reserved, always set to zero.
PITCH	Indicates the number of bytes in memory between two vertically adjacent pixels.

### 35.8.17 PS Background Color (PXP\_PS\_BACKGROUND)

PS Background Pixel Color. This register provides a pixel value used when processing pixels outside of the region specified by the PS Coordinate registers. This value can effectively be used to set the color of the letterboxing region around the PS image.

This register contains a pixel value to be used for any PS pixels that fall outside the PS extents. This is effectively a background or letterbox color. The CSC1 control and datapath pixel format should be considered when selecting the background color.

#### EXAMPLE

```

PXP_PS_BACKGROUND_WR(0x00000000); // letterbox is black
PXP_PS_BACKGROUND_WR(0x00800000); // letterbox is dark red
PXP_PS_BACKGROUND_WR(0x00008000); // letterbox is dark green
PXP_PS_BACKGROUND_WR(0x00000080); // letterbox is dark blue

```

Address: 402B\_4000h base + 100h offset = 402B\_4100h

### PXP\_PS\_BACKGROUND field descriptions

Field	Description
31–24 RSVD	Reserved, always set to zero.
COLOR	Background color (in 24bpp format) for any pixels not within the buffer range specified by the PS ULC/LRC.

### 35.8.18 PS Scale Factor Register (PXP\_PS\_SCALE)

PS Scale Factor. This register provides the scale factor for the PS buffer.

The maximum down scaling factor is 1/2 such that the output image in either axis is 1/2 the size of the source. The maximum up scaling factor is 2<sup>12</sup> for either axis. The reciprocal of the scale factor should be loaded into this register. To reduce the PS buffer by a factor of two in the output frame buffer, a value of 10.0000\_0000\_0000 should be loaded into this register. To scale up by a factor of 4, the value of 1/4, or 00.0100\_0000\_0000, should be loaded into this register. To scale up by 8/5, the value of 00.1010\_0000\_0000 should be loaded.

#### EXAMPLE

```

PXP_PS_SCALE_WR(0x10001000); // 1:1 scaling (0x1.000)
PXP_PS_SCALE_WR(0x08000800); // 2x scaling (0x0.800)
PXP_PS_SCALE_WR(0x20002000); // 1/2x scaling (0x2.000)

```

## PXP Memory Map/Register Definition

Address: 402B\_4000h base + 110h offset = 402B\_4110h

### PXP\_PS\_SCALE field descriptions

Field	Description
31 RSVD2	Reserved, always set to zero.
30–16 YSCALE	This is a two bit integer and 12 bit fractional representation (##.####_####_####) of the Y scaling factor for the PS source buffer. The maximum value programmed should be 2 since scaling down by a factor greater than 2 is not supported with the bilinear filter. Decimation and the bilinear filter should be used together to achieve scaling by more than a factor of 2.
15 RSVD1	Reserved, always set to zero.
XSCALE	This is a two bit integer and 12 bit fractional representation (##.####_####_####) of the X scaling factor for the PS source buffer. The maximum value programmed should be 2 since scaling down by a factor greater than 2 is not supported with the bilinear filter. Decimation and the bilinear filter should be used together to achieve scaling by more than a factor of 2.

## 35.8.19 PS Scale Offset Register (PXP\_PS\_OFFSET)

PS Scale Offset. This register provides the initial scale offset for the PS buffer.

The X and Y offset provides the ability to access the source image with a per sub-pixel granularity. This provides the capability to use all source pixels to effect the output PS image. The fixed offset values can be used for sub-pixel adjustments in the bilinear scaling filter. For example, when scaling an image down by a factor of 2, an initial offset of 0x0 would result in sub-sampling every other pixel. If a fixed offset of 0x800 (1/2), all pixels are used in scaling the final output pixel value. In this case, the first output pixel would be the sum of  $(1/2 * P0) + (1/2 * P1)$ . This fixed offset is applied after the decimation filter stage, and before the bilinear filter stage.

### EXAMPLE

```
PXP_PS_SCALE_WR(0x2000_2000); // 1/2x scaling (0x2.000)
PXP_PS_OFFSET_WR(0x0800_0800); // half-pixel offset in both X and Y to ensure averaging
versus pixel decimation
```

Address: 402B\_4000h base + 120h offset = 402B\_4120h

### PXP\_PS\_OFFSET field descriptions

Field	Description
31–28 RSVD2	Reserved, always set to zero.
27–16 YOFFSET	This is a 12 bit fractional representation (0.####_####_####) of the Y scaling offset. This represents a fixed pixel offset which gets added to the scaled address to determine source data for the scaling engine.
15–12 RSVD1	Reserved, always set to zero.
XOFFSET	This is a 12 bit fractional representation (0.####_####_####) of the X scaling offset. This represents a fixed pixel offset which gets added to the scaled address to determine source data for the scaling engine.

### 35.8.20 PS Color Key Low (PXP\_PS\_CLRKEYLOW)

This register contains the color key low value for the PS buffer.

When processing an image, if the PXP finds a pixel in the PS buffer with a color that falls in the range between PXP\_PS\_CLRKEYLOW and PXP\_PS\_CLRKEYHIGH, it will insert the pixel from the AS channel. If the current AS pixel is letterboxed or if the AS also matches its colorkey range, the PXP\_PS\_BACKGROUND color is passed down the pixel pipeline.

### EXAMPLE

## PXP Memory Map/Register Definition

```

// colorkey values between
PXP_PS_CLRKEYLOW_WR (0x008000); // medium green and
PXP_PS_CLRKEYHIGH_WR(0x00FF00); // light green

```

Address: 402B\_4000h base + 130h offset = 402B\_4130h

### PXP\_PS\_CLRKEYLOW field descriptions

Field	Description
31–24 RSVD1	Reserved, always set to zero.
PIXEL	Low range of color key applied to PS buffer. To disable PS colorkeying, set the low colorkey to 0xFFFFFFFF and the high colorkey to 0x000000.

## 35.8.21 PS Color Key High (PXP\_PS\_CLRKEYHIGH)

This register contains the color key high value for the PS buffer.

When processing an image, if the PXP finds a pixel in the PS buffer with a color that falls in the range between PXP\_PS\_CLRKEYLOW and PXP\_PS\_CLRKEYHIGH, it will insert the pixel from the AS channel. If the current AS pixel is letterboxed or if the AS also matches its colorkey range, the PXP\_PS\_BACKGROUND color is passed down the pixel pipeline.

### EXAMPLE

```

// colorkey values between
PXP_PS_CLRKEYLOW_WR (0x008000); // medium green and
PXP_PS_CLRKEYHIGH_WR(0x00FF00); // light green

```

Address: 402B\_4000h base + 140h offset = 402B\_4140h

## PXP\_PS\_CLRKEYHIGH field descriptions

Field	Description
31–24 RSVD1	Reserved, always set to zero.
PIXEL	High range of color key applied to PS buffer. To disable PS colorkeying, set the low colorkey to 0xFFFFFFFF and the high colorkey to 0x000000.

## 35.8.22 Alpha Surface Control (PXP\_AS\_CTRL)

This register contains buffer control for the Alpha Surface 0 input buffer.

The Alpha Surface Parameter register provides additional controls for AS.

**EXAMPLE**

```

u32 asparam;
  asparam = BF_PXP_ASPARAM_ENABLE      (1);
  asparam |= BF_PXP_ASPARAM_ALPHA_CTRL (BV_PXP_ASPARAM_ALPHA_CTRL_ROPs);
  asparam |= BF_PXP_ASPARAM_FORMAT     (BV_PXP_ASPARAM_FORMAT_ARGB8888);
  asparam |= BF_PXP_ASPARAM_ROP       (BV_PXP_ASPARAM_ROP_XORAS);
PXP_ASPARAM_WR(0,asparam); // enable alpha surface to perform XOR ROP using RGB8888 AS
pixel format

```

Address: 402B\_4000h base + 150h offset = 402B\_4150h

## PXP Memory Map/Register Definition

### PXP\_AS\_CTRL field descriptions

Field	Description
31–21 RSVD1	Reserved, always set to zero.
20 ALPHA_INVERT	Setting this bit to logic 0 will not alter the alpha value. A logic 1 will invert the alpha value and apply (1-alpha) for image composition.
19–16 ROP	Indicates a raster operation to perform when enabled. Raster operations are enabled through the ALPHA_CTRL field.  0x0 <b>MASKAS</b> — AS AND PS 0x1 <b>MASKNOTAS</b> — nAS AND PS 0x2 <b>MASKASNOT</b> — AS AND nPS 0x3 <b>MERGEAS</b> — AS OR PS 0x4 <b>MERGENOTAS</b> — nAS OR PS 0x5 <b>MERGEASNOT</b> — AS OR nPS 0x6 <b>NOTCOPYAS</b> — nAS 0x7 <b>NOT</b> — nPS 0x8 <b>NOTMASKAS</b> — AS NAND PS 0x9 <b>NOTMERGEAS</b> — AS NOR PS 0xA <b>XORAS</b> — AS XOR PS 0xB <b>NOTXORAS</b> — AS XNOR PS
15–8 ALPHA	Alpha modifier used when the ALPHA_MULTIPLY or ALPHA_OVERRIDE values are programmed in PXP_AS_CTRL[ALPHA_CTRL]. The output alpha value will either be replaced (ALPHA_OVERRIDE) or scaled (ALPHA_MULTIPLY) when selected.
7–4 FORMAT	Indicates the input buffer format for AS.  0x0 <b>ARGB8888</b> — 32-bit pixels with alpha 0x4 <b>RGB888</b> — 32-bit pixels without alpha (unpacked 24-bit format) 0x8 <b>ARGB1555</b> — 16-bit pixels with alpha

Table continues on the next page...

## PXP\_AS\_CTRL field descriptions (continued)

Field	Description
	0x9 <b>ARGB4444</b> — 16-bit pixels with alpha 0xC <b>RGB555</b> — 16-bit pixels without alpha 0xD <b>RGB444</b> — 16-bit pixels without alpha 0xE <b>RGB565</b> — 16-bit pixels without alpha
3 ENABLE_ COLORKEY	Indicates that colorkey functionality is enabled for this alpha surface. Pixels found in the alpha surface colorkey range will be displayed as transparent (the PS pixel will be used).
2–1 ALPHA_CTRL	Determines how the alpha value is constructed for this alpha surface. Indicates that the value in the ALPHA field should be used instead of the alpha values present in the input pixels.  0x0 <b>Embedded</b> — Indicates that the AS pixel alpha value will be used to blend the AS with PS. The ALPHA field is ignored. 0x1 <b>Override</b> — Indicates that the value in the ALPHA field should be used instead of the alpha values present in the input pixels. 0x2 <b>Multiply</b> — Indicates that the value in the ALPHA field should be used to scale all pixel alpha values. Each pixel alpha is multiplied by the value in the ALPHA field. 0x3 <b>ROPs</b> — Enable ROPs. The ROP field indicates an operation to be performed on the alpha surface and PS pixels.
0 RSVD0	Reserved, always set to zero.

## 35.8.23 Alpha Surface Buffer Pointer (PXP\_AS\_BUF)

Alpha Surface 0 Buffer Address Pointer. This register points to the beginning of the Alpha Surface 0 input buffer.

This register is used to indicate the base address of the AS buffer.

**EXAMPLE**

```
u32* alpha_ptr;
PXP_ASn_WR(0, alpha_ptr);
```

Address: 402B\_4000h base + 160h offset = 402B\_4160h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																																
W	ADDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

## PXP\_AS\_BUF field descriptions

Field	Description
ADDR	Address pointer for the alpha surface 0 buffer.

### 35.8.24 Alpha Surface Pitch (PXP\_AS\_PITCH)

This register contains the alpha surface pitch in bytes.

Any byte value will indicate the vertical pitch. This value will be used in AS pixel address calculations. This value has no relation to the UL and LR registers. It specifies how many bytes are between two vertically adjacent pixels in the input AS surface.

#### EXAMPLE

```
PXP_AS_PITCH_WR( 1920 * 4 ); // The output buffer pitch is HD resolution at 32 bits per pixel
```

Address: 402B\_4000h base + 170h offset = 402B\_4170h

#### PXP\_AS\_PITCH field descriptions

Field	Description
31–16 RSVD	Reserved, always set to zero.
PITCH	Indicates the number of bytes in memory between two vertically adjacent pixels.

### 35.8.25 Overlay Color Key Low (PXP\_AS\_CLRKEYLOW)

This register contains the color key low value for the AS buffer.

When processing an image, the if the PXP finds a pixel in the current overlay image with a color that falls in the range from the ASCOLORKEYLOW to ASCOLORKEYHIGH range, it will use the PS pixel value for that location. If no PS image is present or if the PS image also matches its colorkey range, the PS background color is used. Colorkey operations are higher priority than alpha or ROP operations.

#### EXAMPLE

```

// colorkey values between
PXP_AS_CLRKEYLOW_WR (0x000000); // black and
PXP_AS_CLRKEYHIGH_WR(0x800000); // medium red

```

Address: 402B\_4000h base + 180h offset = 402B\_4180h

**PXP\_AS\_CLRKEYLOW field descriptions**

Field	Description
31–24 RSVD1	Reserved, always set to zero.
PIXEL	Low range of RGB color key applied to AS buffer. Each overlay has an independent colorkey enable.

**35.8.26 Overlay Color Key High (PXP\_AS\_CLRKEYHIGH)**

This register contains the color key high value for the AS buffer.

When processing an image, the if the PXP finds a pixel in the current overlay image with a color that falls in the range from the ASCOLORKEYLOW to ASCOLORKEYHIGH range, it will use the PS pixel value for that location. If no PS image is present or if the PS image also matches its colorkey range, the PS background color is used. Colorkey operations are higher priority than alpha or ROP operations.

**EXAMPLE**

```

// colorkey values between
PXP_AS_CLRKEYLOW_WR (0x000000); // black and
PXP_AS_CLRKEYHIGH_WR(0x800000); // medium red

```

Address: 402B\_4000h base + 190h offset = 402B\_4190h

**PXP\_AS\_CLRKEYHIGH field descriptions**

Field	Description
31–24 RSVD1	Reserved, always set to zero.
PIXEL	High range of RGB color key applied to AS buffer. Each overlay has an independent colorkey enable.

### 35.8.27 Color Space Conversion Coefficient Register 0 (PXP\_CSC1\_COEF0)

This register contains color space conversion coefficients in two's complement notation.

The coefficient 0 register contains coefficients used in the color space conversion algorithm. The Y and UV offsets are added to the source buffer to normalize them before the conversion. C0 is the coefficient that is used to multiply the luma component of the data for all three RGB components.

#### EXAMPLE

```
// The equations used for Colorspace conversion are:
//   R = C0*(Y+YOFFSET) + C1(V+UV_OFFSET)
//   G = C0*(Y+YOFFSET) + C3(U+UV_OFFSET) + C2(V+UV_OFFSET)
//   R = C0*(Y+YOFFSET) + C4(U+UV_OFFSET)

PXP_CSCCOEF0_WR(0x04030000); // YUV coefficients: C0, Yoffset, UVoffset
PXP_CSCCOEF1_WR(0x01230208); // YUV coefficients: C1, C4
PXP_CSCCOEF2_WR(0x076B079b); // YUV coefficients: C2, C3
```

Address: 402B\_4000h base + 1A0h offset = 402B\_41A0h

PXP\_CSC1\_COEF0 field descriptions

Field	Description
31 YCBCR_MODE	Set to 1 when performing YCbCr conversion to RGB. Set to 0 when converting RGB to YUV data. This bit changes the behavior of the scaler when performing U/V scaling.
30 BYPASS	Bypass the CSC unit in the scaling engine. When set to logic 1, bypass is enabled and the output pixels will be in the YUV/YCbCr color space. When set to logic 0, the CSC unit is enabled and the pixels will be converted based on the programmed coefficients.
29 RSVD1	Reserved, always set to zero.
28–18 C0	Two's compliment Y multiplier coefficient. YUV=0x100 (1.000) YCbCr=0x12A (1.164)
17–9 UV_OFFSET	Two's compliment phase offset implicit for CbCr data. Generally used for YCbCr to RGB conversion. YCbCr=0x180, YUV=0x000 (typically -128 or 0x180 to indicate normalized -0.5 to 0.5 range)
Y_OFFSET	Two's compliment amplitude offset implicit in the Y data. For YUV, this is typically 0 and for YCbCr, this is typically -16 (0x1F0)

### 35.8.28 Color Space Conversion Coefficient Register 1 (PXP\_CSC1\_COEF1)

This register contains color space conversion coefficients in two's compliment notation.

The Coefficient 1 register contains coefficients used in the color space conversion algorithm. C1 is the coefficient that is used to multiply the chroma (Cr/V) component of the data for the red component. C4 is the coefficient that is used to multiply the chroma (Cb/U) component of the data for the blue component. Both values should be coded as a two's compliment fixed point number with 8 bits right of the decimal.

#### EXAMPLE

```
PXP_CSCCOEF0_WR(0x04030000); // YUV coefficients: C0, Yoffset, UVoffset
PXP_CSCCOEF1_WR(0x01230208); // YUV coefficients: C1, C4
PXP_CSCCOEF2_WR(0x076B079b); // YUV coefficients: C2, C3
```

## PXP Memory Map/Register Definition

Address: 402B\_4000h base + 1B0h offset = 402B\_41B0h

### PXP\_CSC1\_COEF1 field descriptions

Field	Description
31–27 RSVD1	Reserved, always set to zero.
26–16 C1	Two's compliment Red V/Cr multiplier coefficient. YUV=0x123 (1.140) YCbCr=0x198 (1.596)
15–11 RSVD0	Reserved, always set to zero.
C4	Two's compliment Blue U/Cb multiplier coefficient. YUV=0x208 (2.032) YCbCr=0x204 (2.017)

## 35.8.29 Color Space Conversion Coefficient Register 2 (PXP\_CSC1\_COEF2)

This register contains color space conversion coefficients in two's compliment notation.

The Coefficient 2 register contains coefficients used in the color space conversion algorithm. C2 is the coefficient that is used to multiply the chroma (Cr/V) component of the data for the green component. C3 is the coefficient that is used to multiply the chroma (Cb/U) component of the data for the green component. Both values should be coded as a two's compliment fixed point number with 8 bits right of the decimal.

### EXAMPLE

// NOTE: The default values for the CSCCOEF2 register are incorrect. C2 should be 0x76B and C3 should be 0x79C for proper operation.

```
PXP_CSCCOEF0_WR(0x04030000); // YUV coefficients: C0, Yoffset, UYoffset
PXP_CSCCOEF1_WR(0x01230208); // YUV coefficients: C1, C4
PXP_CSCCOEF2_WR(0x076B079b); // YUV coefficients: C2, C3
```

Address: 402B\_4000h base + 1C0h offset = 402B\_41C0h

## PXP\_CSC1\_COEF2 field descriptions

Field	Description
31–27 RSVD1	Reserved, always set to zero.
26–16 C2	Two's complement Green V/Cr multiplier coefficient. YUV=0x76B (-0.581) YCbCr=0x730 (-0.813)
15–11 RSVD0	Reserved, always set to zero.
C3	Two's complement Green U/Cb multiplier coefficient. YUV=0x79C (-0.394) YCbCr=0x79C (-0.392)

## 35.8.30 PXP Power Control Register (PXP\_POWER)

This register controls power states for PXP memories.

Address: 402B\_4000h base + 320h offset = 402B\_4320h

## PXP\_POWER field descriptions

Field	Description
31–12 CTRL	Power control for the PXP.
11–9 ROT_MEM_LP_STATE	Select the low power state of the ROT memory. 0x0 <b>NONE</b> — Memory is not in low power state. 0x1 <b>LS</b> — Light Sleep Mode. Low leakage mode, maintain memory contents. 0x2 <b>DS</b> — Deep Sleep Mode. Low leakage mode, maintain memory contents. 0x4 <b>SD</b> — Shut Down Mode. Shut Down periphery and core, no memory retention.
Reserved	This read-only field is reserved and always has the value 0.

## 35.8.31 Next Frame Pointer (PXP\_NEXT)

This register contains a pointer to a data structure used to reload the PXP registers at the end of the current frame.

To enable this functionality, software must write this register while the PXP is processing the current data frame (if the PXP is currently idle, this will also initiate an immediate load of registers from the pointer). The process of writing this register (WRITE operation) will set a semaphore in hardware to notify the control logic that a register

reload operation must be performed when the current frame processing is complete. At the end of a frame, the PXP will fetch the register settings from this location, signal an interrupt to software, then proceed with rendering the next frame of data. Software may cancel the reload operation by issuing a CLEAR operation to this register. SET and TOGGLE operations should not be used when addressing this register. All registers will be reloaded with the exception of the following: STAT, CSCCOEFn, NEXT. All other registers will be loaded in the order they appear in the register map. Once the pointer's contents have been loaded into the PXP's registers, the NEXT\_IRQ interrupt will be issued (see the PXP\_STATUS register).

**EXAMPLE**

```
// create register command structure in memory
u32* pxp_commands0[48], pxp_commands1;
u32 rc;

// initialize control structure for frame 0
pxp_commands0[0] = ...; // CTRL
pxp_commands0[1] = ...; // OUT Buffer
...
pxp_commands0[47] = ..; // Overlay7 param2

// initialize control structure for frame 1
pxp_commands1[0] = ...; // CTRL
pxp_commands1[1] = ...; // OUT Buffer
...
pxp_commands1[47] = ..; // Overlay7 param2

// poll until a command isn't queued
while (rc=PXP_NEXT_RD() & BM_PXP_NEXT_ENABLED );
PXP_NEXT_WR(pxp_commands0); // enable PXP operation 0 via command pointer

// poll until first command clears
while (rc=PXP_NEXT_RD() & BM_PXP_NEXT_ENABLED );
PXP_NEXT_WR(pxp_commands1); // enable PXP operation 1 via command pointer
```

Address: 402B\_4000h base + 400h offset = 402B\_4400h

**PXP\_NEXT field descriptions**

Field	Description
31–2 POINTER	A pointer to a data structure containing register values to be used when processing the next frame. The pointer must be 32-bit aligned and should reside in on-chip or off-chip memory.
1 RSVD	Reserved, always set to zero.
0 ENABLED	Indicates that the "next frame" functionality has been enabled. This bit reflects the status of the hardware semaphore indicating that a reload operation is pending at the end of the current frame.

### 35.8.32 PXP Alpha Engine A Control Register. (PXP\_PORTER\_DUFF\_CTRL)

Address: 402B\_4000h base + 440h offset = 402B\_4440h

**PXP\_PORTER\_DUFF\_CTRL field descriptions**

Field	Description
31–24 S1_GLOBAL_ALPHA	s1 global alpha
23–16 S0_GLOBAL_ALPHA	s0 global alpha
15–14 Reserved	This read-only field is reserved and always has the value 0.
13 S1_COLOR_MODE	s1 color mode
12 S1_ALPHA_MODE	s1 alpha mode
11–10 S1_GLOBAL_ALPHA_MODE	s1 global alpha mode
9–8 S1_S0_FACTOR_MODE	s1 to s0 factor mode

Table continues on the next page...

**PXP\_PORTER\_DUFF\_CTRL field descriptions (continued)**

<b>Field</b>	<b>Description</b>
7 Reserved	This read-only field is reserved and always has the value 0.
6 S0_COLOR_ MODE	s0 color mode
5 S0_ALPHA_ MODE	s0 alpha mode
4–3 S0_GLOBAL_ ALPHA_MODE	s0 global alpha mode
2–1 S0_S1_ FACTOR_MODE	s0 to s1 factor mode
0 POTER_DUFF_ ENABLE	poter_duff enable

---

## Chapter 36

# Audio Overview

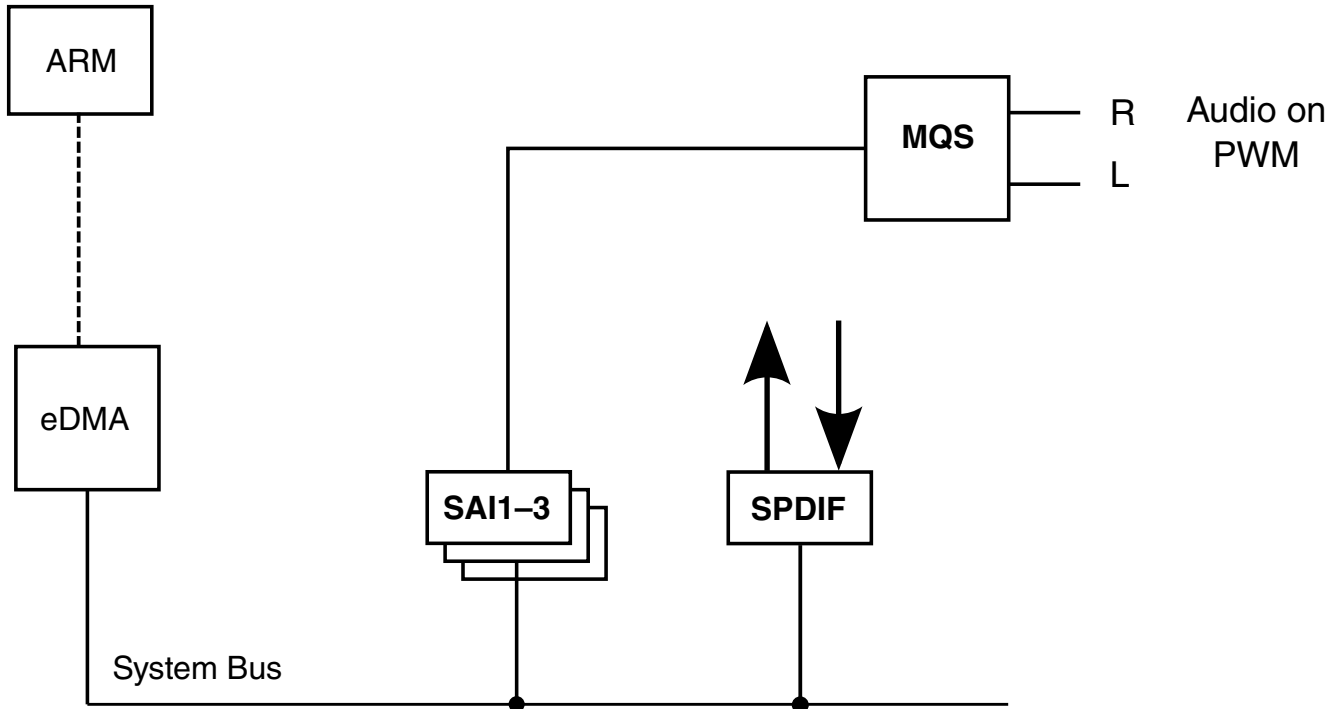

### 36.1 Audio Overview

The audio subsystem consists of the following modules: SAI-1, SAI-2, SAI-3, SPDIF and MQS. In addition, the IOMUX must be appropriately configured to get signals in and out of the chip.

[Audio Module Overview](#) provides an overview of each of the audio modules, followed by a module-specific section.

#### 36.1.1 Audio Module Overview

The following figure shows a high level block diagram of the audio subsystem.

**Figure 36-1. Audio subsystem block diagram**

SAI1–3 are synchronous serial interfaces used to transfer audio data. They can be accessed by both the eDMA and ARM CPUs. Their input/output are connected to the pads through IOMUX.

MQS (medium quality speaker) is used to convert the I2S audio data from SAI to PWM signals that can drive external speaker directly. Its audio source comes from SAI-3 and its output is connected to pads through IOMUX.

The SPDIF (Sony/Philips digital interface) audio module is a stereo transceiver that allows the processor to receive and transmit digital audio over it. The SPDIF receiver section includes a frequency measurement block that allows the precise measurement of an incoming sampling frequency. A recovered clock is provided by the SPDIF receiver section and may be used to drive both internal and external components in the system.

The audio interfaces are summarized as the table below.

**Table 36-1. Audio Interface Summary**

Interface	Function	RX Data Line	TX Data Line
SAI-1	External audio	4	4
SAI-2	External audio	1	1
SAI-3	External audio	1	1
MQS	External audio	0	2

*Table continues on the next page...*

**Table 36-1. Audio Interface Summary (continued)**

Interface	Function	RX Data Line	TX Data Line
SPDIF	External audio	1	1

SAI-1 is used for multi-channel audio interface, which supports up to 8-channels audio input or 8-channels audio output at 384 kHz/32-bit. SAI-2 and SAI-3 can be used for stereo audio input and output up to 384 kHz/32-bit. Also SAI-3 is able to drive MQS directly as a low-cost audio output.

To reduce IO count and keep the flexibilities of supporting multiple RX and TX data lines application, SAI-1 has following options on data pin multiplexing.

**Table 36-2. SAI-1 TX/RX Data Multiplexing**

Options	RX Data Line	TX Data Line
0	1	4
1	2	3
2	3	2
3	4	1

SAI-1 to IOMUXC connection is implemented as shown in the diagram below.

**Figure 36-2. SAI-1 TX/RX Data Multiplexing**

Detailed clock multiplexing scheme is shown in the following figure.

## Audio Overview

Figure 36-3. Audio subsystem clocking diagram

### 36.1.2 Medium Quality Sound (MQS)

MQS is used to generate medium quality audio via a standard GPIO in the pinmux. The user can connect stereo speakers or headphones to a power amplifier without an additional DAC chip.

- 2-channel, LSB-valid 16 bit, MSB shift-out first serial data (sdata)
- Frame sync aligned with the left channel data
- 44 kHz or 48 kHz I2S signals from SAI3

- SNR target as no more than 20 dB for the signals below 10 kHz
- Signals over 10 kHz have worse THD+N values

### 36.1.3 Synchronous Audio Interface (SAI)

- Transmitter with independent Bit Clock and Frame Sync supporting 1 data line
- Receiver with independent Bit Clock and Frame Sync supporting 1 data line
- Maximum Frame Size of 32 Words
- Word size programmable from 8-bits to 32-bits
- Word size configured separately for first word and remaining words in frame
- Asynchronous FIFO for each Transmit and Receive data line
- Graceful restart after FIFO Error

### 36.1.4 Sony/Philips Digital Interface (SPDIF)

The Sony/Philips Digital Interface (SPDIF) module is a stereo transceiver that allows the processor to receive and transmit digital audio over it using the IEC60958 standard, consumer format. The chip provides a single SPDIF receiver with one input, and one SPDIF transmitter with one output.

The SPDIF transceiver allows the handling of both SPDIF channel status (CS) and User (U) data and features a frequency measurement block that allows the precise measurement of the incoming sampling frequency.

The clock recovered by the SPDIF receiver is provided to drive both internal and external components in the system such as the SPDIF transmitter, ESAI ports, as well as external A/Ds or D/As, with clocking control provided via related registers.

The SPDIF is composed of two parts: SPDIF Receiver and SPDIF Transmitter. The SPDIF receiver extracts the audio data from each SPDIF frame and places the data in two 16-word-deep FIFOs, one FIFO for the left channel, the other FIFO for the right channel. The FIFOs support programmable watermark levels so that FIFO Full service request can be triggered when the combined number of data words stored in both FIFOs is 2, 8, 16 or 32 words. It is recommended to program the watermark level to trigger a FIFO Full service request when 16 word locations are filled. For optimal performance when servicing the FIFO Full service request, the FIFOs should be read alternately, starting with the left channel FIFO. The Channel Status and User Bits are also extracted from each frame and placed in the corresponding registers. The SPDIF receiver provides a bypass option for direct transfer of the SPDIF input signal to the SPDIF transmitter.

For the SPDIF transmitter, the audio data is provided by the processor via the SPDIFTxLeft and SPDIFTxRight registers, and the data is stored in two 16-word-deep FIFOs, one for the right channel, the other for the left channel. The FIFOs support programmable watermark levels so that FIFO Empty service request can be triggered when the combined number of empty data words locations in both FIFOs is 8, 16, 24 or 32 words. It is recommended to program the watermark level to trigger a FIFO Empty service request when 16 word locations are empty. For optimal performance when servicing the FIFO Empty service request, the FIFOs should be written alternately, starting with the left channel FIFO. The Channel Status bits are also provided via the corresponding registers. The SPDIF transmitter generates an SPDIF output bitstream in the biphase mark format (IEC 60958), which consists of audio data, channel status and user bits.

The data handled by the SPDIF module is 24-bit wide. The 24-bit SPDIF data is aligned in the 24 least significant bits of the 32-bit shared peripheral bus data word. The 8 most significant bits of the 32-bit word are ignored by the SPDIF Transmitter when data is being stored in the Transmit FIFOs from the peripheral bus. The 8 most significant bits of the 32-bit word are zeroed by the SPDIF Receiver module when the data is being read from the Receiver FIFOs to the peripheral bus.

Note that 16-bit data is left-aligned in the 24-bit word format of the SPDIF. This means that when receiving 16-bit data, it will be located in the middle two bytes of the 32-bit peripheral bus data word, while the 8 bits of the MSB and the 8 bits of the LSB will be zero. When 16-bit data is to be transmitted, the 32-bit word to be written to the SPDIF Transmit FIFOs should be created as follows: the 16-bit data should be located in the middle two bytes of the 32-bit data word and the 8 bits of the LSB must be set to zero, while the 8 bits of the MSB will be ignored.

The SPDIF Transmit clock is generated by the SPDIF internal clock generator module and the clock sources are from outside of the SPDIF block. The clock sources should provide a clock that is at least  $64 \times F_s$ , where  $F_s$  is the sampling frequency. The external clock source should provide at least  $128 \times F_s$ . Clocks of higher frequency may be provided as long as the multiplication factor is a power of 2 (for example,  $128x$ ,  $256x$  or  $512x$ ). Also, clock frequency precision of 100ppm or better should be provided.

# Chapter 37

## Synchronous Audio Interface (SAI)

### 37.1 Chip-specific SAI information

Table 37-1. Reference links to related information

Topic	Related module or subsystem	Reference

#### NOTE

Number of TX and RX data lines for SAI1 and SAI2/SAI3 are 4, and 1 respectively.

#### NOTE

For more details about the features and clocking of different SAI instances, see the [Audio Subsystem Overview](#) section of the Multimedia chapter.

### 37.2 Introduction

The I<sup>2</sup>S (or I2S) module provides a synchronous audio interface (SAI) that supports full-duplex serial interfaces with frame synchronization such as I<sup>2</sup>S, AC97, TDM, and codec/DSP interfaces.

## 37.2.1 Features

Note that some of the features are not supported across all SAI instances; see the chip-specific information in the first section of this chapter.

- Transmitter with independent bit clock and frame sync supporting 1 data line
- Receiver with independent bit clock and frame sync supporting 1 data line
- Each data line can support a maximum Frame size of 32 words
- Word size of between 8-bits and 32-bits
- Word size configured separately for first word and remaining words in frame
- Asynchronous 32 x 32-bit FIFO for each transmit and receive data line
- Supports graceful restart after FIFO error
- Supports automatic restart after FIFO error without software intervention
- Supports packing of 8-bit and 16-bit data into each 32-bit FIFO word

## 37.2.2 Block diagram

The following block diagram also shows the module clocks.

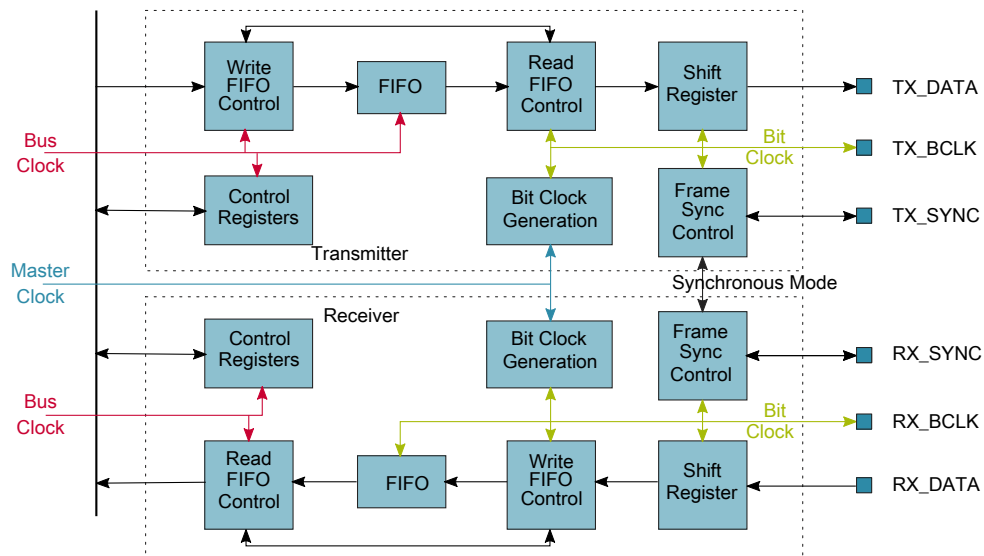

Figure 37-1. I<sup>2</sup>S/SAI block diagram

### 37.2.3 Modes of operation

Module power modes include Run mode, Stop modes, and Debug mode.

#### 37.2.3.1 Run mode

In Run mode, the SAI transmitter and receiver operate normally.

#### 37.2.3.2 Stop modes

In Stop mode, the SAI transmitter and/or receiver can continue operating provided the appropriate Stop Enable bit is set (TCSR[STOPE] and/or RCSR[STOPE], respectively), and provided the transmitter and/or receiver is/are using an externally generated bit clock or an Audio Master Clock that remains operating in Stop mode. The SAI transmitter and/or receiver can generate an asynchronous interrupt to wake the CPU from Stop mode.

In Stop mode, if the Transmitter Stop Enable (TCSR[STOPE]) bit is clear, the transmitter is disabled after completing the current transmit frame, and, if the Receiver Stop Enable (RCSR[STOPE]) bit is clear, the receiver is disabled after completing the current receive frame. Entry into Stop mode is prevented (not acknowledged) while waiting for the transmitter and receiver to be disabled at the end of the current frame.

#### 37.2.3.3 Debug mode

In Debug mode, the SAI transmitter and/or receiver can continue operating provided the Debug Enable bit is set. When TCSR[DBGE] or RCSR[DBGE] bit is clear and Debug mode is entered, the SAI is disabled after completing the current transmit or receive frame. The transmitter and receiver bit clocks are not affected by Debug mode.

## 37.3 External signals

Name	Function	I/O
TX_BCLK	Transmit Bit Clock. The bit clock is an input when externally generated and an output when internally generated.	I/O
TX_SYNC	Transmit Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated and an output generated	I/O

*Table continues on the next page...*

## Functional description

Name	Function	I/O
	synchronously by the bit clock when internally generated.	
TX_DATA[0:0]	Transmit Data. The transmit data is generated synchronously by the bit clock and is tristated whenever not transmitting a word.	O
RX_BCLK	Receive Bit Clock. The bit clock is an input when externally generated and an output when internally generated.	I/O
RX_SYNC	Receive Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated and an output generated synchronously by the bit clock when internally generated.	I/O
RX_DATA[0:0]	Receive Data. The receive data is sampled synchronously by the bit clock.	I

## 37.4 Functional description

This section provides a complete functional description of the block.

### 37.4.1 SAI clocking

The SAI clocks include:

- The audio master clock
- The bit clock
- The bus clock

#### 37.4.1.1 Audio master clock

The audio master clock is used to generate the bit clock when the receiver or transmitter is configured for an internally generated bit clock. The transmitter and receiver can independently select between the bus clock and up to three audio master clocks to generate the bit clock.

The audio master clock generation and selection is chip-specific. Refer to chip-specific clocking information about how the audio master clocks are generated.

### 37.4.1.2 Bit clock

The SAI transmitter and receiver support asynchronous free-running bit clocks that can be generated internally from an audio master clock or supplied externally. There is also the option for synchronous bit clock and frame sync operation between the receiver and transmitter or between multiple SAI peripherals.

- If both transmitter and receiver are configured for asynchronous operation, then the transmitter and receiver will each use *their own* bit clock and frame sync.
- If the *transmitter* is configured for asynchronous mode and the receiver is configured for synchronous mode, then both transmitter and receiver will use the *transmitter* bit clock and frame sync.
- If the *receiver* is configured for asynchronous mode and the transmitter is configured for synchronous mode, then both transmitter and receiver will use the *receiver* bit clock and frame sync.

Note that the software configures synchronous or asynchronous mode, and that choice selects the bit clock/frame sync used.

Externally generated bit clocks must be:

- Enabled before the SAI transmitter or receiver is enabled
- Disabled after the SAI transmitter or receiver is disabled and completes its current frames

If the SAI transmitter or receiver is using an externally generated bit clock in asynchronous mode and that bit clock is generated by an SAI that is disabled in stop mode, then the transmitter or receiver should be disabled by software before entering stop mode. This issue does not apply when the transmitter or receiver is in a synchronous mode because all synchronous SAIs are enabled and disabled simultaneously.

### 37.4.1.3 Bus clock

The bus clock is used by the control and configuration registers and to generate synchronous interrupts and DMA requests.

#### NOTE

Although there is no specific minimum bus clock frequency specified, the bus clock frequency must be fast enough (relative to the bit clock frequency) to ensure that the FIFOs can be serviced, without generating either a transmitter FIFO underrun or receiver FIFO overflow condition.

## 37.4.2 SAI resets

The SAI is asynchronously reset on system reset. The SAI has a software reset and a FIFO reset.

### 37.4.2.1 Software reset

The SAI transmitter includes a software reset that resets all transmitter internal logic, including the bit clock generation, status flags, and FIFO pointers. It does not reset the configuration registers. The software reset remains asserted until cleared by software.

The SAI receiver includes a software reset that resets all receiver internal logic, including the bit clock generation, status flags and FIFO pointers. It does not reset the configuration registers. The software reset remains asserted until cleared by software.

### 37.4.2.2 FIFO reset

The SAI transmitter includes a FIFO reset that synchronizes the FIFO write pointer to the same value as the FIFO read pointer. This empties the FIFO contents and is to be used after TCSR[FEF] is set, and before the FIFO is re-initialized and TCSR[FEF] is cleared. The FIFO reset is asserted for one cycle only.

The SAI receiver includes a FIFO reset that synchronizes the FIFO read pointer to the same value as the FIFO write pointer. This empties the FIFO contents and is to be used after the RCSR[FEF] is set and any remaining data has been read from the FIFO, and before the RCSR[FEF] is cleared. The FIFO reset is asserted for one cycle only.

## 37.4.3 Synchronous modes

The SAI transmitter and receiver can operate synchronously to each other or synchronously to other SAI peripherals.

### 37.4.3.1 Synchronous mode

The SAI transmitter and receiver can be configured to operate with synchronous bit clock and frame sync.

If the transmitter bit clock and frame sync are to be used by both the transmitter and receiver:

- The transmitter must be configured for asynchronous operation and the receiver for synchronous operation.
- In synchronous mode, the receiver is enabled only when both the transmitter and receiver are enabled.
- It is recommended that the transmitter is the last enabled and the first disabled.

If the receiver bit clock and frame sync are to be used by both the transmitter and receiver:

- The receiver must be configured for asynchronous operation and the transmitter for synchronous operation.
- In synchronous mode, the transmitter is enabled only when both the receiver and transmitter are both enabled.
- It is recommended that the receiver is the last enabled and the first disabled.

When operating in synchronous mode, only the bit clock, frame sync, and transmitter/receiver enable are shared. The transmitter and receiver otherwise operate independently, although configuration registers must be configured consistently across both the transmitter and receiver.

### 37.4.3.2 Multiple SAI Synchronous mode

Synchronous operation between multiple SAI peripherals is not supported on all devices. This mode requires the source of the bit clock and frame sync to be configured for asynchronous operation and the remaining users of the bit clock and frame sync to be configured for synchronous operation.

Synchronous operation between multiple SAI transmitters or receivers also requires the source of the bit clock and frame sync to be enabled for any of the synchronous transmitters or receivers to also be enabled. It is recommended that the source of the bit clock and frame sync is the last enabled and the first disabled.

When operating in synchronous mode, only the bit clock, frame sync, and transmitter/receiver enable are shared. The separate SAI peripherals otherwise operate independently, although configuration registers must be configured consistently across both the transmitter and receiver.

## 37.4.4 Frame sync configuration

When enabled, the SAI continuously transmits and/or receives frames of data. Each frame consists of a fixed number of words and each word consists of a fixed number of bits. Within each frame, any given word can be masked causing the receiver to ignore that word and the transmitter to tri-state for the duration of that word.

The frame sync signal is used to indicate the start of each frame. A valid frame sync requires a rising edge (if active high) or falling edge (if active low) to be detected and the transmitter or receiver cannot be busy with a previous frame. A valid frame sync is also ignored (slave mode) or not generated (master mode) for the first four bit clock cycles after enabling the transmitter or receiver.

The transmitter and receiver frame sync can be configured independently with any of the following options:

- Externally generated or internally generated
- Active high or active low
- Assert with the first bit in frame or asserts one bit early
- Assert for a duration between 1 bit clock and the first word length
- Frame length from 1 to 32 words per frame
- Word length to support 8 to 32 bits per word
  - First word length and remaining word lengths can be configured separately
- Words can be configured to transmit/receive MSB first or LSB first

These configuration options cannot be changed after the SAI transmitter or receiver is enabled.

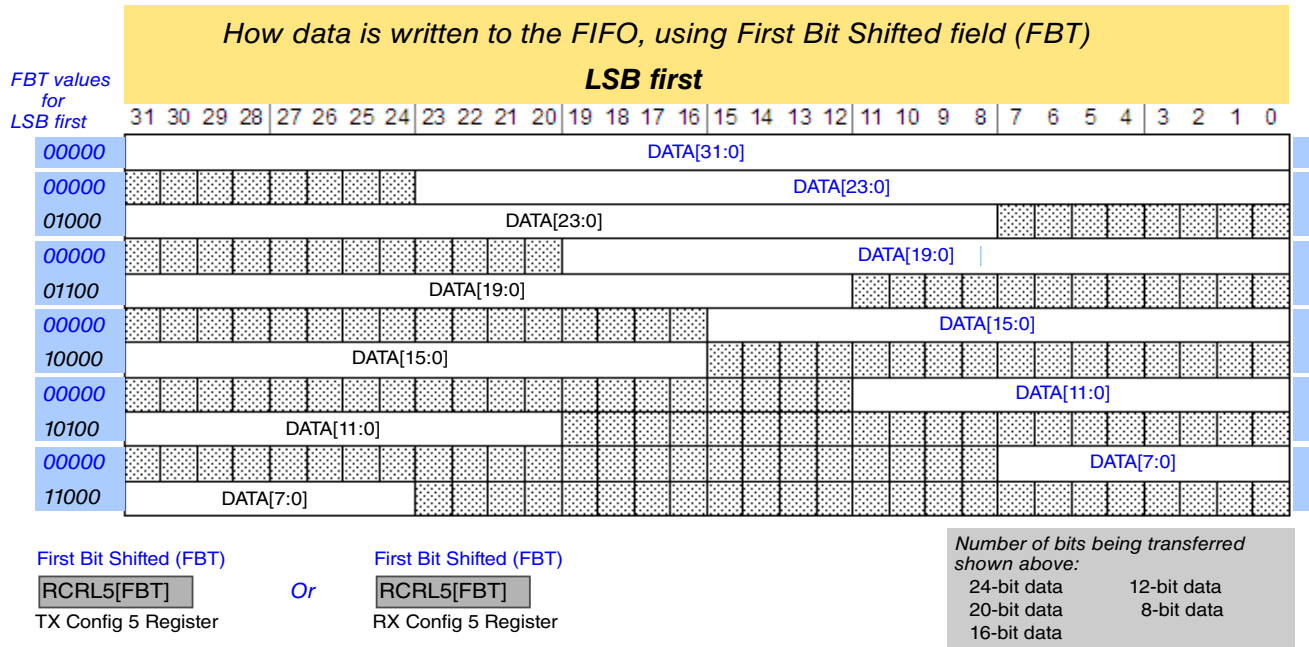

## 37.4.5 Data FIFO

Each transmit and receive channel includes a FIFO of size 32 x 32-bit. The FIFO data is accessed using the SAI Transmit/Receive Data Registers.

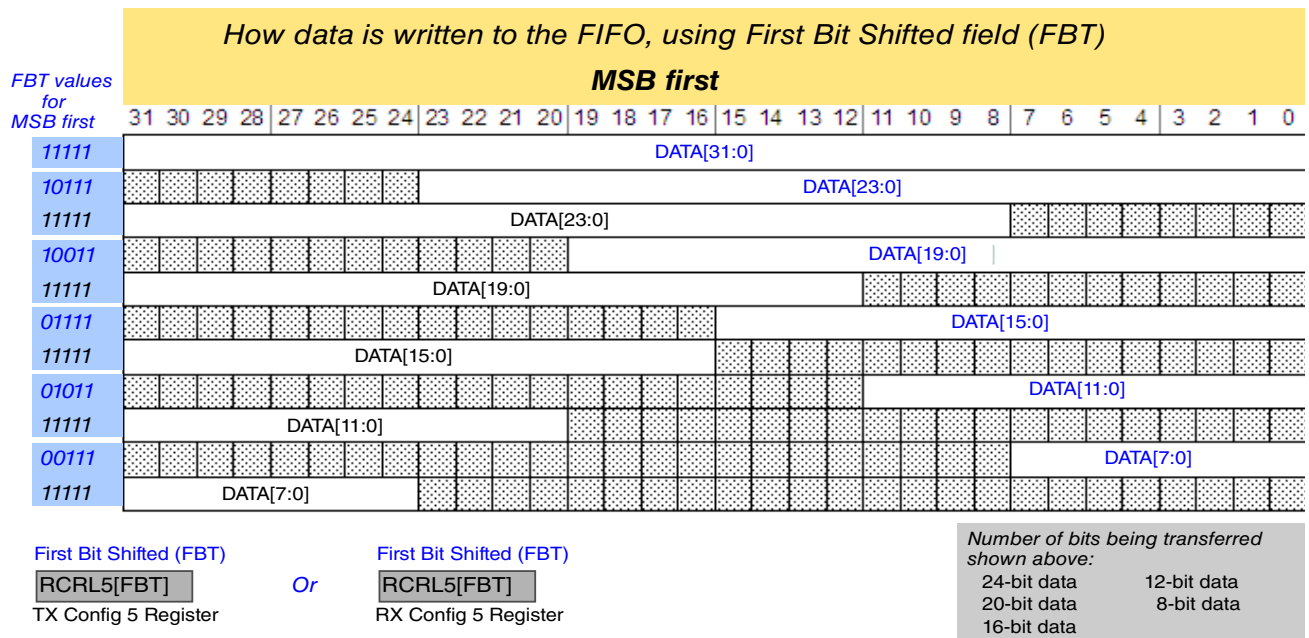

### 37.4.5.1 Data alignment

Data in the FIFO can be aligned anywhere within the 32-bit wide register through the use of the First Bit Shifted configuration field, which selects the bit index (between 31 and 0) of the first bit shifted.

Examples of supported data alignment and the required First Bit Shifted configuration are illustrated in [Figure 37-2](#) for LSB First configurations and [Figure 37-3](#) for MSB First configurations.

**Figure 37-2. SAI first bit shifted, LSB first**

**Figure 37-3. SAI first bit shifted, MSB first**

### 37.4.5.2 FIFO pointers

When writing to a Transmit Data Register ( $TDR_n$ ), the Write FIFO Pointer (WFP) of the corresponding Transmit FIFO Register ( $TFR_n$ ) increments after each valid write. The SAI supports 8-bit, 16-bit and 32-bit writes to the Transmit Data Register and the FIFO pointer will increment after each individual write. Note that 8-bit writes should only be used when transmitting up to 8-bit data; 16-bit writes should only be used when transmitting up to 16-bit data.

- If the Transmit FIFO is full, then writes to a Transmit Data Register are ignored.
- If the Transmit FIFO is empty, then to avoid a FIFO underrun, the Transmit Data Register must be written at least 3 bit clocks before the start of the next unmasked word. Before enabling the transmitter, the Transmit FIFO should be initialized with data (since after the transmitter is enabled, the transmitter will start a new frame, and if no data is in the FIFO, then the transmitter will immediately give an error).

When reading a Receive Data Register ( $RDR_n$ ), the Read FIFO Pointer (RFP) of the corresponding Receive FIFO Register ( $RFR_n$ ) increments after each valid read. The SAI supports 8-bit, 16-bit and 32-bit reads from the RDR and the FIFO pointer will increment after each individual read. Note that 8-bit reads should only be used when receiving up to 8-bit data; 16-bit reads should only be used when receiving up to 16-bit data.

- If the Receive FIFO is empty, then reads from a Receive Data Register are ignored.
- If the Receive FIFO is full, then to avoid a FIFO overrun, the Receive Data Register must be read at least 3 bit clocks before the end of an unmasked word.

### 37.4.5.3 FIFO packing

FIFO packing supports storing multiple 8-bit or 16-bit data words in one 32-bit FIFO word for the transmitter and/or receiver. While this can be emulated by adjusting the number of bits per word and number of words per frame (for example, one 32-bit word per frame versus two 16-bit words per frame), FIFO packing does not require even multiples of words per frame and fully supports word masking. When FIFO packing is enabled, the FIFO pointers only increment when the full 32-bit FIFO word has been written (transmit) or read (receive) by software, supporting scenarios where different words within each frame are loaded/stored in different areas of memory.

When 16-bit FIFO packing is enabled for transmit, the transmit shift register is loaded at the start of each frame and after every second unmasked transmit word. The first word transmitted is taken from 16-bit word at byte offset \$0 (first bit is selected by  $TCFG5[FBT]$  must be configured within this 16-bit word) and the second word transmitted is taken from the 16-bit word at byte offset \$2 (first bit is selected by  $TCSR5[FBT][3:0]$ ). The transmitter will transmit logic zero until the start of the next word once the 16-bit word has been transmitted.

When 16-bit FIFO packing is enabled for receive, the receive shift register is stored after every second unmasked received word, and at the end of each frame if there is an odd number of unmasked received words in each frame. The first word received is stored in the 16-bit word at byte offset \$0 (first bit is selected by RCFG5[FBT] and must be configured within this 16-bit word) and the second word received is stored in the 16-bit word at byte offset \$2 (first bit is selected by RCSR5[FBT][3:0]). The receiver will ignore received data until the start of the next word once the 16-bit word has been received.

The 8-bit FIFO packing is similar to 16-bit packing except four words are loaded or stored into each 32-bit FIFO word. The first word is loaded/stored in byte offset \$0, second word in byte offset \$1, third word in byte offset \$2 and fourth word in byte offset \$3. The TCFG5[FBT] and/or RCFG5[FBT] must be configured within byte offset \$0.

### 37.4.6 Word mask register

The SAI transmitter and receiver each contain a word mask register, namely TMR and RMR, that can be used to mask any word in the frame. Because the word mask register is double buffered, software can update it before the end of each frame to mask a particular word in the next frame.

The TMR causes the Transmit Data pin to be tri-stated for the length of each selected word and the transmit FIFO is not read for masked words.

The RMR causes the received data for each selected word to be discarded and not written to the receive FIFO.

### 37.4.7 Interrupts and DMA requests

The SAI transmitter and receiver generate separate interrupts and separate DMA requests, but support the same status flags. Asynchronous versions of the transmitter and receiver interrupts are generated to wake up the CPU from stop mode.

#### 37.4.7.1 FIFO request flag

The FIFO request flag is set based on the number of entries in the FIFO and the FIFO watermark configuration.

The transmit FIFO request flag is set when the number of entries in any of the enabled transmit FIFOs is less than or equal to the transmit FIFO watermark configuration and is cleared when the number of entries in each enabled transmit FIFO is greater than the transmit FIFO watermark configuration.

The receive FIFO request flag is set when the number of entries in any of the enabled receive FIFOs is greater than the receive FIFO watermark configuration and is cleared when the number of entries in each enabled receive FIFO is less than or equal to the receive FIFO watermark configuration.

The FIFO request flag can generate an interrupt or a DMA request.

### **37.4.7.2 FIFO warning flag**

The FIFO warning flag is set based on the number of entries in the FIFO.

The transmit warning flag is set when the number of entries in any of the enabled transmit FIFOs is empty and is cleared when the number of entries in each enabled transmit FIFO is not empty.

The receive warning flag is set when the number of entries in any of the enabled receive FIFOs is full and is cleared when the number of entries in each enabled receive FIFO is not full.

The FIFO warning flag can generate an Interrupt or a DMA request.

### **37.4.7.3 FIFO error flag**

The transmit FIFO error flag is set when the any of the enabled transmit FIFOs underflow. After it is set, all enabled transmit channels will transmit zero data before TCSR[FEF] is cleared.

When TCR4[FCONT] is set, the FIFO will continue transmitting data following an underflow without software intervention. To ensure that data is transmitted in the correct order, the transmitter will continue from the same word number in the frame that caused the FIFO to underflow, but only after new data has been written to the transmit FIFO. Software should still clear the TCSR[FEF] flag, but without reinitializing the transmit FIFOs.

RCSR[FEF] is set when the any of the enabled receive FIFOs overflow. After it is set, all enabled receive channels discard received data until RCSR[FEF] is cleared and the next next receive frame starts. All enabled receive FIFOs should be emptied before RCSR[FEF] is cleared.

When RCR4[FCONT] is set, the FIFO will continue receiving data following an overflow without software intervention. To ensure that data is received in the correct order, the receiver will continue from the same word number in the frame that caused the FIFO to overflow, but only after data has been read from the receive FIFO. Software should still clear the RCSR[FEF] flag, but without emptying the receive FIFOs.

The FIFO error flag can generate only an interrupt.

#### **37.4.7.4 Sync error flag**

The sync error flag, TCSR[SEF] or RCSR[SEF], is set when configured for an externally generated frame sync and the external frame sync asserts when the transmitter or receiver is busy with the previous frame. The external frame sync assertion is ignored and the sync error flag is set. When the sync error flag is set, the transmitter or receiver continues checking for frame sync assertion when idle or at the end of each frame.

The sync error flag can generate an interrupt only.

#### **37.4.7.5 Word start flag**

The word start flag is set at the start of the second bit clock for the selected word, as configured by the Word Flag register field.

The word start flag can generate an interrupt only.

### **37.5 Memory map and register definition**

A read or write access to an address from offset 0x100 and above will result in a bus error.

#### **37.5.1 I2S register descriptions**

##### **37.5.1.1 I2S Memory map**

## 37.5.1.4.3 Fields

Field	Function
31 TE	Transmitter Enable Enables/disables the transmitter. When software clears this field, the transmitter remains enabled, and this bit remains set, until the end of the current frame. 0b - Transmitter is disabled. 1b - Transmitter is enabled, or transmitter has been disabled and has not yet reached end of frame.
30 STOPE	Stop Enable Configures transmitter operation in Stop mode. 0b - Transmitter disabled in Stop mode. 1b - Transmitter enabled in Stop mode.
29 DBGE	Debug Enable Enables/disables transmitter operation in Debug mode. The transmit bit clock is not affected by debug mode. 0b - Transmitter is disabled in Debug mode, after completing the current frame. 1b - Transmitter is enabled in Debug mode.
28 BCE	Bit Clock Enable Enables the transmit bit clock, separately from the TE. This field is automatically set whenever TE is set. When software clears this field, the transmit bit clock remains enabled, and this bit remains set, until the end of the current frame. 0b - Transmit bit clock is disabled. 1b - Transmit bit clock is enabled.
27-26 —	Reserved
25 FR	FIFO Reset Empties the FIFO, and sets the FIFO read and write pointers to the same value, which may or may not be zero. Reading this field will always return zero. FIFO pointers should only be reset when the transmitter is disabled or the FIFO error flag is set. 0b - No effect. 1b - FIFO reset.
24	Software Reset

Table continues on the next page...

## Memory map and register definition

Field	Function
SR	When set, resets the internal transmitter logic including the FIFO read and write pointers. Software-visible registers are not affected, except for the status registers. 0b - No effect. 1b - Software reset.
23-21 —	Reserved
20 WSF	Word Start Flag Indicates that the start of the configured word has been detected. Write a logic 1 to this field to clear this flag. 0b - Start of word not detected. 1b - Start of word detected.
19 SEF	Sync Error Flag Indicates that an error in the externally-generated frame sync has been detected. Write a logic 1 to this field to clear this flag. 0b - Sync error not detected. 1b - Frame sync error detected.
18 FEF	FIFO Error Flag Indicates that an enabled transmit FIFO has underrun. Write a logic 1 to this field to clear this flag. 0b - Transmit underrun not detected. 1b - Transmit underrun detected.
17 FWF	FIFO Warning Flag Indicates that an enabled transmit FIFO is empty. 0b - No enabled transmit FIFO is empty. 1b - Enabled transmit FIFO is empty.
16 FRF	FIFO Request Flag Indicates that the number of words in an enabled transmit channel FIFO is less than or equal to the transmit FIFO watermark. 0b - Transmit FIFO watermark has not been reached. 1b - Transmit FIFO watermark has been reached.
15-13 —	Reserved
12 WSIE	Word Start Interrupt Enable Enables/disables word start interrupts. 0b - Disables interrupt. 1b - Enables interrupt.
11 SEIE	Sync Error Interrupt Enable Enables/disables sync error interrupts. 0b - Disables interrupt. 1b - Enables interrupt.
10 FEIE	FIFO Error Interrupt Enable Enables/disables FIFO error interrupts. 0b - Disables the interrupt. 1b - Enables the interrupt.
9 FWIE	FIFO Warning Interrupt Enable Enables/disables FIFO warning interrupts. 0b - Disables the interrupt. 1b - Enables the interrupt.

*Table continues on the next page...*

Field	Function
8 FRIE	FIFO Request Interrupt Enable Enables/disables FIFO request interrupts. 0b - Disables the interrupt. 1b - Enables the interrupt.
7-5 —	Reserved
4-2 —	Reserved
1 FWDE	FIFO Warning DMA Enable Enables/disables DMA requests. 0b - Disables the DMA request. 1b - Enables the DMA request.
0 FRDE	FIFO Request DMA Enable Enables/disables DMA requests. 0b - Disables the DMA request. 1b - Enables the DMA request.

TCR2	10h

#### 37.5.1.6.2 Function

This register must not be altered when TCSR[TE] is set.

#### 37.5.1.6.3 Diagram

#### 37.5.1.6.4 Fields

Field	Function
31-30 SYNC	Synchronous Mode Configures between asynchronous and synchronous modes of operation. When configured for a synchronous mode of operation, the receiver or other SAI peripheral must be configured for asynchronous operation.

Table continues on the next page...

Field	Function
	00b - Asynchronous mode. 01b - Synchronous with receiver. 10b - Synchronous with another SAI transmitter. 11b - Synchronous with another SAI receiver.
29 BCS	<b>Bit Clock Swap</b> This field swaps the bit clock used by the transmitter. When the transmitter is configured in asynchronous mode and this bit is set, the transmitter is clocked by the receiver bit clock (RX_BCLK). This allows the transmitter and receiver to share the same bit clock, but the transmitter continues to use the transmit frame sync (TX_SYNC). When the transmitter is configured in synchronous mode, the transmitter BCS field and receiver BCS field must be set to the same value. When both are set, the transmitter and receiver are both clocked by the transmitter bit clock (TX_BCLK) but use the receiver frame sync (RX_SYNC). This field has no effect when synchronous to another SAI peripheral. 0b - Use the normal bit clock source. 1b - Swap the bit clock source.
28 BCI	<b>Bit Clock Input</b> When this field is set and using an internally generated bit clock in either synchronous or asynchronous mode, the bit clock actually used by the transmitter is delayed by the pad output delay (the transmitter is clocked by the pad input as if the clock was externally generated). This has the effect of decreasing the data input setup time, but increasing the data output valid time. The slave mode timing from the datasheet should be used for the transmitter when this bit is set. In synchronous mode, this bit allows the transmitter to use the slave mode timing from the datasheet, while the receiver uses the master mode timing. This field has no effect when configured for an externally generated bit clock or when synchronous to another SAI peripheral . 0b - No effect. 1b - Internal logic is clocked as if bit clock was externally generated.
27-26 MSEL	<b>MCLK Select</b> Selects the audio Master Clock option used to generate an internally generated bit clock. This field has no effect when configured for an externally generated bit clock. <b>NOTE:</b> Depending on the device, some Master Clock options might not be available. See the chip-specific information for the meaning of each option. 00b - Bus Clock selected. 01b - Master Clock (MCLK) 1 option selected. 10b - Master Clock (MCLK) 2 option selected. 11b - Master Clock (MCLK) 3 option selected.
25 BCP	<b>Bit Clock Polarity</b> Configures the polarity of the bit clock. 0b - Bit clock is active high with drive outputs on rising edge and sample inputs on falling edge. 1b - Bit clock is active low with drive outputs on falling edge and sample inputs on rising edge.
24 BCD	<b>Bit Clock Direction</b> Configures the direction of the bit clock. 0b - Bit clock is generated externally in Slave mode. 1b - Bit clock is generated internally in Master mode.
23-8 —	Reserved
7-0 DIV	<b>Bit Clock Divide</b> Divides down the audio master clock to generate the bit clock when configured for an internal bit clock. The division value is $(DIV + 1) * 2$ .

## Memory map and register definition

Field	Function
28 FCONT	FIFO Continue on Error Configures when the SAI will continue transmitting after a FIFO error has been detected. 0b - On FIFO error, the SAI will continue from the start of the next frame after the FIFO error flag has been cleared. 1b - On FIFO error, the SAI will continue from the same word that caused the FIFO error to set after the FIFO warning flag has been cleared.
27-26 —	Reserved
25-24 FPACK	FIFO Packing Mode Enables packing of 8-bit data or 16-bit data into each 32-bit FIFO word. If the word size is greater than 8-bit or 16-bit then only the first 8-bit or 16-bits are loaded from the FIFO. The first word in each frame always starts with a new 32-bit FIFO word and the first bit shifted must be configured within the first packed word. When FIFO packing is enabled, the FIFO write pointer will only increment when the full 32-bit FIFO word has been written by software.  00b - FIFO packing is disabled 01b - Reserved 10b - 8-bit FIFO packing is enabled 11b - 16-bit FIFO packing is enabled
23-21 —	Reserved
20-16 FRSZ	Frame size Configures the number of words in each frame. The value written must be one less than the number of words in the frame. For example, write 0 for one word per frame. The maximum supported frame size is 32 words.
15-13 —	Reserved
12-8 SYWD	Sync Width Configures the length of the frame sync in number of bit clocks. The value written must be one less than the number of bit clocks. For example, write 0 for the frame sync to assert for one bit clock only. The sync width cannot be configured longer than the first word of the frame.
7-6 —	Reserved
5 CHMOD	Channel Mode Configures if transmit data pins are configured for TDM mode or Output mode. 0b - TDM mode, transmit data pins are tri-stated when slots are masked or channels are disabled. 1b - Output mode, transmit data pins are never tri-stated and will output zero when slots are masked or channels are disabled.
4 MF	MSB First Configures whether the LSB or the MSB is transmitted first. 0b - LSB is transmitted first. 1b - MSB is transmitted first.
3 FSE	Frame Sync Early 0b - Frame sync asserts with the first bit of the frame. 1b - Frame sync asserts one bit before the first bit of the frame.
2 ONDEM	On Demand Mode When set, and the frame sync is generated internally, a frame sync is only generated when the FIFO warning flag is clear.

*Table continues on the next page...*

Field	Function
	0b - Internal frame sync is generated continuously. 1b - Internal frame sync is generated when the FIFO warning flag is clear.
1 FSP	Frame Sync Polarity Configures the polarity of the frame sync. 0b - Frame sync is active high. 1b - Frame sync is active low.
0 FSD	Frame Sync Direction Configures the direction of the frame sync. 0b - Frame sync is generated externally in Slave mode. 1b - Frame sync is generated internally in Master mode.

## Memory map and register definition

Field	Function
—	
30-22 —	Reserved
21-16 WFP	Write FIFO Pointer FIFO write pointer for transmit data channel.
15-6 —	Reserved
5-0 RFP	Read FIFO Pointer FIFO read pointer for transmit data channel.

### 37.5.1.12 SAI Transmit Mask Register (TMR)

#### 37.5.1.12.1 Offset

Register	Offset
TMR	60h

#### 37.5.1.12.2 Function

This register is double-buffered and updates:

1. When TCSR[TE] is first set
2. At the end of each frame.

This allows the masked words in each frame to change from frame to frame.

#### 37.5.1.12.3 Diagram

### 37.5.1.12.4 Fields

Field	Function
31-0 TWM	Transmit Word Mask Configures whether the transmit word is masked (transmit data pins are tri-stated or drive zero and transmit data not read from FIFO) for the corresponding word in the frame. 0000000000000000000000000000000b - Word N is enabled. 00000000000000000000000000000001b - Word N is masked. The transmit data pins are tri-stated or drive zero when masked.

### 37.5.1.13 SAI Receive Control Register (RCSR)

#### 37.5.1.13.1 Offset

Register	Offset
RCSR	88h

#### 37.5.1.13.2 Diagram

#### 37.5.1.13.3 Fields

Field	Function
31 RE	Receiver Enable Enables/disables the receiver. When software clears this field, the receiver remains enabled, and this bit remains set, until the end of the current frame. 0b - Receiver is disabled.

Table continues on the next page...

## Memory map and register definition

Field	Function
	1b - Receiver is enabled, or receiver has been disabled and has not yet reached end of frame.
30 STOPE	Stop Enable Configures receiver operation in Stop mode. 0b - Receiver disabled in Stop mode. 1b - Receiver enabled in Stop mode.
29 DBGE	Debug Enable Enables/disables receiver operation in Debug mode. The receive bit clock is not affected by Debug mode. 0b - Receiver is disabled in Debug mode, after completing the current frame. 1b - Receiver is enabled in Debug mode.
28 BCE	Bit Clock Enable Enables the receive bit clock, separately from RE. This field is automatically set whenever RE is set. When software clears this field, the receive bit clock remains enabled, and this field remains set, until the end of the current frame. 0b - Receive bit clock is disabled. 1b - Receive bit clock is enabled.
27-26 —	Reserved
25 FR	FIFO Reset Empties the FIFO, and sets the FIFO read and write pointers to the same value, which may or may not be zero. Reading this field will always return zero. FIFO pointers should only be reset when the receiver is disabled or the FIFO error flag is set. 0b - No effect. 1b - FIFO reset.
24 SR	Software Reset Resets the internal receiver logic including the FIFO pointers. Software-visible registers are not affected, except for the status registers. 0b - No effect. 1b - Software reset.
23-21 —	Reserved
20 WSF	Word Start Flag Indicates that the start of the configured word has been detected. Write a logic 1 to this field to clear this flag. 0b - Start of word not detected. 1b - Start of word detected.
19 SEF	Sync Error Flag Indicates that an error in the externally-generated frame sync has been detected. Write a logic 1 to this field to clear this flag. 0b - Sync error not detected. 1b - Frame sync error detected.
18 FEF	FIFO Error Flag Indicates that an enabled receive FIFO has overflowed. Write a logic 1 to this field to clear this flag. 0b - Receive overflow not detected. 1b - Receive overflow detected.
17 FWF	FIFO Warning Flag Indicates that an enabled receive FIFO is full. 0b - No enabled receive FIFO is full.

*Table continues on the next page...*

Field	Function
	1b - Enabled receive FIFO is full.
16 FRF	FIFO Request Flag Indicates that the number of words in an enabled receive channel FIFO is greater than the receive FIFO watermark. 0b - Receive FIFO watermark not reached. 1b - Receive FIFO watermark has been reached.
15-13 —	Reserved
12 WSIE	Word Start Interrupt Enable Enables/disables word start interrupts. 0b - Disables interrupt. 1b - Enables interrupt.
11 SEIE	Sync Error Interrupt Enable Enables/disables sync error interrupts. 0b - Disables interrupt. 1b - Enables interrupt.
10 FEIE	FIFO Error Interrupt Enable Enables/disables FIFO error interrupts. 0b - Disables the interrupt. 1b - Enables the interrupt.
9 FWIE	FIFO Warning Interrupt Enable Enables/disables FIFO warning interrupts. 0b - Disables the interrupt. 1b - Enables the interrupt.
8 FRIE	FIFO Request Interrupt Enable Enables/disables FIFO request interrupts. 0b - Disables the interrupt. 1b - Enables the interrupt.
7-5 —	Reserved
4-2 —	Reserved
1 FWDE	FIFO Warning DMA Enable Enables/disables DMA requests. 0b - Disables the DMA request. 1b - Enables the DMA request.
0 FRDE	FIFO Request DMA Enable Enables/disables DMA requests. 0b - Disables the DMA request. 1b - Enables the DMA request.

### 37.5.1.15.4 Fields

Field	Function
31-30 SYNC	<p>Synchronous Mode</p> <p>Configures between asynchronous and synchronous modes of operation. When configured for a synchronous mode of operation, the transmitter or other SAI peripheral must be configured for asynchronous operation.</p> <p>00b - Asynchronous mode. 01b - Synchronous with transmitter. 10b - Synchronous with another SAI receiver. 11b - Synchronous with another SAI transmitter.</p>
29 BCS	<p>Bit Clock Swap</p> <p>This field swaps the bit clock used by the receiver. When the receiver is configured in asynchronous mode and this bit is set, the receiver is clocked by the transmitter bit clock (TX_BCLK). This allows the transmitter and receiver to share the same bit clock, but the receiver continues to use the receiver frame sync (RX_SYNC).</p> <p>When the receiver is configured in synchronous mode, the transmitter BCS field and receiver BCS field must be set to the same value. When both are set, the transmitter and receiver are both clocked by the receiver bit clock (RX_BCLK) but use the transmitter frame sync (TX_SYNC).</p> <p>This field has no effect when synchronous to another SAI peripheral.</p> <p>0b - Use the normal bit clock source. 1b - Swap the bit clock source.</p>
28 BCI	<p>Bit Clock Input</p> <p>When this field is set and using an internally generated bit clock in either synchronous or asynchronous mode, the bit clock actually used by the receiver is delayed by the pad output delay (the receiver is clocked by the pad input as if the clock was externally generated). This has the effect of decreasing the data input setup time, but increasing the data output valid time.</p> <p>The slave mode timing from the datasheet should be used for the receiver when this bit is set. In synchronous mode, this bit allows the receiver to use the slave mode timing from the datasheet, while the transmitter uses the master mode timing. This field has no effect when configured for an externally generated bit clock or when synchronous to another SAI peripheral.</p> <p>0b - No effect. 1b - Internal logic is clocked as if bit clock was externally generated.</p>
27-26	MCLK Select

Table continues on the next page...

## Memory map and register definition

Field	Function
MSEL	Selects the audio Master Clock option used to generate an internally generated bit clock. This field has no effect when configured for an externally generated bit clock.  <b>NOTE:</b> Depending on the device, some Master Clock options might not be available. See the chip-specific information for the availability and chip-specific meaning of each option. 00b - Bus Clock selected. 01b - Master Clock (MCLK) 1 option selected. 10b - Master Clock (MCLK) 2 option selected. 11b - Master Clock (MCLK) 3 option selected.
25 BCP	Bit Clock Polarity Configures the polarity of the bit clock. 0b - Bit Clock is active high with drive outputs on rising edge and sample inputs on falling edge. 1b - Bit Clock is active low with drive outputs on falling edge and sample inputs on rising edge.
24 BCD	Bit Clock Direction Configures the direction of the bit clock. 0b - Bit clock is generated externally in Slave mode. 1b - Bit clock is generated internally in Master mode.
23-8 —	Reserved
7-0 DIV	Bit Clock Divide Divides down the audio master clock to generate the bit clock when configured for an internal bit clock. The division value is $(DIV + 1) * 2$ .

Field	Function
31-25 —	Reserved
24 —	Reserved
23-17 —	Reserved
16 RCE	<p>Receive Channel Enable</p> <p>Enables the corresponding data channel for receive operation. Changing this field will take effect immediately for generating the FIFO request and warning flags, but at the end of each frame for receive operation.</p> <p>The width of RCE field = the number of receive channels (call it N). For example, if RCE field is 2 bits wide, then bit position 16 refers to receive channel 1 and bit position 17 refers to receive channel 2. Setting bit 16 enables receive channel 1, and setting bit 17 enables receive channel 2. Setting bit N will enable receive channel N.</p> <p>0b - Receive data channel N is disabled. 1b - Receive data channel N is enabled.</p>
15-5 —	Reserved
4-0 WDFL	<p>Word Flag Configuration</p> <p>Configures which word the start of word flag is set. The value written should be one less than the word number (for example, write zero to configure for the first word in the frame). When configured to a value greater than the Frame Size field, then the start of word flag is never set.</p>

## 37.5.1.17 SAI Receive Configuration 4 Register (RCR4)

### 37.5.1.17.1 Offset

Register	Offset
RCR4	98h

### 37.5.1.17.2 Function

This register must not be altered when RCSR[RE] is set.

### 37.5.1.17.3 Diagram

### 37.5.1.17.4 Fields

Field	Function
31-29 —	Reserved
28 FCONT	FIFO Continue on Error Configures when the SAI will continue receiving after a FIFO error has been detected. 0b - On FIFO error, the SAI will continue from the start of the next frame after the FIFO error flag has been cleared. 1b - On FIFO error, the SAI will continue from the same word that caused the FIFO error to set after the FIFO warning flag has been cleared.
27-26 —	Reserved
25-24 FPACK	FIFO Packing Mode Enables packing of 8-bit data or 16-bit data into each 32-bit FIFO word. If the word size is greater than 8-bit or 16-bit then only the first 8-bit or 16-bits are stored to the FIFO. The first word in each frame always starts with a new 32-bit FIFO word and the first bit shifted must be configured within the first packed word. When FIFO packing is enabled, the FIFO read pointer will only increment when the full 32-bit FIFO word has been read by software.  00b - FIFO packing is disabled 01b - Reserved. 10b - 8-bit FIFO packing is enabled 11b - 16-bit FIFO packing is enabled
23-21 —	Reserved
20-16 FRSZ	Frame Size Configures the number of words in each frame. The value written must be one less than the number of words in the frame. For example, write 0 for one word per frame. The maximum supported frame size is 32 words.
15-13 —	Reserved

Table continues on the next page...

Field	Function
12-8 SYWD	Sync Width Configures the length of the frame sync in number of bit clocks. The value written must be one less than the number of bit clocks. For example, write 0 for the frame sync to assert for one bit clock only. The sync width cannot be configured longer than the first word of the frame.
7-6 —	Reserved
5 —	Reserved. Software should only write zero to this bit.
4 MF	MSB First Configures whether the LSB or the MSB is received first. 0b - LSB is received first. 1b - MSB is received first.
3 FSE	Frame Sync Early 0b - Frame sync asserts with the first bit of the frame. 1b - Frame sync asserts one bit before the first bit of the frame.
2 ONDEM	On Demand Mode When set, and the frame sync is generated internally, a frame sync is only generated when the FIFO warning flag is clear. 0b - Internal frame sync is generated continuously. 1b - Internal frame sync is generated when the FIFO warning flag is clear.
1 FSP	Frame Sync Polarity Configures the polarity of the frame sync. 0b - Frame sync is active high. 1b - Frame sync is active low.
0 FSD	Frame Sync Direction Configures the direction of the frame sync. 0b - Frame Sync is generated externally in Slave mode. 1b - Frame Sync is generated internally in Master mode.

5-0 RFP	Read FIFO Pointer FIFO read pointer for receive data channel.

## 37.5.1.21 SAI Receive Mask Register (RMR)

### 37.5.1.21.1 Offset

Register	Offset
RMR	E0h

### 37.5.1.21.2 Function

This register is double-buffered and updates:

1. When RCSR[RE] is first set
2. At the end of each frame

This allows the masked words in each frame to change from frame to frame.

### 37.5.1.21.3 Diagram

### 37.5.1.21.4 Fields

Field	Function
31-0 RWM	Receive Word Mask Configures whether the receive word is masked (received data ignored and not written to receive FIFO) for the corresponding word in the frame. 00000000000000000000000000000000b - Word N is enabled. 00000000000000000000000000000001b - Word N is masked.

# Chapter 38

## Medium Quality Sound (MQS)

### 38.1 Chip-specific MQS information

Table 38-1. Reference links to related information

Topic	Related module or subsystem	Reference
System memory map	-	<a href="#">System Memory Map</a>
Clocking	CCM	<a href="#">Clock Management</a> <a href="#">Clock Control Module (CCM)</a>
Audio Subsystem	Audio Subsystem	<a href="#">Audio Subsystem Overview</a>
Power management	PMU	<a href="#">Power Management</a> <a href="#">Power Management Unit</a>
Signal multiplexing	IOMUX	<a href="#">External Signals and Pin Multiplexing</a> <a href="#">IOMUX</a>
Interrupts, DMA Events and XBAR Assignments	-	<a href="#">Interrupts, DMA Events and XBAR Assignments</a>

### 38.2 Overview

Medium quality sound (MQS) is used to generate medium quality audio via a standard GPIO in the pinmux, allowing the user to connect stereo speakers or headphones to a power amplifier without an additional DAC chip.

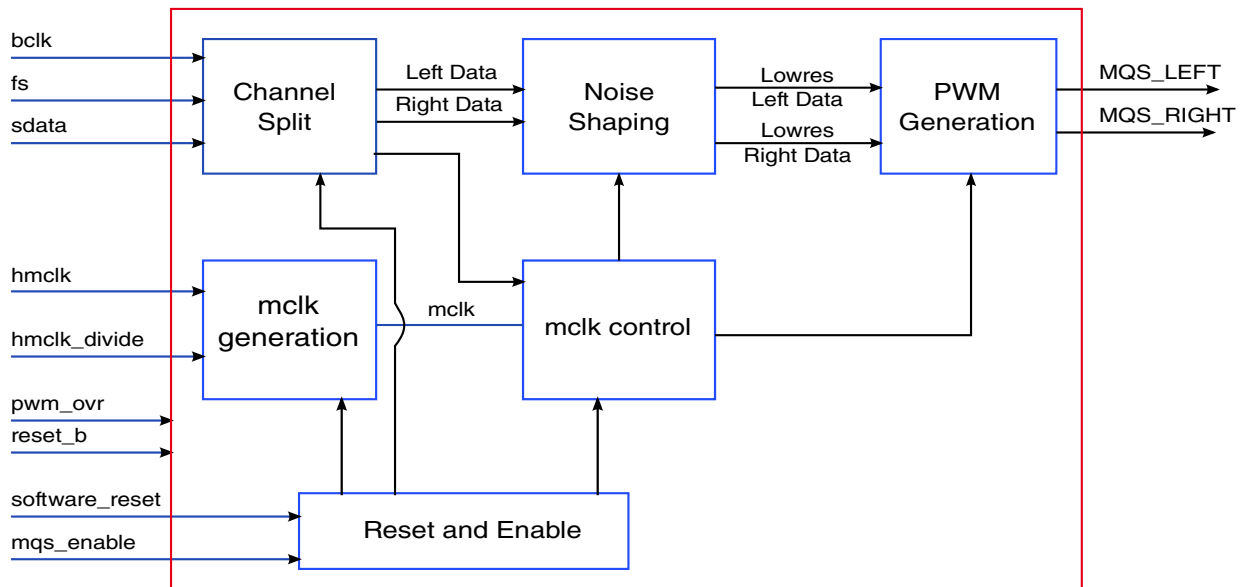

MQS accepts the following inputs:

- 2-channel, LSB-valid 16-bit, MSB shift-out first serial data (sdata)
- Frame sync asserting with the first bit of the frame (fs)
- Bit clock used to shift data out on the positive clock edge (bclk)

The 44 kHz or 48 kHz input signals from SAI3 are in left\_justified format. MQS provides the SNR target as no more than 20 dB for the signals below 10 kHz. The signals above 10 kHz will have worse THD+N values.

MQS provides only simple audio reproduction. No internal pop, click or distortion artifact reduction methods are provided.

### 38.2.1 Block Diagram

**Figure 38-1. Block Diagram**

MQS has the following sub-modules:

1. Channel Split: Splits the I2S signals into separate left channel and right channel audio data.
2. Noise Shaping: Uses the sigma-delta algorithm to generate low-resolution, very high sampling audio, while the audio sampling rate is increased.
3. PWM generation: Generates the bit stream to the GPIO, which is then used to drive the amplifier and then to drive the external speakers or headphones.
4. mclk generation: Used to generate the master clock (mclk). The frequency of mclk is determined by the final bit duration of PWM generation module.
5. mclk control: Used as a metronome to co-ordinate the different functional blocks working synchronously.
6. Reset and Enable: Used to generate the reset and enable logic to different clock domains.

## 38.3 External Signals

The following table describes the external signals of MQS:

**Table 38-2. MQS External Signals**

Signal	Description	Pad	Mode	Direction
MQS_RIGHT	Right signal output	GPIO_AD_B0_04	ALT1	O
		GPIO_B0_00	ALT2	
		GPIO_EMC_13	ALT3	
MQS_LEFT	Left signal output	GPIO_EMC_14	ALT3	O
		GPIO_B0_01	ALT2	
		GPIO_AD_B0_05	ALT1	

## 38.4 Interface Signals

MQS module has the following interface signals.

Signal Name	In/Out	BitWidth	Description	Comments
reset_b	In	1	asynchronous reset	
software_reset	In	1	Software reset	From GPR
mqs_enable	In	1	module enable	From GPR
pwm_ovr	In	1	PWM oversampling ratio1—64, 0--32	From GPR
hmclk	In	1	Maximum bit clock, used to generate the mclk, divider ratio is controlled by mqs_hmclk_divide	Max 66.5MHzTypical 24.576MHz
hmclk_divide	In	8	Divider ration control for mclk from hmclk	From GPR
bclk	In	1	bit clock from I2S signal	
fs	In	1	frame sync clock from I2S signal	
sdata	In	1	serial audio data from I2S signal	

## 38.5 Programming Considerations

MQS has no internal programmable registers. But it does have some programmability from IOMUXC\_GPR2.

Register Bits	Name	Description
IOMUXC_GPR2[26]	MQS_OVERSAMPLE	Used to control the PWM oversampling rate compared with mclk. 1—64, 0—32.
IOMUXC_GPR2[25]	MQS_EN	MQS enable. 1—Enable MQS, 0—Disable MQS
IOMUXC_GPR2[24]	MQS_SW_RST	MQS software reset. 1—Enable software reset for MQS 0—Exit software reset for MQS
IOMUXC_GPR2[23:16]	MQS_CLK_DIV[7:0]	Divider ration control for mclk from hmclk. 0—mclk frequency = hmclk frequency; 1—mclk frequency = 1/2*hmclk frequency; 2—mclk frequency = 1/3*hmclk frequency; ...; n—mclk frequency = 1/(n+1)*hmclk frequency

### 38.5.1 Usage Model

Due to the different devices connected to MQS, and different high frequency behaviors of the connected analog circuits, the user needs choose the appropriate MQS\_CLK\_DIV and MQS\_OVERSAMPLE values for the best audible effects.

# Chapter 39

## Sony/Philips Digital Interface (SPDIF)

### 39.1 Chip-specific SPDIF information

Table 39-1. Reference links to related information

Interrupts, DMA Events and XBAR Assignments	-	<a href="#">Interrupts, DMA Events and XBAR Assignments</a>

### 39.2 Overview

The Sony/Philips Digital Interface (SPDIF) audio block is a stereo transceiver that allows the processor to receive and transmit digital audio.

The SPDIF transceiver allows the handling of both SPDIF channel status (CS) and User (U) data and includes a frequency measurement block that allows the precise measurement of an incoming sampling frequency.

A recovered clock is provided to drive both internal components in the system, such as SAI ports, and external components, such as A/Ds or D/As, with clocking control provided via related registers.

## Overview

As the SPDIF internal data width is 24-bit, the eight most-significant bits of all registers return zeros.

The figure below shows a block diagram of the SPDIF transceiver data paths (receiver and transmitter) and its interface.

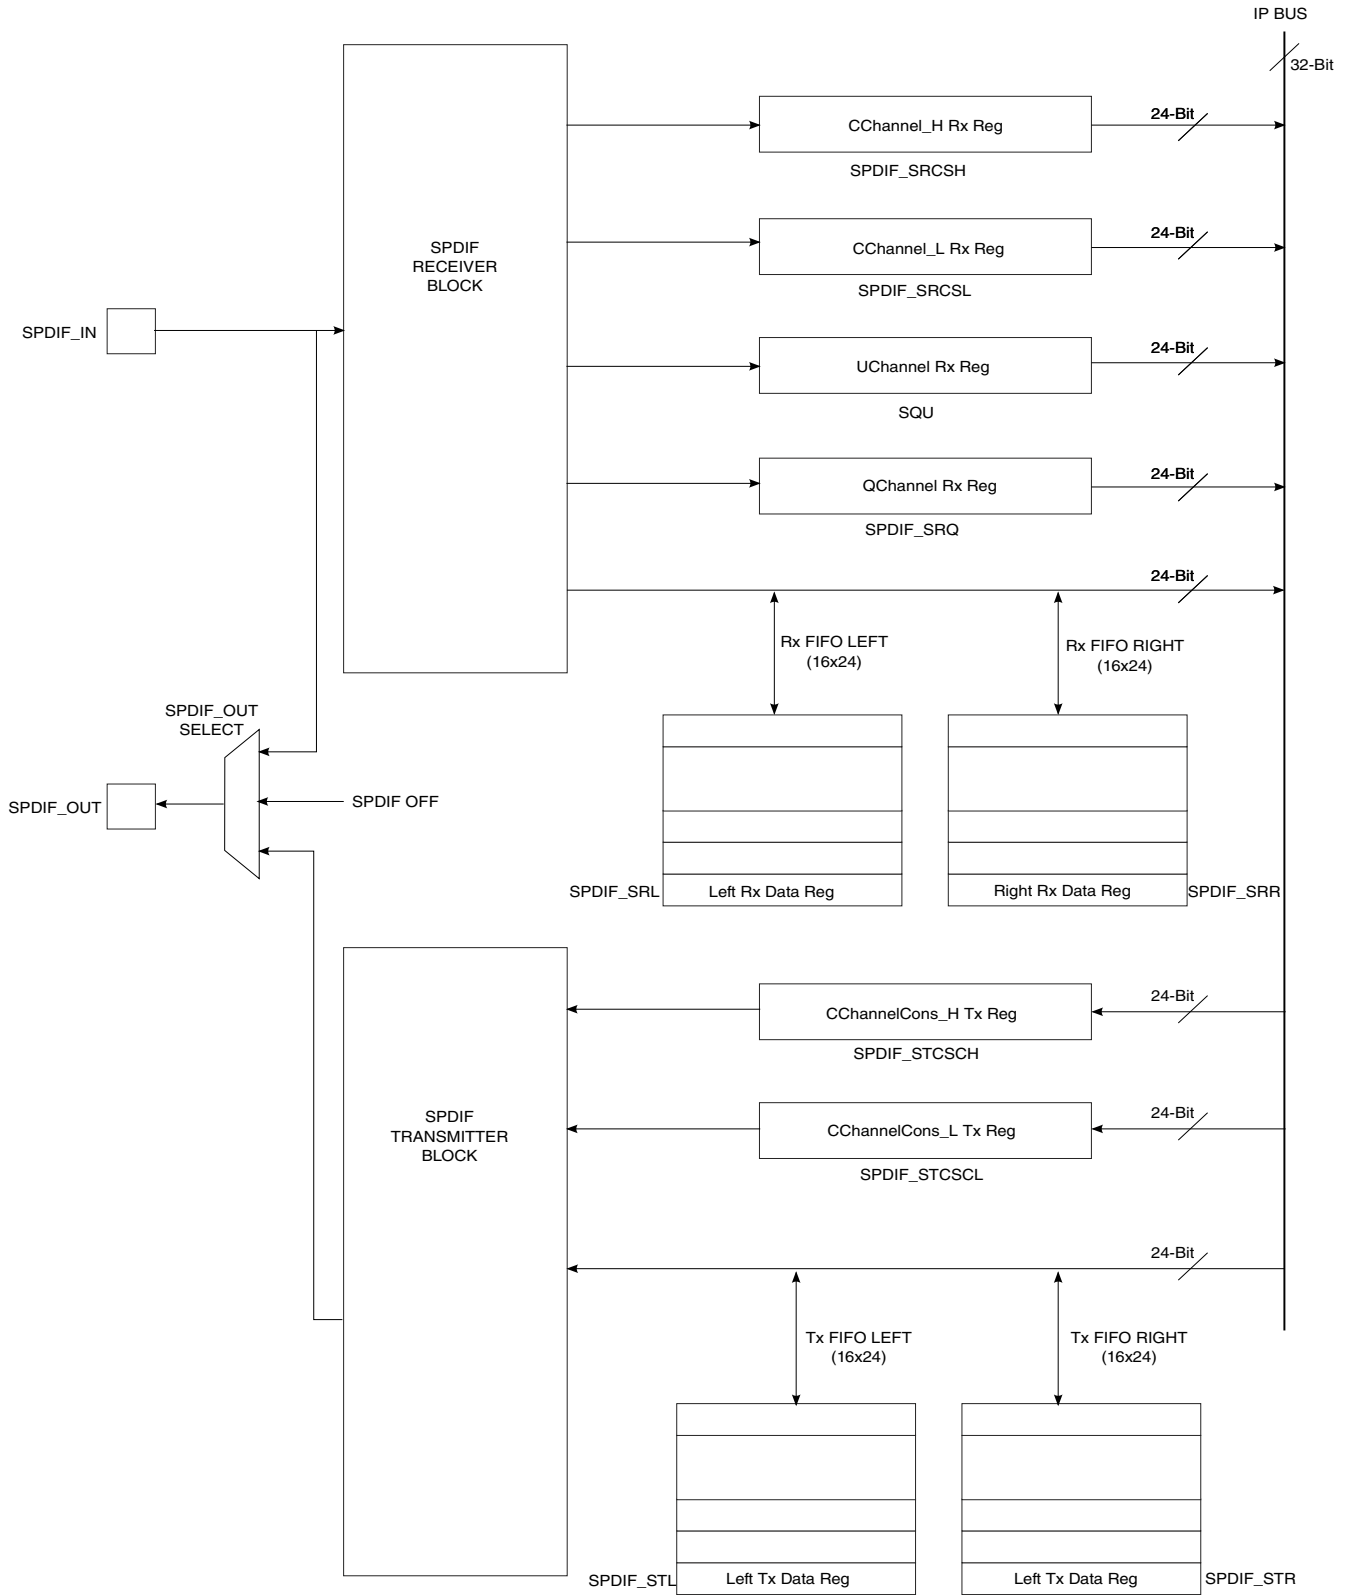

Figure 39-1. SPDIF Transceiver Data Interface Block Diagram

## 39.3 External Signals

The following table describes the external signals of SPDIF:

**Table 39-2. SPDIF External Signals**

Signal	Description	Pad	Mode	Direction
SPDIF_OUT	Output line signal	GPIO_EMC_15	ALT3	O
		GPIO_AD_B1_05	ALT3	
		GPIO_AD_B1_02	ALT3	
SPDIF_IN	Input line	GPIO_EMC_16	ALT3	I
		GPIO_AD_B1_03	ALT3	
SPDIF_SR_CLK	SR clock signal	GPIO_AD_B1_04	ALT3	O
SPDIF_LOCK	Lock signal	GPIO_AD_B1_06	ALT3	O
SPDIF_EXT_CLK	External clock signal	GPIO_AD_B1_07	ALT3	I

## 39.4 Clocks

The table found here describes the clock sources for SPDIF.

Please see clock control block for clock setting, configuration and gating information.

**Table 39-3. SPDIF Clocks**

Clock name	Clock Root	Description
gclkw_t0	ipg_clk_root	Global clock
ipg_clk_s	ipg_clk_root	Peripheral access clock
tx_clk	spdif0_clk_root	Module Tx clock

## 39.5 Functional Description

The SPDIF is composed of two parts: SPDIF Receiver and SPDIF Transmitter.

The SPDIF receiver extracts the audio data from each SPDIF frame and places the data in the SPDIF Rx left and right FIFOs. The Channel Status and User Bits are also extracted from each frame and placed in the corresponding registers. The SPDIF receiver also provides a bypass option for direct transfer of the SPDIF input signal to the SPDIF transmitter.

For the SPDIF transmitter, the audio data is provided by the processor via the SPDIFTxLeft and SPDIFTxRight registers. The Channel Status bits are also provided via the corresponding registers. The SPDIF transmitter generates a SPDIF output bitstream in the biphas mark format (IEC60958), which consists of audio data, channel status and user bits.

In the SPDIF transmitter, the IEC60958 biphas bit stream is generated on both edges of the SPDIF Transmit clock. The SPDIF Transmit clock is generated by the SPDIF internal clock generate block and the sources are from outside of the SPDIF block. For the SPDIF receiver, it can recover the SPDIF Rx clock. [Figure 1](#) shows the clock structure of the SPDIF transceiver.

**Figure 39-2. SPDIF Transceiver Clock Diagram**

### 39.5.1 SPDIF Receiver

The SPDIF receiver extracts the audio data from each SPDIF frame and places the data in Rx left and right FIFOs.

The Tx left and right FIFOs are 16-deep and 24-bit-wide (equal to the audio data width). The Channel Status and User Bits are also extracted from each frame and placed in corresponding registers. The SPDIF receiver also provides a bypass option for direct transfer of the SPDIF input signal to the SPDIF transmitter.

The SPDIF receiver handles the main data audio stream and recovers the bit clock from the SPDIF input signal. The sample rate can be determined from the frequency measuring block. Additionally, the receiver supports the SPDIF C and U channels. The SPDIF C and U channel data is interfaced directly to memory-mapped registers.

All the data registers are controlled by the Interrupt Control Block and transferred to the memory-mapped IP bus.

The following functions are performed by the SPDIF receiver:

- Audio Data Reception see [Audio Data Reception](#)
- Channel Status bits Reception see [Channel Status Reception](#)
- U Channel bits Reception see [User Bit Reception](#)
- Validity Flag Reception see [Validity Flag Reception](#)
- SPDIF Receiver Exception support see [SPDIF Receiver](#)
- SPDIF Lock Detection

### 39.5.1.1 Audio Data Reception

The SPDIF Receiver block extracts the audio data from the IEC60958 stream, and outputs this via Rx left and right FIFOs to the memory-mapped registers SPDIFRxLeft and SPDIFRxRight.

Data from the SPDIF receiver is buffered in receive FIFO, and can be read by the processor from the memory-mapped registers.

- **SPDIF receiver data registers - Behavior on overrun, underrun**

The SPDIF Data Receive registers (SPDIFRxLeft and SPDIFRxRight) have individual FIFOs for left and right channel. As a result, there is always the possibility that left and right FIFOs may go out of sync due to FIFO underruns and FIFO overruns that affect only one part (left or right) of any FIFOs. To prevent this from happening, hardware has been added to the device. Two mechanisms to prevent mismatch between the FIFOs are available.

If a SPDIF Data Rx FIFO overrun occurs on e.g. the right half of the FIFO, the sample that caused the overrun is not written to the right half (due to overrun). Special hardware will make sure the next sample is not written to the left half of the FIFO. If the overrun occurs on the left half of the FIFO, the next sample is not written to the right half of the FIFO.

- **SPDIF receiver data registers - Automatic resynchronization of FIFOs**

An automatic FIFO resynchronization feature is available. It can be enabled and disabled separately for every FIFO. If it is enabled, the hardware will check to see if the left and right FIFOs are in sync. If that is not the case, it will set the filling pointer of the right FIFO to be equal to the filling pointer of the left FIFO.

**Figure 39-3. FIFO Auto-resync Controller State Machine**

The operation is explained from the state diagram shown above. Every FIFO auto-resync controller has a state machine with 3 states: Off, StandBy and On. In the On state, the filling of the left FIFO is compared with the filling of right, and if they are not equal, right is made equal to left, and an interrupt is generated.

The controller will stay in Off state when the feature is disabled. When not disabled, the state machine will go to Off state on any processor read or write to the FIFO. It will go from On or Off to Standby on any left sample read from SPDIF Tx FIFOs, or on any left sample write to SPDIF Rx FIFOs. The controller will go from Standby to On on any right

sample read from SPDIF Tx FIFO, or on any right sample write to SPDIF Rx FIFO. There is a control bit in the SPDIFConfig register to enable/disable the feature for the SPDIF Rx FIFO and SPDIF Tx FIFO.

### **39.5.1.1.1 Application Note**

The automatic FIFO resynchronization can be switched on, and will avoid all mismatches between left and right FIFOs, if the software obeys the following rules: 1. When the left data is read or written to the left FIFO, in the same place of the program, data must be read or written to the right FIFO. Maximum time difference between left and right is 1/2 sample clock. (E.g. if sample frequency is 44 KHz, approximately 10 micro-seconds. For 88 KHz, approximately 5 micro-seconds.) 2. Write/read data to FIFO s at least 2 samples at the time. If there is a mismatch Left-Right, the resync logic may go on only 1 sample clock after last data is read/written to the FIFO. Also acceptable is polling the FIFO, if at least part of the time 2 samples will be read/written to it.

- **SPDIF receiver - Additional features**

There are three exceptions associated with the SPDIF Receivers FIFOs

- full
- under/overrun
- resync

When the "full" condition is set for processor data input registers, the processor should read data from the FIFO, before overrun occurs. When "full" is set, and the FIFO contains e.g. 6 samples, it is acceptable for the software to read first 6 samples from the LEFT address, followed by 6 samples from the RIGHT address, or 6 samples from the RIGHT address, followed by 6 samples from the LEFT address, or 1 sample LEFT, followed by 1 sample RIGHT repeated 6 times. There is no order specified.

The implementation for SPDIF Rx is a double FIFO, one for left and one for right. "full" is set when both FIFOs are full. "underrun, overrun" are set when one of the FIFOs do underrun or do overrun. The resync interrupt means hardware took special action to resynchronize left and right FIFOs.

The FIFO level at which the "full" interrupt is generated, is programmable via the Full Select field in the SPDIFConfigReg register.

#### **Rx FIFO on and Rx FIFO reset.**

Two additional control fields of the SPDIF Rx FIFO are the on/off select and FIFO reset fields.

If on/off select is set to off, all-zero will be read from the FIFO, irrespective of the data received over the SPDIF interface.

If FIFO reset is set, the FIFO is blocked at "1 sample in FIFO". In this, the full interrupt will be on if FullSelect is set to "00". If FullSelect is set to any other value, interrupt will be off. The other interrupts are always off.

### 39.5.1.2 Channel Status Reception

A total of 48 channel status bits are received in two registers. No interpretation is performed by the SPDIF receiver block.

Channel Status Bits are ordered first bit left. CS-channel MSB bit "0" is located in bit position 23 in the memory-mapped register SPDIFRxChannel\_h. CS-channel bit "23" is considered the LSB bit 0 in the register. C-channel bit 24 to 47 is seen as [23:0] bits of register SPDIFRxChannel\_l.

#### 39.5.1.2.1 Channel Status Interrupt

When the value of a new SPDIF "CS" channel status frame is loaded in the register, an interrupt is generated. The interrupt is cleared when the processor writes the corresponding bit in the InterruptStat register.

### 39.5.1.3 User Bit Reception

There are two modes for U Channel reception, CD and non-CD. As is decided by USyncMode (bit 1 of CDText\_Control register).

- **Behavior of U Channel receive interface on incoming CD U Channel Sub-code in SPDIF receiver.**

This mode is selected if UsyncMode, bit 1 in register CD Text control is set "1".

The CD sub-code stream embedded into the SPDIF U channel consists of a sequence of packets. Every packet is made up 98 "symbols". The first two symbols of every packet are "sync symbols", the other 96 symbols are "data symbols".

Any sequence found in the SPDIF U channel stream starting with a leading one, followed by 7 information bits, is recognized as a "data symbol". Subsequent data symbols are separated by "pauses". During the "pause", "zero bits" are seen on the SPDIF U channel.

Data symbols are coming in MSB first. The MSB is the leading one.

When a "long pause" is seen between 2 subsequent "data symbols", the SPDIF receiver will assume the reception of one or more "sync symbols". Table below gives details.

**Table 39-4. Sync Control Bits**

Number of U Channel zero bits	Corresponding number of sync symbols
0-1	Unpredictable, not allowed
2-10	0
11-22	1
23-34	2
35-46	3
>45	Unpredictable, not allowed

The recognition of the number of sync symbols derives from the fact that the U channel transmitter in the CD channel decoder will transmit one symbol on average every 12 SPDIF channel bits. On this average rate, there is a maximum tolerance of 5%.

The SPDIF receiver is tolerant of symbol errors. Due to the physical nature of the transmission of the data over the CD disc, not more than 1 out of any 5 consecutive user channel symbols may be in error. The error may cause a change in data value, which is not detected by this interface, or it may cause a data symbol to be seen as a sync symbol, or a sync symbol to be seen as a data symbol. However, not more than 1 out of any 5 consecutive user channel symbols should be affected in this way.

The SPDIF U channel circuitry recognizes the 98-symbol packet structure, and sends the 96 symbol payload to the processor application. The 96 symbol payload is transmitted to the processor via 2 registers:

- The SPDIFRxUChannel register. In this register, data is presented 3 symbols at the time to the processor. Every time 3 new valid symbols, received on the SPDIF U Channel are present, the UChannelRxFull interrupt is asserted. For one 98-symbol packet, 96 symbols are carried across SPDIFRxUChannel. To transfer all this data, 32 UChannelRxFull interrupts are generated.
- The QChannelReceive register. In this register, only the Q bit of the packet is accumulated. Operation is similar to UChannelReceive. Because only Q-bit is transferred, only 96 Q-bits are transferred for any 98-symbol packet. To transfer this data, 4 QChannelRxFull interrupts are generated. When QChannelRxFull occurs, it is coincident with UChannelRxFull. There is only one QChannelRxFull for every 8 UChannelRxFull. The convention is that most significant data is transmitted first, and is left-aligned in the registers.
- Timing regarding packet boundary is extracted by hardware. The last UChannelRxFull corresponding to a given packet should be coincident with the last QChannelRxFull. In this last U, Q channel interrupt, symbols 95-98 are received, Q channel bits 67-98. The interrupts are coincident with UQSyncFound, flagging last symbols of the current frame.

- When the start of the new packet is found before the current packet is complete (less than 98 symbols in the packet), the UQFrameError interrupt is set. The application software should read out UChannelReceive and QchannelReceive registers, discard the value, and assume the start of a new packet.
- As already said, packet sync extraction is tolerant for single-symbol errors. Packet sync detection is based on the recognition of the sequence data-sync-sync-data in the symbol stream, because this is the only syncing sequence that is not affected by single errors. If the sync symbols are not found 98 symbols after the previous occurrence, it is assumed to be destroyed by channel error, and a new sync symbols is interpolated.
- Normally, only data bytes are passed to the application software. Every databyte will have its most significant bit set. If sync symbols are passed to the application software, they are seen as all-zero symbols. Sync symbols can only end up in the data stream due to channel error.
- **Behavior of U Channel receive interface on incoming non-CD data.**

This mode is selected if UsyncMode, bit 1 in register CD Text control is set '0'.

In non-CD mode, the SPDIF U channel stream is recognized as a sequence of "data symbols". No packet recognition is done.

Any sequence found in the SPDIF U channel stream starting with a leading one, followed by 7 information bits, is recognized as a "data symbol". Subsequent data symbols are separated by "pauses". During the "pause", "zero bits" are seen on the SPDIF U channel.

3 consecutive data symbols seen in the SPDIF U Channel stream are grouped together into the SPDIFRxUChannel register. First symbol is left, last symbol is right aligned. When SPDIFRxUChannel contains 3 new data symbols, UChannelRxFull is asserted.

In this mode, the operation of QchannelRx and associated interrupt QchannelRxFull is reserved, undefined. And the operation of UQFrameError and UQSyncFound is also reserved, undefined.

The U channel is extracted, and output by the SPDIF Rx on SPDIFRxUChannel-Stream.

When incoming SPDIF data parity error or bit error is detected, and if the next SPDIF word for that channel is error-free, the SPDIF word in error is replaced with the average of the previous word and next word. When incoming SPDIF data parity error or bit error is detected, and the next SPDIF word is in error, the previous SPDIF word is repeated.

### 39.5.1.4 Validity Flag Reception

An interrupt is associated with the Validity flag. (interrupt 16 - SPDIFValNoGood). This interrupt is set every time a frame is seen on the SPDIF interface with the validity bit set to "invalid".

### 39.5.1.5 SPDIF Receiver Interrupt Exception Definition

Several SPDIF exceptions can trigger an interrupt.

They are:

- Control Status channel change. Set when SPDIFRxChannel\_1 register is updated. The register is updated for every new C-Channel received. The exception is reset on write to InterruptClear register.
- SPDIF Illegal Symbol. Set on reception of illegal symbol during SPDIF receive. Reset by writing register InterruptClear.<sup>1</sup>
- SPDIF bit error. Set on reception of bit error. (Parity bit does not match). Reset on write to InterruptClear register.
- Receive data FIFO full. Set when SPDIF receive data FIFO is full.
- Receive data FIFO underrun/overrun. Set when there is a underrun/overrun on the SPDIF receive data FIFO.
- Receive data FIFO resynchronization. Set when a resynchronization event occurs on the SPDIF receive data FIFO.
- Receive U Channel buffer full. Set when next 24 bits of U channel code are available.
- Receive Q Channel buffer overrun. Set when Q channel buffer overrun.
- Receive U Channel buffer overrun. Set on U channel buffer overrun.
- Receive Q Channel buffer full. Set when next 24 bits of Q channel code are available.
- Receive UQ sync found. Set when UQ channel sync found.
- Receive UQ frame error. Set when UQ frame error found.

---

1. The SPDIF input is a biphas/mark modulated signal. The time between any two successive transitions of the SPDIF signal is always 1, 2 or 3 SPDIF symbol periods long. The SPDIF receiver will parse the stream, and split it in so-called symbols. It recognizes s1, s2 and s3 symbols, depending on the length of the symbols. Not all sequences of these symbols are allowed. To give an example, a sequence s2-s1-s1-s1-s2 cannot occur in a no-error SPDIF signal. If the receiver finds such an illegal sequence, the illegal symbol interrupt is set. No corrective action is undertaken. When the interrupt occurs, this means that(a) The SPDIF signal is destroyed by noise (b) The SPDIF frequency changed.

### 39.5.1.6 Standards Compliance

The SPDIF interface is compatible with the Tech 3250-E standard of the European Broadcasting Union, except clause 6.3.3 and the IEC60958-3 Ed2 for relevant topics.

Supported input frequency range is 12 KHz up to 96 KHz. (fully compliant) and 96 KHz up to 176 KHz (Can interface with compliant SPDIF transmitter within same cabinet, making reasonable assumptions on jitter added due to interconnecting wire.)

Tolerated jitter on SPDIF input signals are 0.25 bit peak-peak for high frequencies. There is no jitter limit for low frequencies. The user channel extraction in CD mode is capable of coping with single-symbol errors, and still retrieve U channel frames on correct boundaries. This capability is required for reliable reception of CD-Text from some Philips CD channel decoders. This capability was deemed more important than compliance with the IEC60958 annex A.3 standard, and for this reason user channel reception is not compliant with IEC60958 annex A.3. However, the interface is capable to receive U channel inserted by a typical CD channel decoder. Also, in this case, it is more robust and tolerant for channel error than what is required by IEC60958 annex A.3.

### 39.5.1.7 SPDIF PLOCK Detection and Rxclk Output

Using the high speed system clock, the internal DPLL can extract the bit clock (advanced pulse) from the input bitstream. When this internal DPLL is locked, the LOCK bit of PhaseConfig Register will be set, and the SPDIF Lock output pin SPDIF\_LOCK will be asserted.

After DPLL has locked, the pulses are generated, and the average pulse rate is 128 x the sampling frequency. (For a 44.1 KHz input sampling frequency, the average pulse rate = 128 x 44.1 KHz.) The pulse signal is used in the FreqMeas circuit to generate the frequency measurement result.

### 39.5.1.8 Measuring Frequency of SPDIF\_RxClk

The internal DPLL can extract the bit clock (advanced plus) from the input bitstream. To do that, it is necessary to measure the frequency of the incoming signal in relationship with the system clock (BUS\_CLK).

Associated with it are two registers, PhaseConfig and FreqMeas. The circuit will measure the frequency of the incoming clock as a function of the BUS\_CLK. The circuit is a second-order filter. The output is a value represented by an unsigned number stored in the 24-bit FreqMeas register, giving the frequency of the source as a function of the BUS\_CLK.

$\text{FreqMeas}[23:0] = \text{FreqMeas\_CLK} / \text{BUS\_CLK} * 2^{10} * \text{GAIN}$ .

For example, if the GAIN is selected as  $8 * (2^{10})$  ( $\text{PhaseConfig}[5:3] = 3'b011$ ), the actual result

$\text{FreqMeas\_CLK} / \text{BUS\_CLK}$  is equal to  $\text{FreqMeas}[23:0] / 2^{23}$ .

## 39.5.2 SPDIF Transmitter

Audio data for the SPDIF transmitter is provided by processor via the SPDIFTxLeft and SPDIFTxRight registers.

Clocking for SPDIF transmitter is selected through a multiplexer from several clock sources (see [TxClk\\_Source](#) for clock source inputs). The SPDIF transmitter clock source can be divided down as needed using Txclk\_DF. The SPDIF transmitter output can be chosen from either the SPDIF transmitter block, directly from the SPDIF receiver (via the output multiplexer), or disabled.

The SPDIF transmitter generates a SPDIF output bitstream in IEC60958 biphasic mark format, consisting of audio data, channel status.

### 39.5.2.1 Audio Data Transmission

Audio data for the SPDIF transmitter is provided by the processor via SPDIFTxLeft and SPDIFTxRight registers. They send audio data to Tx left and right FIFOs. The Tx left and right FIFOs are also 16-deep and 24-width (equal to the audio data width).

- **SPDIF transmitter data registers - Behavior on overrun, underrun**

The SPDIF Data Transmit registers (SPDIFTxLeft and SPDIFTxRight) have individual FIFOs for left and right channel. As a result, there is always the possibility that left and right FIFOs may go out of sync due to FIFO underruns and FIFO overruns that affect only one part (left or right) of any FIFO. To prevent this from happening, hardware has been added on the device. Two mechanisms to prevent mismatch between the FIFOs are available.

If SPDIF Tx FIFO underruns on the right half of the FIFO, no sample leaves that FIFO (because it was already empty). Special hardware will make sure that the next sample read from the left FIFO will not leave the FIFO (no read strobe is generated). If the underrun occurs on the left half of the FIFO, next read strobe to the right FIFO is blocked.

- **SPDIF transmitter data registers - Automatic resynchronization of FIFOs**

See [Audio Data Reception](#).

- **SPDIFTxLeft, SPDIFTxRight details**

With SPDIF Tx FIFOs three exceptions are associated.

- empty
- under/overrun
- resync

When the empty condition is set for processor data output registers, the processor should write data to the FIFO, before underrun occurs. When empty is set and, for instance, 6 samples need to be written, it is acceptable for the software to write first 6 samples from the LEFT address, followed by 6 samples from the RIGHT address, or 1 sample LEFT, followed by 1 sample RIGHT repeated 6 times. Left should be written before right. The implementation of all data out FIFOs is a double FIFO, one for left and one for right. Empty is set when both FIFOs are empty. Underrun, overrun are set when one of the FIFOs do underrun or do overrun. Resync is set when the hardware resynchronizes left and right FIFOs.

On receiving underrun, overrun interrupt, synchronization between Left and Right words in the FIFOs may be lost. Synchronization will not be lost when the underrun or overrun comes from the IEC60958 side of the FIFO. If the processor reads or writes more data from, for example, left than from right, synchronization will be lost. If automatic resynchronization is enabled, and if the software obeys the rules to let this work, resynchronization will be automatic.

### 39.5.2.2 Channel Status Transmission

A total of 48 Consumer channel status bits are transmitted from two registers. Channel Status Bits are ordered first bit left.

CS-channel MSB bit "0" is located in bit position 23 in the memory-mapped register SPDIFTxCChannelCons\_h. CS-channel bit "23" is considered bit 0 in the register. C-channel bits 24-47 are seen as MSB-LSB bits of register SPDIFTxCChannelCons\_l.

### 39.5.2.3 Validity Flag Transmission

The validity bit setting is performed via bit 5 of the SPDIF\_SCR register.

## 39.6 SPDIF Memory Map/Register Definition

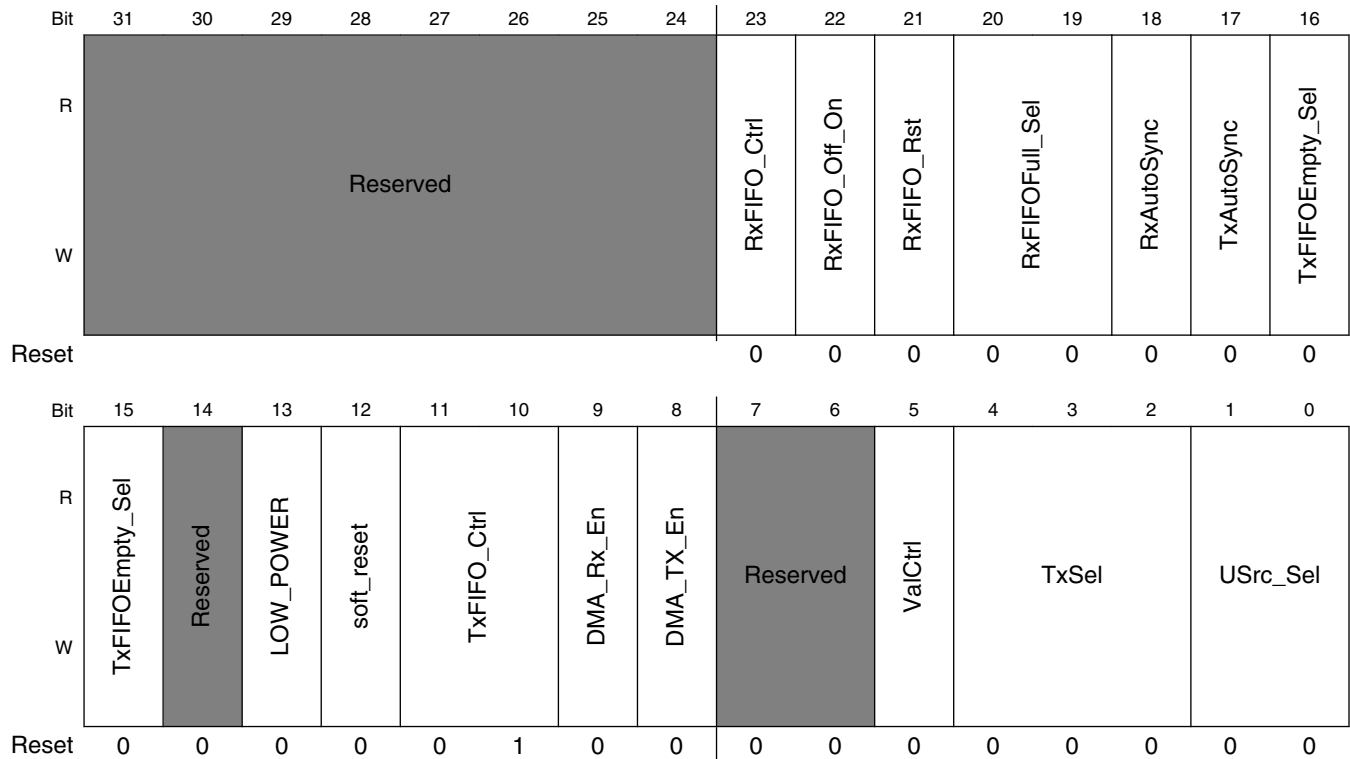

## SPDIF memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page

### 39.6.1 SPDIF Configuration Register (SPDIF\_SCR)

Address: 4038\_0000h base + 0h offset = 4038\_0000h

**SPDIF\_SCR field descriptions**

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
23 RxFIFO_Ctrl	0 Normal operation 1 Always read zero from Rx data register
22 RxFIFO_Off_On	0 SPDIF Rx FIFO is on 1 SPDIF Rx FIFO is off. Does not accept data from interface
21 RxFIFO_Rst	0 Normal operation 1 Reset register to 1 sample remaining
20–19 RxFIFOFull_Sel	00 Full interrupt if at least 1 sample in Rx left and right FIFOs 01 Full interrupt if at least 4 sample in Rx left and right FIFOs 10 Full interrupt if at least 8 sample in Rx left and right FIFOs 11 Full interrupt if at least 16 sample in Rx left and right FIFO
18 RxAutoSync	0 Rx FIFO auto sync off 1 RxFIFO auto sync on
17 TxAutoSync	0 Tx FIFO auto sync off 1 Tx FIFO auto sync on

Table continues on the next page...

## SPDIF\_SCR field descriptions (continued)

Field	Description
16–15 TxFIFOEmpty_Sel	00 Empty interrupt if 0 sample in Tx left and right FIFOs 01 Empty interrupt if at most 4 sample in Tx left and right FIFOs 10 Empty interrupt if at most 8 sample in Tx left and right FIFOs 11 Empty interrupt if at most 12 sample in Tx left and right FIFOs
14 -	This field is reserved. Reserved
13 LOW_POWER	When write 1 to this bit, it will cause SPDIF enter low-power mode. return 1 when SPDIF in Low-Power mode.
12 soft_reset	When write 1 to this bit, it will cause SPDIF software reset. The software reset will last 8 cycles. When in the reset process, return 1 when read. else return 0 when read.
11–10 TxFIFO_Ctrl	00 Send out digital zero on SPDIF Tx 01 Tx Normal operation 10 Reset to 1 sample remaining 11 Reserved
9 DMA_Rx_En	DMA Receive Request Enable (RX FIFO full)
8 DMA_TX_En	DMA Transmit Request Enable (Tx FIFO empty)
7–6 -	This field is reserved. Reserved
5 ValCtrl	0 Outgoing Validity always set 1 Outgoing Validity always clear
4–2 TxSel	000 Off and output 0 001 Feed-through SPDIFIN 101 Tx Normal operation Others Reserved
USrc_Sel	00 No embedded U channel 01 U channel from SPDIF receive block (CD mode) 10 Reserved 11 U channel from on chip transmitter

### 39.6.2 CDText Control Register (SPDIF\_SRCD)

Address: 4038\_0000h base + 4h offset = 4038\_0004h

#### SPDIF\_SRCD field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
23–15 Reserved	This read-only field is reserved and always has the value 0.
14–8 -	This field is reserved. Reserved. set to zero.
7–3 Reserved	This read-only field is reserved and always has the value 0.
2 -	This field is reserved. Reserved.
1 USyncMode	0 Non-CD data 1 CD user channel subcode
0 -	This field is reserved. Reserved.

### 39.6.3 PhaseConfig Register (SPDIF\_SRPC)

Address: 4038\_0000h base + 8h offset = 4038\_0008h

#### SPDIF\_SRPC field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
23–11 Reserved	This read-only field is reserved and always has the value 0.
10–7 ClkSrc_Sel	Clock source selection, all other settings not shown are reserved: 0000 if (DPLL Locked) SPDIF_RxCk else REF_CLK_32K (XTALOSC) 0001 if (DPLL Locked) SPDIF_RxCk else tx_clk (SPDIF0_CLK_ROOT) 0011 if (DPLL Locked) SPDIF_RxCk else SPDIF_EXT_CLK 0101 REF_CLK_32K (XTALOSC) 0110 tx_clk (SPDIF0_CLK_ROOT) 1000 SPDIF_EXT_CLK
6 LOCK	LOCK bit to show that the internal DPLL is locked, read only
5–3 GainSel	Gain selection: 000 24*(2**10) 001 16*(2**10)

Table continues on the next page...

## SPDIF\_SRPC field descriptions (continued)

Field	Description
	010 12*(2**10) 011 8*(2**10) 100 6*(2**10) 101 4*(2**10) 110 3*(2**10)
Reserved	This read-only field is reserved and always has the value 0.

## 39.6.4 InterruptEn Register (SPDIF\_SIE)

The InterruptEn register (SPDIF\_SIE) provides control over the enabling of interrupts.

Address: 4038\_0000h base + Ch offset = 4038\_000Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
R	Reserved								0	Reserved			Lock	TxUnOv	TxResyn	CNew	ValNoGood
W	Reserved									Reserved							
Reset									0	0	0	0	0	0	0	0	
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
R	SymErr	BitErr	Reserved				URxFul	URxOv	QRxFul	QRxOv	UQSync	UQEir	RxFIFOUnOv	RxFIFOResyn	LockLoss	TxErn	RxFIFOFul
W			Reserved														
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

## SPDIF\_SIE field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
23 Reserved	This read-only field is reserved and always has the value 0.
22–21 -	This field is reserved. Reserved. set to zero.
20 Lock	SPDIF receiver's DPLL is locked
19 TxUnOv	SPDIF Tx FIFO under/overrun

Table continues on the next page...

## SPDIF\_SIE field descriptions (continued)

Field	Description
18 TxResyn	SPDIF Tx FIFO resync
17 CNew	SPDIF receive change in value of control channel
16 ValNoGood	SPDIF validity flag no good
15 SymErr	SPDIF receiver found illegal symbol
14 BitErr	SPDIF receiver found parity bit error
13–11 -	This field is reserved. Reserved. set to zero.
10 URxFul	U Channel receive register full, can't be cleared with reg. IntClear. To clear it, read from U Rx reg.
9 URxOv	U Channel receive register overrun
8 QRxFul	Q Channel receive register full, can't be cleared with reg. IntClear. To clear it, read from Q Rx reg.
7 QRxOv	Q Channel receive register overrun
6 UQSync	U/Q Channel sync found
5 UQErr	U/Q Channel framing error
4 RxFIFOUnOv	Rx FIFO underrun/overrun
3 RxFIFOResyn	Rx FIFO resync
2 LockLoss	SPDIF receiver loss of lock
1 TxEm	SPDIF Tx FIFO empty, can't be cleared with reg. IntClear. To clear it, write toTx FIFO.
0 RxFIFOFull	SPDIF Rx FIFO full, can't be cleared with reg. IntClear. To clear it, read from Rx FIFO.

### 39.6.5 InterruptStat Register (SPDIF\_SIS)

The InterruptStat (SPDIF\_SIS) register is a read only register that provides the status on interrupt operations.

Address: 4038\_0000h base + 10h offset = 4038\_0010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved								0	Lock	TxUnOv	TxResyn	CNew	ValNoGood		
W	Reserved								Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved
Reset	0								0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	SymErr	BitErr	0	0	0	URxFul	URxOv	QRxFul	QRxOv	UQSync	UQErr	RxFIFOUnOv	RxFIFOResyn	LockLoss	TxErn	RxFIFOFull
W	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

## SPDIF\_SIS field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
23–21 Reserved	This read-only field is reserved and always has the value 0.
20 Lock	SPDIF receiver's DPLL is locked
19 TxUnOv	SPDIF Tx FIFO under/overflow
18 TxResyn	SPDIF Tx FIFO resync
17 CNew	SPDIF receive change in value of control channel
16 ValNoGood	SPDIF validity flag no good
15 SymErr	SPDIF receiver found illegal symbol
14 BitErr	SPDIF receiver found parity bit error
13–11 Reserved	This read-only field is reserved and always has the value 0.
10 URxFul	U Channel receive register full, can't be cleared with reg. IntClear. To clear it, read from U Rx reg.
9 URxOv	U Channel receive register overrun
8 QRxFul	Q Channel receive register full, can't be cleared with reg. IntClear. To clear it, read from Q Rx reg.
7 QRxOv	Q Channel receive register overrun
6 UQSync	U/Q Channel sync found
5 UQErr	U/Q Channel framing error
4 RxFIFOUnOv	Rx FIFO underrun/overflow
3 RxFIFOResyn	Rx FIFO resync
2 LockLoss	SPDIF receiver loss of lock
1 TxEm	SPDIF Tx FIFO empty, can't be cleared with reg. IntClear. To clear it, write to Tx FIFO.
0 RxFIFOFull	SPDIF Rx FIFO full, can't be cleared with reg. IntClear. To clear it, read from Rx FIFO.

### 39.6.6 InterruptClear Register (SPDIF\_SIC)

The InterruptClear (SPDIF\_SIC) register is a write only register and is used to clear interrupts.

Address: 4038\_0000h base + 10h offset = 4038\_0010h

**SPDIF\_SIC field descriptions**

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
23–21 Reserved	This read-only field is reserved and always has the value 0.
20 Lock	SPDIF receiver's DPLL is locked
19 TxUnOv	SPDIF Tx FIFO under/overflow

Table continues on the next page...

**SPDIF\_SIC field descriptions (continued)**

Field	Description
18 TxResyn	SPDIF Tx FIFO resync
17 CNew	SPDIF receive change in value of control channel
16 ValNoGood	SPDIF validity flag no good
15 SymErr	SPDIF receiver found illegal symbol
14 BitErr	SPDIF receiver found parity bit error
13–10 -	This field is reserved. Reserved.
9 URxOv	U Channel receive register overrun
8 -	Reserved
7 QRxOv	Q Channel receive register overrun
6 UQSync	U/Q Channel sync found
5 UQErr	U/Q Channel framing error
4 RxFIFOUnOv	Rx FIFO underrun/overrun
3 RxFIFOResyn	Rx FIFO resync
2 LockLoss	SPDIF receiver loss of lock
-	This field is reserved. Reserved.

**39.6.7 SPDIFRxLeft Register (SPDIF\_SRL)**

SPDIFRxLeft register is an audio data reception register.

Address: 4038\_0000h base + 14h offset = 4038\_0014h

### SPDIF\_SRL field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
RxDataLeft	Processor receive SPDIF data left

### 39.6.8 SPDIFRxRight Register (SPDIF\_SRR)

SPDIFRxRight register is an audio data reception register.

Address: 4038\_0000h base + 18h offset = 4038\_0018h

### SPDIF\_SRR field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
RxDataRight	Processor receive SPDIF data right

### 39.6.9 SPDIFRxCChannel\_h Register (SPDIF\_SRC SH)

SPDIFRxCChannel\_h register is a channel status reception register.

Address: 4038\_0000h base + 1Ch offset = 4038\_001Ch

### SPDIF\_SRC SH field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented.

Table continues on the next page...

**SPDIF\_SRC SH field descriptions (continued)**

Field	Description
	This field is reserved.
RxCChannel_h	SPDIF receive C channel register, contains first 24 bits of C channel without interpretation

**39.6.10 SPDIFRxCChannel\_I Register (SPDIF\_SRC SL)**

SPDIFRxCChannel\_I register is a channel status reception register.

Address: 4038\_0000h base + 20h offset = 4038\_0020h

**SPDIF\_SRC SL field descriptions**

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
RxCChannel_I	SPDIF receive C channel register, contains next 24 bits of C channel without interpretation

**39.6.11 UchannelRx Register (SPDIF\_SR U)**

UchannelRx register is a user bits reception register.

Address: 4038\_0000h base + 24h offset = 4038\_0024h

**SPDIF\_SR U field descriptions**

Field	Description
31–24 [unimplemented]	This field is reserved. This is a 24-bit register the upper byte is unimplemented.
RxUChannel	SPDIF receive U channel register, contains next 3 U channel bytes

### 39.6.12 QchannelRx Register (SPDIF\_SRQ)

QChannelRx register is a user bits reception register.

Address: 4038\_0000h base + 28h offset = 4038\_0028h

#### SPDIF\_SRQ field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
RxQChannel	SPDIF receive Q channel register, contains next 3 Q channel bytes

### 39.6.13 SPDIFTxLeft Register (SPDIF\_STL)

SPDIFTxLeft register is an audio data transmission register.

Address: 4038\_0000h base + 2Ch offset = 4038\_002Ch

#### SPDIF\_STL field descriptions

Field	Description
31–24 [unimplemented]	This field is reserved. This is a 24-bit register the upper byte is unimplemented.
TxDataLeft	SPDIF transmit left channel data. It is write-only, and always returns zeros when read

### 39.6.14 SPDIFTxRight Register (SPDIF\_STR)

SPDIFTxRight register is an audio data transmission register.

Address: 4038\_0000h base + 30h offset = 4038\_0030h

#### SPDIF\_STR field descriptions

Field	Description
31–24 [unimplemented]	This field is reserved. This is a 24-bit register the upper byte is unimplemented.
TxDataRight	SPDIF transmit right channel data. It is write-only, and always returns zeros when read

### 39.6.15 SPDIFTxCChannelCons\_h Register (SPDIF\_STCSCH)

SPDIFTxCChannelCons\_h register is a channel status transmission register.

Address: 4038\_0000h base + 34h offset = 4038\_0034h

#### SPDIF\_STCSCH field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
TxCChannelCons_h	SPDIF transmit Cons. C channel data, contains first 24 bits without interpretation. When read, it returns the latest data written by the processor

### 39.6.16 SPDIFTxChannelCons\_I Register (SPDIF\_STCSCL)

SPDIFTxChannelCons\_I register is a channel status transmission register.

Address: 4038\_0000h base + 38h offset = 4038\_0038h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved								TxChannelCons_I																							
W	Reserved								TxChannelCons_I																							
Reset	0 0 0 0 0 0 0 0								0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0																							

#### SPDIF\_STCSCL field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
TxChannelCons_I	SPDIF transmit Cons. C channel data, contains next 24 bits without interpretation. When read, it returns the latest data written by the processor

### 39.6.17 FreqMeas Register (SPDIF\_SRFM)

Address: 4038\_0000h base + 44h offset = 4038\_0044h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved								FreqMeas																							
W	Reserved								FreqMeas																							
Reset	0 0 0 0 0 0 0 0								0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0																							

#### SPDIF\_SRFM field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
FreqMeas	Frequency measurement data

### 39.6.18 SPDIFTxClk Register (SPDIF\_STC)

The SPDIFTxClk Control register includes the means to select the transmit clock and frequency division.

Address: 4038\_0000h base + 50h offset = 4038\_0050h

#### SPDIF\_STC field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
23–20 Reserved	This read-only field is reserved and always has the value 0.
19–11 SYSCLK_DF	system clock divider factor, 2~512. 0 no clock signal 1 divider factor is 2 ... .. 511 divider factor is 512
10–8 TxClk_Source	000 XTALOSC input (XTALOSC clock) 001 tx_clk input (from SPDIF0_CLK_ROOT. See CCM.) 010 tx_clk1 (from SAI1) 011 tx_clk2 SPDIF_EXT_CLK, from pads 100 tx_clk3 (from SAI2) 101 ipg_clk input (frequency divided) 110 tx_clk4 (from SAI3)
7 tx_all_clk_en	Spdif transfer clock enable. When data is going to be transfered, this bit should be set to1.

Table continues on the next page...

**SPDIF\_STC field descriptions (continued)**

Field	Description
	0 disable transfer clock. 1 enable transfer clock.
TxClk_DF	Divider factor (1-128)  0 divider factor is 1 1 divider factor is 2 ... .. 127 divider factor is 128

# Chapter 40

## 10/100 /1000 -Mbps Ethernet MAC (ENET)

### 40.2 Introduction

The MAC-NET core, in conjunction with a 10/100-Mbit/s MAC, implements layer 3 network acceleration functions. These functions are designed to accelerate the processing of various common networking protocols, such as IP, TCP, UDP, and ICMP, providing wire speed services to client applications.

### 40.3 Overview

The core implements a dual-speed 10/100-Mbit/s Ethernet MAC compliant with the IEEE802.3-2002 standard. The MAC layer provides compatibility with half- or full-duplex 10/100-Mbit/s Ethernet LANs.

The MAC operation is fully programmable and can be used in Network Interface Card (NIC), bridging, or switching applications. The core implements the remote network monitoring (RMON) counters according to IETF RFC 2819.

The core also implements a hardware acceleration block to optimize the performance of network controllers providing TCP/IP, UDP, and ICMP protocol services. The acceleration block performs critical functions in hardware, which are typically implemented with large software overhead.

The core implements programmable embedded FIFOs that can provide buffering on the receive path for lossless flow control.

Advanced power management features are available with magic packet detection and programmable power-down modes.

A unified DMA (uDMA), internal to the ENET module, optimizes data transfer between the ENET core and the SoC, and supports an enhanced buffer descriptor programming model to support IEEE 1588 functionality.

The programmable Ethernet MAC with IEEE 1588 integrates a standard IEEE 802.3 Ethernet MAC with a time-stamping module. The IEEE 1588 standard provides accurate clock synchronization for distributed control nodes for industrial automation applications.

## **40.3.1 Features**

The MAC-NET core includes the following features.

### **40.3.1.1 Ethernet MAC features**

- Implements the full 802.3 specification with preamble/SFD generation, frame padding generation, CRC generation and checking
- Supports zero-length preamble
- Dynamically configurable to support 10/100-Mbit/s operation
- Supports 10/100 Mbit/s full-duplex and configurable half-duplex operation
- Compliant with the AMD magic packet detection with interrupt for node remote power management
- Seamless interface to commercial ethernet PHY devices via one of the following:
  - a 4-bit Media Independent Interface (MII) operating at 2.5/25 MHz.
  - a 4-bit non-standard MII-Lite (MII without the CRS and COL signals) operating at 2.5/25 MHz.
  - a 2-bit Reduced MII (RMII) operating at 50 MHz.
- Simple 64-Bit FIFO user-application interface

- CRC-32 checking at full speed with optional forwarding of the frame check sequence (FCS) field to the client
- CRC-32 generation and append on transmit or forwarding of user application provided FCS selectable on a per-frame basis
- In full-duplex mode:
  - Implements automated pause frame (802.3 x31A) generation and termination, providing flow control without user application intervention
  - Pause quanta used to form pause frames — dynamically programmable
  - Pause frame generation additionally controllable by user application offering flexible traffic flow control
  - Optional forwarding of received pause frames to the user application
  - Implements standard flow-control mechanism
- In half-duplex mode: provides full collision support, including jamming, backoff, and automatic retransmission
- Supports VLAN-tagged frames according to IEEE 802.1Q
- Programmable MAC address: Insertion on transmit; discards frames with mismatching destination address on receive (except broadcast and pause frames)
- Programmable promiscuous mode support to omit MAC destination address checking on receive
- Multicast and unicast address filtering on receive based on 64-entry hash table, reducing higher layer processing load
- Programmable frame maximum length providing support for any standard or proprietary frame length
- Statistics indicators for frame traffic and errors (alignment, CRC, length) and pause frames providing for IEEE 802.3 basic and mandatory management information database (MIB) package and remote network monitoring (RFC 2819)
- Simple handshake user application FIFO interface with fully programmable depth and threshold levels
- Provides separate status word for each received frame on the user interface providing information such as frame length, frame type, VLAN tag, and error information
- Multiple internal loopback options
- MDIO master interface for PHY device configuration and management supports two programmable MDIO base addresses, and standard (IEEE 802.3 Clause 22) and extended (Clause 45) MDIO frame formats
- Supports legacy FEC buffer descriptors
- Interrupt coalescing reduces the number of interrupts generated by the MAC, reducing CPU loading

### 40.3.1.2 IP protocol performance optimization features

- Operates on TCP/IP and UDP/IP and ICMP/IP protocol data or IP header only
- Enables wire-speed processing
- Supports IPv4 and IPv6
- Transparent passing of frames of other types and protocols
- Supports VLAN tagged frames according to IEEE 802.1q with transparent forwarding of VLAN tag and control field
- Automatic IP-header and payload (protocol specific) checksum calculation and verification on receive
- Automatic IP-header and payload (protocol specific) checksum generation and automatic insertion on transmit configurable on a per-frame basis
- Supports IP and TCP, UDP, ICMP data for checksum generation and checking
- Supports full header options for IPv4 and TCP protocol headers
- Provides IPv6 support to datagrams with base header only — datagrams with extension headers are passed transparently unmodified/unchecked
- Provides statistics information for received IP and protocol errors
- Configurable automatic discard of erroneous frames
- Configurable automatic host-to-network (RX) and network-to-host (TX) byte order conversion for IP and TCP/UDP/ICMP headers within the frame
- Configurable padding remove for short IP datagrams on receive
- Configurable Ethernet payload alignment to allow for 32-bit word-aligned header and payload processing
- Programmable store-and-forward operation with clock and rate decoupling FIFOs

### 40.3.1.3 IEEE 1588 features

- Supports all IEEE 1588 frames.
- Allows reference clock to be chosen independently of network speed.
- Software-programmable precise time-stamping of ingress and egress frames

- Timer monitoring capabilities for system calibration and timing accuracy management
- Precise time-stamping of external events with programmable interrupt generation
- Programmable event and interrupt generation for external system control
- Supports hardware- and software-controllable timer synchronization.
- Provides a 4-channel IEEE 1588 timer. Each channel supports input capture and output compare using the 1588 counter.

### 40.3.2 Block diagram

Figure 40-1. Ethernet MAC-NET core block diagram

## 40.4 External Signals

The table found here describes the external signals of ENET.

**Table 40-2. ENET External Signals**

Signal	Description	Mode	Pad	Mode	Direction
ENET_MDC	Output clock provides a timing reference to the PHY for data transfers on the MDIO signal.	MII/RMII/RGMII	GPIO_B1_14	ALT0	O
			GPIO_AD_B1_04	ALT1	
			GPIO_EMC_40	ALT4	
ENET_MDIO	Transfers control information between the external PHY and the media-access controller. Data is synchronous to MDC. This signal is an input after reset.	MII/RMII/RGMII	GPIO_B1_15	ALT0	IO
			GPIO_AD_B1_05	ALT1	
			GPIO_EMC_41	ALT4	
ENET_TX_DATA0	Serial output Ethernet data. Only valid during TX_EN assertion.	MII/RMII	GPIO_B1_07	ALT3	O
			GPIO_EMC_22	ALT3	
ENET_TX_DATA1	Serial output Ethernet data. Only valid during TX_EN assertion.	MII/RMII	GPIO_EMC_21	ALT3	O
			GPIO_B1_08	ALT3	
ENET_TX_DATA2	Serial output Ethernet data. Only valid during TX_EN assertion.	MII	GPIO_AD_B0_05	ALT2	O
ENET_TX_DATA3	Serial output Ethernet data. Only valid during TX_EN assertion.	MII	GPIO_AD_B0_04	ALT2	O
ENET_TX_ER	When asserted for one or more clock cycles while TXEN is also asserted, PHY sends one or more illegal symbols.	MII/RMII	GPIO_AD_B0_07	ALT2	O
ENET_TX_EN	Indicates when valid nibbles are present on the MII. This signal is asserted with the first nibble of a preamble and is	MII/RMII	GPIO_B1_09	ALT3	O
			GPIO_EMC_24	ALT3	

*Table continues on the next page...*

**Table 40-2. ENET External Signals (continued)**

Signal	Description	Mode	Pad	Mode	Direction
	deasserted before the first TX_CLK following the final nibble of the frame.				
ENET_TX_CLK	Input clock In MII mode, provides a timing reference for TX_EN, TX_DATA[3:0], and TX_ER. IN RGMII mode, provides the external 125 MHz reference clock input.	MII/RGMII	GPIO_B1_10	ALT3	I
			GPIO_EMC_25	ALT3	
ENET_RX_DATA0	Contains the Ethernet input data transferred from the PHY to the media-access controller when RX_EN is asserted.	MII/RMII	GPIO_EMC_20	ALT3	I
			GPIO_B1_04	ALT3	
ENET_RX_DATA1	Contains the Ethernet input data transferred from the PHY to the media-access controller when RX_EN is asserted.	MII/RMII	GPIO_EMC_19	ALT3	I
			GPIO_B1_05	ALT3	
ENET_RX_DATA2	Contains the Ethernet input data transferred from the PHY to the media-access controller when RX_EN is asserted.	MII	GPIO_AD_B0_09	ALT2	I
ENET_RX_DATA3	Contains the Ethernet input data transferred from the PHY to the media-access controller when RX_EN is asserted.	MII	GPIO_AD_B0_08	ALT2	I
ENET_RX_ER	When asserted with RXDV, indicates the PHY detects an error in the current frame.	MII/RMII	GPIO_B1_11	ALT3	I
			GPIO_EMC_26	ALT3	
ENET_RX_EN	Asserting this input indicates the PHY has valid nibbles present on the MII. RX_EN must remain asserted	MII/RMII	GPIO_EMC_23	ALT3	I
			GPIO_B1_06	ALT3	

Table continues on the next page...

Table 40-2. ENET External Signals (continued)

Signal	Description	Mode	Pad	Mode	Direction
	<p>from the first recovered nibble of the frame through to the last nibble. Asserting RX_EN must start no later than the SFD and exclude any EOF. In RMII mode, this pin also generates the CRS signal.</p> <p><b>NOTE:</b> This pin functions as RMII_CRS_DV when RMII mode register is set.</p>				
ENET_RX_CLK	Input clock In MII mode, provides a timing reference for TX_EN, TX_DATA[3:0], and TX_ER. IN RGMII mode, provides the external 125 MHz reference clock input.	MII	GPIO_AD_B0_06	ALT2	I
ENET_CRS	Carrier sense. When asserted, indicates transmit or receive medium is not idle. In RMII mode, this signal is present on the RMII_CRS_DV pin.	MII	GPIO_AD_B0_10	ALT2	I
ENET_COL	Asserted upon detection of a collision and remains asserted while the collision persists. This signal is not defined for full duplex mode.	MII	GPIO_AD_B0_11	ALT2	I
ENET_REF_CLK	In RMII mode, this signal is the reference clock for receive, transmit, and the control interface.	RMII	GPIO_EMC_25	ALT4	I
			GPIO_B1_10	ALT6	
ENET_1588_EVEN T0_OUT	Capture/compare block input/output event bus signal. When configured	MII/RMII/RGMII	GPIO_AD_B0_14	ALT3	O
			GPIO_AD_B0_10	ALT7	
			GPIO_B1_13	ALT3	

Table continues on the next page...

**Table 40-2. ENET External Signals (continued)**

Signal	Description	Mode	Pad	Mode	Direction
	for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRn register for inspection by software. When configured for compare, the corresponding signal 1588_EVENT is asserted for one cycle when the timer reaches the compare value programmed in register ENET_TCCRn. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set. ENET_1588_EVENT0_OUT has a programmable output width, see IOMUXC_GPR0[CLK_STRETCH], delayed one clock cycle in relation to all other EVENTx_OUT signals.				
ENET_1588_EVENT0_IN	Capture/compare block input/output event bus signal. ## 40.5 Clocks

The table found here describes the clock sources for ENET. Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information.

**Table 40-3. ENET Clocks**

Clock name	Clock Root	Description
ipg_clk	ipg_clk_root	Module clock
ipg_clk_mac0	ipg_clk_root	MAC peripheral clock
ipg_clk_mac0_s	ipg_clk_root	MAC peripheral access clock
ipg_clk_s	ipg_clk_root	Peripheral access clock
ipg_clk_time	ref_enetpll2_clk	Peripheral clock
mem_mac0_mem_clk	ipg_clk_root	MAC memory clock

## 40.6 Memory map/register definition

ENET registers must be read or written with 32-bit accesses. Non-32 bit accesses will terminate with an error.

Reserved bits should be written with 0 and ignored on read. Unused registers read zero and a write has no effect.

This table shows Ethernet registers organization.

**Table 40-4. Register map summary**

Offset Address	Section	Description
0x0000 – 0x01FF	Configuration	Core control and status registers
0x0200 – 0x03FF	Statistics counters	MIB and Remote Network Monitoring (RFC 2819) registers
0x0400 – 0x0430	1588 control	1588 adjustable timer (TSM) and 1588 frame control
0x0600 – 0x07FC	Capture/Compare block	Registers for the Capture/Compare block

**ENET memory map**

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
402D_4004	Interrupt Event Register (ENET2_EIR)	32	w1c	0000_0000h	<a href="#">40.6.1/2174</a>
402D_4008	Interrupt Mask Register (ENET2_EIMR)	32	R/W	0000_0000h	<a href="#">40.6.2/2177</a>
402D_4010	Receive Descriptor Active Register (ENET2_RDAR)	32	R/W	0000_0000h	<a href="#">40.6.3/2180</a>
402D_4014	Transmit Descriptor Active Register (ENET2_TDAR)	32	R/W	0000_0000h	<a href="#">40.6.4/2180</a>
402D_4024	Ethernet Control Register (ENET2_ECR)	32	R/W	<a href="#">See section</a>	<a href="#">40.6.5/2181</a>
402D_4040	MII Management Frame Register (ENET2_MMFR)	32	R/W	0000_0000h	<a href="#">40.6.6/2183</a>
402D_4044	MII Speed Control Register (ENET2_MSCR)	32	R/W	0000_0000h	<a href="#">40.6.7/2184</a>
402D_4064	MIB Control Register (ENET2_MIBC)	32	R/W	C000_0000h	<a href="#">40.6.8/2186</a>
402D_4084	Receive Control Register (ENET2_RCR)	32	R/W	05EE_0001h	<a href="#">40.6.9/2187</a>
402D_40C4	Transmit Control Register (ENET2_TCR)	32	R/W	0000_0000h	<a href="#">40.6.10/2190</a>
402D_40E4	Physical Address Lower Register (ENET2_PALR)	32	R/W	0000_0000h	<a href="#">40.6.11/2192</a>
402D_40E8	Physical Address Upper Register (ENET2_PAUR)	32	R/W	0000_8808h	<a href="#">40.6.12/2192</a>
402D_40EC	Opcode/Pause Duration Register (ENET2_OPD)	32	R/W	0001_0000h	<a href="#">40.6.13/2193</a>
402D_40F0	Transmit Interrupt Coalescing Register (ENET2_TXIC)	32	R/W	0000_0000h	<a href="#">40.6.14/2193</a>
402D_4100	Receive Interrupt Coalescing Register (ENET2_RXIC)	32	R/W	0000_0000h	<a href="#">40.6.15/2194</a>
402D_4118	Descriptor Individual Upper Address Register (ENET2_IUR)	32	R/W	0000_0000h	<a href="#">40.6.16/2195</a>
402D_411C	Descriptor Individual Lower Address Register (ENET2_IALR)	32	R/W	0000_0000h	<a href="#">40.6.17/2196</a>
402D_4120	Descriptor Group Upper Address Register (ENET2_GAUR)	32	R/W	0000_0000h	<a href="#">40.6.18/2196</a>
402D_4124	Descriptor Group Lower Address Register (ENET2_GALR)	32	R/W	0000_0000h	<a href="#">40.6.19/2197</a>
402D_4144	Transmit FIFO Watermark Register (ENET2_TFWR)	32	R/W	0000_0000h	<a href="#">40.6.20/2197</a>
402D_4180	Receive Descriptor Ring Start Register (ENET2_RDSR)	32	R/W	0000_0000h	<a href="#">40.6.21/2198</a>

*Table continues on the next page...*

## ENET memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
402D_4184	Transmit Buffer Descriptor Ring Start Register (ENET2_TDSR)	32	R/W	0000_0000h	<a href="#">40.6.22/2199</a>
402D_4188	Maximum Receive Buffer Size Register (ENET2_MRBR)	32	R/W	0000_0000h	<a href="#">40.6.23/2200</a>
402D_4190	Receive FIFO Section Full Threshold (ENET2_RSFL)	32	R/W	0000_0000h	<a href="#">40.6.24/2201</a>
402D_4194	Receive FIFO Section Empty Threshold (ENET2_RSEM)	32	R/W	0000_0000h	<a href="#">40.6.25/2201</a>
402D_4198	Receive FIFO Almost Empty Threshold (ENET2_RAEM)	32	R/W	0000_0004h	<a href="#">40.6.26/2202</a>
402D_419C	Receive FIFO Almost Full Threshold (ENET2_RAFL)	32	R/W	0000_0004h	<a href="#">40.6.27/2202</a>
402D_41A0	Transmit FIFO Section Empty Threshold (ENET2_TSEM)	32	R/W	0000_0000h	<a href="#">40.6.28/2203</a>
402D_41A4	Transmit FIFO Almost Empty Threshold (ENET2_TAEM)	32	R/W	0000_0004h	<a href="#">40.6.29/2203</a>
402D_41A8	Transmit FIFO Almost Full Threshold (ENET2_TAFL)	32	R/W	0000_0008h	<a href="#">40.6.30/2204</a>
402D_41AC	Transmit Inter-Packet Gap (ENET2_TIPG)	32	R/W	0000_000Ch	<a href="#">40.6.31/2204</a>
402D_41B0	Frame Truncation Length (ENET2_FTRL)	32	R/W	0000_07FFh	<a href="#">40.6.32/2205</a>
402D_41C0	Transmit Accelerator Function Configuration (ENET2_TACC)	32	R/W	0000_0000h	<a href="#">40.6.33/2205</a>
402D_41C4	Receive Accelerator Function Configuration (ENET2_RACC)	32	R/W	0000_0000h	<a href="#">40.6.34/2206</a>
402D_4200	Reserved Statistic Register (ENET2_RMON_T_DROP)	32	R	0000_0000h	<a href="#">40.6.35/2207</a>
402D_4204	Tx Packet Count Statistic Register (ENET2_RMON_T_PACKETS)	32	R	0000_0000h	<a href="#">40.6.36/2208</a>
402D_4208	Tx Broadcast Packets Statistic Register (ENET2_RMON_T_BC_PKT)	32	R	0000_0000h	<a href="#">40.6.37/2208</a>
402D_420C	Tx Multicast Packets Statistic Register (ENET2_RMON_T_MC_PKT)	32	R	0000_0000h	<a href="#">40.6.38/2209</a>
402D_4210	Tx Packets with CRC/Align Error Statistic Register (ENET2_RMON_T_CRC_ALIGN)	32	R	0000_0000h	<a href="#">40.6.39/2209</a>
402D_4214	Tx Packets Less Than Bytes and Good CRC Statistic Register (ENET2_RMON_T_UNDERSIZE)	32	R	0000_0000h	<a href="#">40.6.40/2209</a>
402D_4218	Tx Packets GT MAX_FL bytes and Good CRC Statistic Register (ENET2_RMON_T_OVERSIZE)	32	R	0000_0000h	<a href="#">40.6.41/2210</a>
402D_421C	Tx Packets Less Than 64 Bytes and Bad CRC Statistic Register (ENET2_RMON_T_FRAG)	32	R	0000_0000h	<a href="#">40.6.42/2210</a>
402D_4220	Tx Packets Greater Than MAX_FL bytes and Bad CRC Statistic Register (ENET2_RMON_T_JAB)	32	R	0000_0000h	<a href="#">40.6.43/2211</a>

Table continues on the next page...

## ENET memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page

### 40.6.1 Interrupt Event Register (ENETx\_EIR)

When an event occurs that sets a bit in EIR, an interrupt occurs if the corresponding bit in the interrupt mask register (EIMR) is also set. Writing a 1 to an EIR bit clears it; writing 0 has no effect. This register is cleared upon hardware reset.

#### NOTE

TxBD[INT] and RxBD[INT] must be set to 1 to allow setting the corresponding EIR register flags in enhanced mode, ENET\_ECR[EN1588] = 1. Legacy mode does not require these flags to be enabled.

Address: 402D\_4000h base + 4h offset = 402D\_4004h

**ENETx\_EIR field descriptions**

Field	Description
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 BABR	Babbling Receive Error Indicates a frame was received with length in excess of RCR[MAX_FL] bytes.
29 BABT	Babbling Transmit Error Indicates the transmitted frame length exceeds RCR[MAX_FL] bytes. Usually this condition is caused when a frame that is too long is placed into the transmit data buffer(s). Truncation does not occur.
28 GRA	Graceful Stop Complete This interrupt is asserted after the transmitter is put into a pause state after completion of the frame currently being transmitted. See Graceful Transmit Stop (GTS) for conditions that lead to graceful stop. <b>NOTE:</b> The GRA interrupt is asserted only when the TX transitions into the stopped state. If this bit is cleared by writing 1 and the TX is still stopped, the bit is not set again.
27 TXF	Transmit Frame Interrupt Indicates a frame has been transmitted and the last corresponding buffer descriptor has been updated.
26 TXB	Transmit Buffer Interrupt Indicates a transmit buffer descriptor has been updated.
25 RXF	Receive Frame Interrupt Indicates a frame has been received and the last corresponding buffer descriptor has been updated.
24 RXB	Receive Buffer Interrupt Indicates a receive buffer descriptor is not the last in the frame has been updated.
23 MII	MII Interrupt. Indicates that the MII has completed the data transfer requested.
22 EBERR	Ethernet Bus Error Indicates a system bus error occurred when a uDMA transaction is underway. When this bit is set, ECR[ETHEREN] is cleared, halting frame processing by the MAC. When this occurs, software must ensure proper actions, possibly resetting the system, to resume normal operation.
21 LC	Late Collision

Table continues on the next page...

## ENETx\_EIR field descriptions (continued)

Field	Description
	Indicates a collision occurred beyond the collision window (slot time) in half-duplex mode. The frame truncates with a bad CRC and the remainder of the frame is discarded.
20 RL	Collision Retry Limit  Indicates a collision occurred on each of 16 successive attempts to transmit the frame. The frame is discarded without being transmitted and transmission of the next frame commences. This error can only occur in half-duplex mode.
19 UN	Transmit FIFO Underrun  Indicates the transmit FIFO became empty before the complete frame was transmitted.  <b>NOTE:</b> In situations where the device has various masters generating high traffic, a FIFO underrun can occur on the transmit FIFO. To avoid transmit FIFO underrun, store and forward can be enabled in ENET_TFWR[STRFWD]. See STRFWD. Also, a higher priority can be set for ENET traffic using available means on the central bus fabric connecting the ENET module.
18 PLR	Payload Receive Error  Indicates a frame was received with a payload length error. See Frame Length/Type Verification: Payload Length Check for more information.
17 WAKEUP	Node Wakeup Request Indication  Read-only status bit to indicate that a magic packet has been detected. Will act only if ECR[MAGICEN] is set.
16 TS_AVAIL	Transmit Timestamp Available  Indicates that the timestamp of the last transmitted timing frame is available in the ATSTMP register.
15 TS_TIMER	Timestamp Timer  The adjustable timer reached the period event. A period event interrupt can be generated if ATCR[PEREN] is set and the timer wraps according to the periodic setting in the ATPER register. Set the timer period value before setting ATCR[PEREN].
14–13 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
12 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
11–9 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
8 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.

## 40.6.2 Interrupt Mask Register (ENETx\_EIMR)

EIMR controls which interrupt events are allowed to generate actual interrupts. A hardware reset clears this register. If the corresponding bits in the EIR and EIMR registers are set, an interrupt is generated. The interrupt signal remains asserted until a 1 is written to the EIR field (write 1 to clear) or a 0 is written to the EIMR field.

Address: 402D\_4000h base + 8h offset = 402D\_4008h

### ENETx\_EIMR field descriptions

Field	Description
31 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
30 BABR	BABR Interrupt Mask  Corresponds to interrupt source EIR[BABR] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR BABR field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.  0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
29 BABT	BABT Interrupt Mask  Corresponds to interrupt source EIR[BABT] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR BABT field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.  0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
28 GRA	GRA Interrupt Mask  Corresponds to interrupt source EIR[GRA] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The

Field	Description
	<p>corresponding EIR GRA field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.</p> <p>0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.</p>
27 TXF	<p>TXF Interrupt Mask</p> <p>Corresponds to interrupt source EIR[TXF] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR TXF field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.</p> <p>0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.</p>
26 TXB	<p>TXB Interrupt Mask</p> <p>Corresponds to interrupt source EIR[TXB] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR TXF field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.</p> <p>0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.</p>
25 RXF	<p>RXF Interrupt Mask</p> <p>Corresponds to interrupt source EIR[RXF] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR RXF field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.</p>
24 RXB	<p>RXB Interrupt Mask</p> <p>Corresponds to interrupt source EIR[RXB] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR RXB field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.</p>
23 MII	<p>MII Interrupt Mask</p> <p>Corresponds to interrupt source EIR[MII] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR MII field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.</p>
22 EBERR	<p>EBERR Interrupt Mask</p> <p>Corresponds to interrupt source EIR[EBERR] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR EBERR field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.</p>
21 LC	<p>LC Interrupt Mask</p> <p>Corresponds to interrupt source EIR[LC] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR LC field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.</p>

*Table continues on the next page...*

## ENETx\_EIMR field descriptions (continued)

Field	Description
20 RL	RL Interrupt Mask  Corresponds to interrupt source EIR[RL] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR RL field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
19 UN	UN Interrupt Mask  Corresponds to interrupt source EIR[UN] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR UN field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
18 PLR	PLR Interrupt Mask  Corresponds to interrupt source EIR[PLR] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR PLR field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
17 WAKEUP	WAKEUP Interrupt Mask  Corresponds to interrupt source EIR[WAKEUP] register and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR WAKEUP field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
16 TS_AVAIL	TS_AVAIL Interrupt Mask  Corresponds to interrupt source EIR[TS_AVAIL] register and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR TS_AVAIL field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
15 TS_TIMER	TS_TIMER Interrupt Mask  Corresponds to interrupt source EIR[TS_TIMER] register and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR TS_TIMER field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
14–13 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.

11–9 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
8 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.

### 40.6.3 Receive Descriptor Active Register (ENETx\_RDAR)

RDAR is a command register, written by the user, to indicate that the receive descriptor ring has been updated, that is, that the driver produced empty receive buffers with the empty bit set.

Address: 402D\_4000h base + 10h offset = 402D\_4010h

**ENETx\_RDAR field descriptions**

Field	Description
31–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 RDAR	Receive Descriptor Active  Always set to 1 when this register is written, regardless of the value written. This field is cleared by the MAC device when no additional empty descriptors remain in the receive ring. It is also cleared when ECR[ETHEREN] transitions from set to cleared or when ECR[RESET] is set.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

### 40.6.4 Transmit Descriptor Active Register (ENETx\_TDAR)

The TDAR is a command register that the user writes to indicate that the transmit descriptor ring has been updated, that is, that transmit buffers have been produced by the driver with the ready bit set in the buffer descriptor.

The TDAR register is cleared at reset, when ECR[ETHEREN] transitions from set to cleared, or when ECR[RESET] is set.

Address: 402D\_4000h base + 14h offset = 402D\_4014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

**ENETx\_TDAR field descriptions**

Field	Description
31–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 TDAR	Transmit Descriptor Active  Always set to 1 when this register is written, regardless of the value written. This bit is cleared by the MAC device when no additional ready descriptors remain in the transmit ring. Also cleared when ECR[ETHEREN] transitions from set to cleared or when ECR[RESET] is set.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

**40.6.5 Ethernet Control Register (ENETx\_ECR)**

ECR is a read/write user register, though hardware may also alter fields in this register. It controls many of the high level features of the Ethernet MAC, including legacy FEC support through the EN1588 field.

Address: 402D\_4000h base + 24h offset = 402D\_4024h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

## ENETx\_ECR field descriptions

Field	Description
31–18 Reserved	This field is reserved. Always write 0111000000000b to this field.
17–12 Reserved	This field is reserved. Always write 0 to this field.
11 Reserved	This field is reserved. Always write 0 to this field.
10 Reserved	This field is reserved. Always write 0 to this field.
9 Reserved	This field is reserved. Always write 0 to this field.
8 DBSWP	Descriptor Byte Swapping Enable Swaps the byte locations of the buffer descriptors. <b>NOTE:</b> This field must be written to 1 after reset. 0 The buffer descriptor bytes are not swapped to support big-endian devices. 1 The buffer descriptor bytes are swapped to support little-endian devices.
7 Reserved	This field is reserved. Always write 0 to this field.
6 DBGEN	Debug Enable Enables the MAC to enter hardware freeze mode when the device enters debug mode. 0 MAC continues operation in debug mode. 1 MAC enters hardware freeze mode when the processor is in debug mode.
5 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
4 EN1588	EN1588 Enable Enables enhanced functionality of the MAC. 0 Legacy FEC buffer descriptors and functions enabled. 1 Enhanced frame time-stamping functions enabled.
3 SLEEP	Sleep Mode Enable 0 Normal operating mode. 1 Sleep mode.
2 MAGICEN	Magic Packet Detection Enable Enables/disables magic packet detection. <b>NOTE:</b> MAGICEN is relevant only if the SLEEP field is set. If MAGICEN is set, changing the SLEEP field enables/disables sleep mode and magic packet detection. <b>NOTE:</b> EIMR[WAKEUP] must be written to one if Magic packet wakeup is programmed to wake up the chip from low power mode. 0 Magic detection logic disabled. 1 The MAC core detects magic packets and asserts EIR[WAKEUP] when a frame is detected.

Table continues on the next page...

## ENETx\_ECR field descriptions (continued)

Field	Description
1 ETHEREN	<p>Ethernet Enable</p> <p>Enables/disables the Ethernet MAC. When the MAC is disabled, the buffer descriptors for an aborted transmit frame are not updated. The uDMA, buffer descriptor, and FIFO control logic are reset, including the buffer descriptor and FIFO pointers.</p> <p>Hardware clears this field under the following conditions:</p> <ul style="list-style-type: none"> <li>• RESET is set by software</li> <li>• An error condition causes the EBERR field to set.</li> </ul> <p><b>NOTE:</b></p> <ul style="list-style-type: none"> <li>• ETHEREN must be set at the very last step during ENET configuration/setup/initialization, only <i>after</i> all other ENET-related registers have been configured.</li> <li>• If ETHEREN is cleared to 0 by software then next time ETHEREN is set, the EIR interrupts must cleared to 0 due to previous pending interrupts.</li> </ul> <p>0 Reception immediately stops and transmission stops after a bad CRC is appended to any currently transmitted frame.</p> <p>1 MAC is enabled, and reception and transmission are possible.</p>
0 RESET	<p>Ethernet MAC Reset</p> <p>When this field is set, it clears the ETHEREN field.</p>

## 40.6.6 MII Management Frame Register (ENETx\_MMFR)

Writing to MMFR triggers a management frame transaction to the PHY device unless MSCR is programmed to zero.

If MSCR is changed from zero to non-zero during a write to MMFR, an MII frame is generated with the data previously written to the MMFR. This allows MMFR and MSCR to be programmed in either order if MSCR is currently zero.

If the MMFR register is written while frame generation is in progress, the frame contents are altered. Software must use the EIR[MII] interrupt indication to avoid writing to the MMFR register while frame generation is in progress.

Address: 402D\_4000h base + 40h offset = 402D\_4040h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## ENETx\_MMFR field descriptions

Field	Description
31–30 ST	<p>Start Of Frame Delimiter</p> <p>See <a href="#">Table 40-42</a> (Clause 22) or <a href="#">Table 40-44</a> (Clause 45) for correct value.</p>

Table continues on the next page...

**ENETx\_MMFR field descriptions (continued)**

Field	Description
29–28 OP	Operation Code See <a href="#">Table 40-42</a> (Clause 22) or <a href="#">Table 40-44</a> (Clause 45) for correct value.
27–23 PA	PHY Address See <a href="#">Table 40-42</a> (Clause 22) or <a href="#">Table 40-44</a> (Clause 45) for correct value.
22–18 RA	Register Address See <a href="#">Table 40-42</a> (Clause 22) or <a href="#">Table 40-44</a> (Clause 45) for correct value.
17–16 TA	Turn Around This field must be programmed to 10 to generate a valid MII management frame.
DATA	Management Frame Data This is the field for data to be written to or read from the PHY register.

**40.6.7 MII Speed Control Register (ENETx\_MSCR)**

MSCR provides control of the MII clock (MDC pin) frequency and allows a preamble drop on the MII management frame.

The MII\_SPEED field must be programmed with a value to provide an MDC frequency of less than or equal to 2.5 MHz to be compliant with the IEEE 802.3 MII specification. The MII\_SPEED must be set to a non-zero value to source a read or write management frame. After the management frame is complete, the MSCR register may optionally be cleared to turn off MDC. The MDC signal generated has a 50% duty cycle except when MII\_SPEED changes during operation. This change takes effect following a rising or falling edge of MDC.

For example, if the internal module clock (that is, peripheral bus clock) is 25 MHz, programming MII\_SPEED to 0x4 results in an MDC as given in the following equation:

$$\text{MII clock frequency} = 25 \text{ MHz} / ((4 + 1) \times 2) = 2.5 \text{ MHz}$$

The following table shows the optimum values for MII\_SPEED as a function of IPS bus clock frequency.

**Table 40-5. Programming Examples for MSCR**

Internal module clock frequency	MSCR [MII_SPEED]	MDC frequency
25 MHz	0x4	2.50 MHz
33 MHz	0x6	2.36 MHz
40 MHz	0x7	2.50 MHz
50 MHz	0x9	2.50 MHz

*Table continues on the next page...*

**Table 40-5. Programming Examples for MSCR (continued)**

Internal module clock frequency	MSCR [MII_SPEED]	MDC frequency
66 MHz	0xD	2.36 MHz

Address: 402D\_4000h base + 44h offset = 402D\_4044h

Bit	31	30	29	28	27	26	25	24		23	22	21	20	19	18	17	16
R	0																
W																	
Reset	0	0	0	0	0	0	0	0		0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8		7	6	5	4	3	2	1	0
R	0					HOLDTIME			DIS_	MII_SPEED					0		
W									PRE								
Reset	0	0	0	0	0	0	0	0		0	0	0	0	0	0	0	0

**ENETx\_MSCR field descriptions**

Field	Description
31–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–8 HOLDTIME	Hold time On MDIO Output  IEEE802.3 clause 22 defines a minimum of 10 ns for the hold time on the MDIO output. Depending on the host bus frequency, the setting may need to be increased.  000 1 internal module clock cycle 001 2 internal module clock cycles 010 3 internal module clock cycles 111 8 internal module clock cycles
7 DIS_PRE	Disable Preamble  Enables/disables prepending a preamble to the MII management frame. The MII standard allows the preamble to be dropped if the attached PHY devices do not require it.  0 Preamble enabled. 1 Preamble (32 ones) is not prepended to the MII management frame.
6–1 MII_SPEED	MII Speed  Controls the frequency of the MII management interface clock (MDC) relative to the internal module clock. A value of 0 in this field turns off MDC and leaves it in low voltage state. Any non-zero value results in the MDC frequency of:  $1/((\text{MII\_SPEED} + 1) \times 2)$ of the internal module clock frequency
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

### 40.6.8 MIB Control Register (ENETx\_MIBC)

MIBC is a read/write register controlling and observing the state of the MIB block. Access this register to disable the MIB block operation or clear the MIB counters. The MIB\_DIS field resets to 1.

Address: 402D\_4000h base + 64h offset = 402D\_4064h

**ENETx\_MIBC field descriptions**

Field	Description
31 MIB_DIS	Disable MIB Logic If this control field is set, 0 MIB logic is enabled. 1 MIB logic is disabled. The MIB logic halts and does not update any MIB counters.

*Table continues on the next page...*

### ENETx\_MIBC field descriptions (continued)

Field	Description
30 MIB_IDLE	MIB Idle 0 The MIB block is updating MIB counters. 1 The MIB block is not currently updating any MIB counters.
29 MIB_CLEAR	MIB Clear  <b>NOTE:</b> This field is not self-clearing. To clear the MIB counters set and then clear this field. 0 See note above. 1 All statistics counters are reset to 0.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

### 40.6.9 Receive Control Register (ENETx\_RCR)

Address: 402D\_4000h base + 84h offset = 402D\_4084h

## ENETx\_RCR field descriptions

Field	Description
31 GRS	Graceful Receive Stopped Read-only status indicating that the MAC receive datapath is stopped.
30 NLC	Payload Length Check Disable Enables/disables a payload length check. 0 The payload length check is disabled. 1 The core checks the frame's payload length with the frame length/type field. Errors are indicated in the EIR[PLR] field.
29–16 MAX_FL	Maximum Frame Length Resets to decimal 1518. Length is measured starting at DA and includes the CRC at the end of the frame. Transmit frames longer than MAX_FL cause the BABT interrupt to occur. Receive frames longer than MAX_FL cause the BABR interrupt to occur and set the LG field in the end of frame receive buffer descriptor. The recommended default value to be programmed is 1518 or 1522 if VLAN tags are supported.
15 CFEN	MAC Control Frame Enable Enables/disables the MAC control frame. 0 MAC control frames with any opcode other than 0x0001 (pause frame) are accepted and forwarded to the client interface. 1 MAC control frames with any opcode other than 0x0001 (pause frame) are silently discarded.
14 CRCFWD	Terminate/Forward Received CRC Specifies whether the CRC field of received frames is transmitted or stripped. <b>NOTE:</b> If padding function is enabled (PADEN = 1), CRCFWD is ignored and the CRC field is checked and always terminated and removed. 0 The CRC field of received frames is transmitted to the user application. 1 The CRC field is stripped from the frame.
13 PAUFWD	Terminate/Forward Pause Frames Specifies whether pause frames are terminated or forwarded. 0 Pause frames are terminated and discarded in the MAC. 1 Pause frames are forwarded to the user application.
12 PADEN	Enable Frame Padding Remove On Receive Specifies whether the MAC removes padding from received frames. 0 No padding is removed on receive by the MAC. 1 Padding is removed from received frames.
11–10 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
9 RMII_10T	Enables 10-Mbit/s mode of the RMII . 0 100-Mbit/s operation. 1 10-Mbit/s operation.

Table continues on the next page...

**ENETx\_RCR field descriptions (continued)**

Field	Description
8 RMII_MODE	<p>RMII Mode Enable</p> <p>Specifies whether the MAC is configured for MII mode or RMII operation .</p> <p>0 MAC configured for MII mode. 1 MAC configured for RMII operation.</p>
7 Reserved	<p>This field is reserved.</p> <p>This write-only field is reserved. It must always be written with the value 0.</p>
6 Reserved	<p>This field is reserved.</p> <p>This write-only field is reserved. It must always be written with the value 0.</p>
5 FCE	<p>Flow Control Enable</p> <p>If set, the receiver detects PAUSE frames. Upon PAUSE frame detection, the transmitter stops transmitting data frames for a given duration.</p>
4 BC_REJ	<p>Broadcast Frame Reject</p> <p>If set, frames with destination address (DA) equal to 0xFFFF_FFFF_FFFF are rejected unless the PROM field is set. If BC_REJ and PROM are set, frames with broadcast DA are accepted and the MISS (M) is set in the receive buffer descriptor.</p>
3 PROM	<p>Promiscuous Mode</p> <p>All frames are accepted regardless of address matching.</p> <p>0 Disabled. 1 Enabled.</p>
2 MII_MODE	<p>Media Independent Interface Mode</p> <p>This field must always be set.</p> <p>0 Reserved. 1 MII or RMII mode, as indicated by the RMII_MODE field.</p>
1 DRT	<p>Disable Receive On Transmit</p> <p>0 Receive path operates independently of transmit (i.e., full-duplex mode). Can also be used to monitor transmit activity in half-duplex mode. 1 Disable reception of frames while transmitting. (Normally used for half-duplex mode.)</p>
0 LOOP	<p>Internal Loopback</p> <p>This is an MII internal loopback, therefore MII_MODE must be written to 1 and RMII_MODE must be written to 0.</p> <p>0 Loopback disabled. 1 Transmitted frames are looped back internal to the device and transmit MII output signals are not asserted. DRT must be cleared.</p>

### 40.6.10 Transmit Control Register (ENETx\_TCR)

TCR is read/write and configures the transmit block. This register is cleared at system reset. FDEN can only be modified when ECR[ETHEREN] is cleared.

Address: 402D\_4000h base + C4h offset = 402D\_40C4h

ENETx\_TCR field descriptions

Field	Description
31–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 Reserved	This field is reserved. This field is read/write and must be set to 0.
9 CRCFWD	Forward Frame From Application With CRC

Table continues on the next page...

## ENETx\_TCR field descriptions (continued)

Field	Description
	<p>0 TxBD[TC] controls whether the frame has a CRC from the application.</p> <p>1 The transmitter does not append any CRC to transmitted frames, as it is expecting a frame with CRC from the application.</p>
8 ADDINS	<p>Set MAC Address On Transmit</p> <p>0 The source MAC address is not modified by the MAC.</p> <p>1 The MAC overwrites the source MAC address with the programmed MAC address according to ADDSEL.</p>
7–5 ADDSEL	<p>Source MAC Address Select On Transmit</p> <p>If ADDINS is set, indicates the MAC address that overwrites the source MAC address.</p> <p>000 Node MAC address programmed on PADDR1/2 registers.</p> <p>100 Reserved.</p> <p>101 Reserved.</p> <p>110 Reserved.</p>
4 RFC_PAUSE	<p>Receive Frame Control Pause</p> <p>This status field is set when a full-duplex flow control pause frame is received and the transmitter pauses for the duration defined in this pause frame. This field automatically clears when the pause duration is complete.</p>
3 TFC_PAUSE	<p>Transmit Frame Control Pause</p> <p>Pauses frame transmission. When this field is set, EIR[GRA] is set. With transmission of data frames stopped, the MAC transmits a MAC control PAUSE frame. Next, the MAC clears TFC_PAUSE and resumes transmitting data frames. If the transmitter pauses due to user assertion of GTS or reception of a PAUSE frame, the MAC may continue transmitting a MAC control PAUSE frame.</p> <p>0 No PAUSE frame transmitted.</p> <p>1 The MAC stops transmission of data frames after the current transmission is complete.</p>
2 FDEN	<p>Full-Duplex Enable</p> <p>If this field is set, frames transmit independent of carrier sense and collision inputs. Only modify this bit when ECR[ETHEREN] is cleared.</p>
1 Reserved	<p>This field is reserved.</p> <p>This write-only field is reserved. It must always be written with the value 0.</p>
0 GTS	<p>Graceful Transmit Stop</p> <p>When this field is set, MAC stops transmission after any frame currently transmitted is complete and EIR[GRA] is set. If frame transmission is not currently underway, the GRA interrupt is asserted immediately. After transmission finishes, clear GTS to restart. The next frame in the transmit FIFO is then transmitted. If an early collision occurs during transmission when GTS is set, transmission stops after the collision. The frame is transmitted again after GTS is cleared. There may be old frames in the transmit FIFO that transmit when GTS is reasserted. To avoid this, clear ECR[ETHEREN] following the GRA interrupt.</p>

### 40.6.11 Physical Address Lower Register (ENETx\_PALR)

PALR contains the lower 32 bits (bytes 0, 1, 2, 3) of the 48-bit address used in the address recognition process to compare with the destination address (DA) field of receive frames with an individual DA. In addition, this register is used in bytes 0 through 3 of the six-byte source address field when transmitting PAUSE frames.

Address: 402D\_4000h base + E4h offset = 402D\_40E4h

#### ENETx\_PALR field descriptions

Field	Description
PADDR1	Pause Address  Bytes 0 (bits 31:24), 1 (bits 23:16), 2 (bits 15:8), and 3 (bits 7:0) of the 6-byte individual address are used for exact match and the source address field in PAUSE frames.

### 40.6.12 Physical Address Upper Register (ENETx\_PAUR)

PAUR contains the upper 16 bits (bytes 4 and 5) of the 48-bit address used in the address recognition process to compare with the destination address (DA) field of receive frames with an individual DA. In addition, this register is used in bytes 4 and 5 of the six-byte source address field when transmitting PAUSE frames. Bits 15:0 of PAUR contain a constant type field (0x8808) for transmission of PAUSE frames.

Address: 402D\_4000h base + E8h offset = 402D\_40E8h

#### ENETx\_PAUR field descriptions

Field	Description
31–16 PADDR2	Bytes 4 (bits 31:24) and 5 (bits 23:16) of the 6-byte individual address used for exact match, and the source address field in PAUSE frames.
TYPE	Type Field In PAUSE Frames  These fields have a constant value of 0x8808.

### 40.6.13 Opcode/Pause Duration Register (ENETx\_OPD)

OPD is read/write accessible. This register contains the 16-bit opcode and 16-bit pause duration fields used in transmission of a PAUSE frame. The opcode field is a constant value, 0x0001. When another node detects a PAUSE frame, that node pauses transmission for the duration specified in the pause duration field. The lower 16 bits of this register are not reset and you must initialize it.

Address: 402D\_4000h base + ECh offset = 402D\_40ECh

#### ENETx\_OPD field descriptions

Field	Description
31–16 OPCODE	Opcode Field In PAUSE Frames These fields have a constant value of 0x0001.
PAUSE_DUR	Pause Duration Pause duration field used in PAUSE frames.

### 40.6.14 Transmit Interrupt Coalescing Register (ENETx\_TXIC)

See [Interrupt coalescence](#) for more information.

Address: 402D\_4000h base + F0h offset = 402D\_40F0h

#### ENETx\_TXIC field descriptions

Field	Description
31 ICEN	Interrupt Coalescing Enable

Table continues on the next page...

**ENETx\_TXIC field descriptions (continued)**

Field	Description
	0 Disable Interrupt coalescing. 1 Enable Interrupt coalescing.
30 ICCS	Interrupt Coalescing Timer Clock Source Select  0 Use MII/GMII TX clocks. 1 Use ENET system clock.
29–28 Reserved	This field must be set to 0.  This field is reserved.
27–20 ICFT	Interrupt coalescing frame count threshold  This value determines the number of frames needed to be transmitted for raising an interrupt. Frame counter restarts after reaching this threshold value or after the expiring of the coalescing timer. Must be greater than zero to avoid unpredictable behavior.
19–16 Reserved	This field must be set to 0.  This field is reserved.
ICTT	Interrupt coalescing timer threshold  Interrupt coalescing timer threshold in units of 64 clock periods. This value determines the maximum amount of time after transmitting a frame before raising an interrupt. The threshold timer is disabled after expiring or number of frame transmission defined by ICFT and starts again upon transmission of the next first frame. Must be greater than zero to avoid unpredictable behavior.

**40.6.15 Receive Interrupt Coalescing Register (ENETx\_RXIC)**

See [Interrupt coalescence](#) for more information.

Address: 402D\_4000h base + 100h offset = 402D\_4100h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R																
W	ICEN	ICCS	Reserved			ICFT						Reserved				
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																
W	ICTT															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**ENETx\_RXIC field descriptions**

Field	Description
31 ICEN	Interrupt Coalescing Enable  0 Disable Interrupt coalescing. 1 Enable Interrupt coalescing.

*Table continues on the next page...*

**ENETx\_RXIC field descriptions (continued)**

Field	Description
30 ICCS	Interrupt Coalescing Timer Clock Source Select  0 Use MII/GMII TX clocks. 1 Use ENET system clock.
29–28 Reserved	This field must be set to 0.  This field is reserved.
27–20 ICFT	Interrupt coalescing frame count threshold  This value determines the number of frames needed to be received for raising an interrupt. Frame counter restarts after reaching this threshold value or after the expiring of the coalescing timer. Must be greater than zero to avoid unpredictable behavior.
19–16 Reserved	This field must be set to 0.  This field is reserved.
ICTT	Interrupt coalescing timer threshold  Interrupt coalescing timer threshold in units of 64 clock periods. This value determines the maximum amount of time after receiving a frame before raising an interrupt. The threshold timer is disabled after expiring or number of frame reception defined by ICFT and starts again upon reception of the next first frame. Must be greater than zero to avoid unpredictable behavior.

**40.6.16 Descriptor Individual Upper Address Register (ENETx\_IAUR)**

IAUR contains the upper 32 bits of the 64-bit individual address hash table. The address recognition process uses this table to check for a possible match with the destination address (DA) field of receive frames with an individual DA. This register is not reset and you must initialize it.

Address: 402D\_4000h base + 118h offset = 402D\_4118h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																																
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**ENETx\_IAUR field descriptions**

Field	Description
IADDR1	Contains the upper 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a unicast address. Bit 31 of IADDR1 contains hash index bit 63. Bit 0 of IADDR1 contains hash index bit 32.

### 40.6.17 Descriptor Individual Lower Address Register (ENETx\_IALR)

IALR contains the lower 32 bits of the 64-bit individual address hash table. The address recognition process uses this table to check for a possible match with the DA field of receive frames with an individual DA. This register is not reset and you must initialize it.

Address: 402D\_4000h base + 11Ch offset = 402D\_411Ch

#### ENETx\_IALR field descriptions

Field	Description
IADDR2	Contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a unicast address. Bit 31 of IADDR2 contains hash index bit 31. Bit 0 of IADDR2 contains hash index bit 0.

### 40.6.18 Descriptor Group Upper Address Register (ENETx\_GAUR)

GAUR contains the upper 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. You must initialize this register.

Address: 402D\_4000h base + 120h offset = 402D\_4120h

#### ENETx\_GAUR field descriptions

Field	Description
GADDR1	Contains the upper 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. Bit 31 of GADDR1 contains hash index bit 63. Bit 0 of GADDR1 contains hash index bit 32.

### 40.6.19 Descriptor Group Lower Address Register (ENETx\_GALR)

GALR contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. You must initialize this register.

Address: 402D\_4000h base + 124h offset = 402D\_4124h

#### ENETx\_GALR field descriptions

Field	Description
GADDR2	Contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. Bit 31 of GADDR2 contains hash index bit 31. Bit 0 of GADDR2 contains hash index bit 0.

### 40.6.20 Transmit FIFO Watermark Register (ENETx\_TFWR)

If TFWR[STRFWD] is cleared, TFWR[TFWR] controls the amount of data required in the transmit FIFO before transmission of a frame can begin. This allows you to minimize transmit latency (TFWR = 00 or 01) or allow for larger bus access latency (TFWR = 11) due to contention for the system bus. Setting the watermark to a high value minimizes the risk of transmit FIFO underrun due to contention for the system bus. The byte counts associated with the TFWR field may need to be modified to match a given system requirement, for example, worst-case bus access latency by the transmit data uDMA channel.

When the FIFO level reaches the value the TFWR field and when the STR\_FWD is set to '0', the MAC transmit control logic starts frame transmission even before the end-of-frame is available in the FIFO (cut-through operation).

If a complete frame has a size smaller than the threshold programmed with TFWR, the MAC also transmits the Frame to the line.

To enable store and forward on the Transmit path, set STR\_FWD to '1'. In this case, the MAC starts to transmit data only when a complete frame is stored in the Transmit FIFO.

## Memory map/register definition

Address: 402D\_4000h base + 144h offset = 402D\_4144h

### ENETx\_TFWR field descriptions

Field	Description
31–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 STRFWD	Store And Forward Enable  0 Reset. The transmission start threshold is programmed in TFWR[TFWR]. 1 Enabled.
7–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TFWR	Transmit FIFO Write  If TFWR[STRFWD] is cleared, this field indicates the number of bytes, in steps of 64 bytes, written to the transmit FIFO before transmission of a frame begins.  <b>NOTE:</b> If a frame with less than the threshold is written, it is still sent independently of this threshold setting. The threshold is relevant only if the frame is larger than the threshold given.  000000 64 bytes written. 000001 64 bytes written. 000010 128 bytes written. 000011 192 bytes written. ... .. 011111 1984 bytes written.

## 40.6.21 Receive Descriptor Ring Start Register (ENETx\_RDSR)

RDSR points to the beginning of the circular receive buffer descriptor queue in external memory. This pointer must be 64-bit aligned (bits 2–0 must be zero); however, for optimal performance the pointer should be 512-bit aligned, that is, evenly divisible by 64.

### NOTE

This register must be initialized prior to operation

Address: 402D\_4000h base + 180h offset = 402D\_4180h

Bit	31	30	29	28	27	26	25	24		23	22	21	20	19	18	17	16
R	R_DES_START																
W																	
Reset	0	0	0	0	0	0	0	0		0	0	0	0	0	0	0	0

R	R_DES_START															0	
W															0		
Reset	0	0	0	0	0	0	0	0		0	0	0	0	0	0	0	0

**ENETx\_RDSR field descriptions**

Field	Description
31–3 R_DES_START	Pointer to the beginning of the receive buffer descriptor queue.
2 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

### 40.6.22 Transmit Buffer Descriptor Ring Start Register (ENETx\_TDSR)

TDSR provides a pointer to the beginning of the circular transmit buffer descriptor queue in external memory. This pointer must be 64-bit aligned (bits 2–0 must be zero); however, for optimal performance the pointer should be 512-bit aligned, that is, evenly divisible by 64.

**NOTE**

This register must be initialized prior to operation.

Address: 402D\_4000h base + 184h offset = 402D\_4184h

Bit	31	30	29	28	27	26	25	24		23	22	21	20	19	18	17	16
R	X_DES_START																
W

Bit	15	14	13	12	11	10	9	8		7	6	5	4	3	2	1	0
R	X_DES_START															0	
W															0		
Reset	0	0	0	0	0	0	0	0		0	0	0	0	0	0	0	0

### ENETx\_TDSR field descriptions

Field	Description
31–3 X_DES_START	Pointer to the beginning of the transmit buffer descriptor queue.
2 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

### 40.6.23 Maximum Receive Buffer Size Register (ENETx\_MRBR)

The MRBR is a user-programmable register that dictates the maximum size of all receive buffers. This value should take into consideration that the receive CRC is always written into the last receive buffer.

- R\_BUF\_SIZE is concatenated with the four least-significant bits of this register and are used as the maximum receive buffer size.
- To allow one maximum size frame per buffer, MRBR must be set to RCR[MAX\_FL] or larger.
- To properly align the buffer, MRBR must be evenly divisible by 64. To ensure this, set the lower two bits of R\_BUF\_SIZE to zero. The lower four bits of this register are already set to zero by the device.
- To minimize bus usage (descriptor fetches), set MRBR greater than or equal to 256 bytes.

#### NOTE

This register must be initialized before operation.

Address: 402D\_4000h base + 188h offset = 402D\_4188h

### ENETx\_MRBR field descriptions

Field	Description
31–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–4 R_BUF_SIZE	Receive buffer size in bytes. This value, concatenated with the four least-significant bits of this register (which are always zero), is the effective maximum receive buffer size.
Reserved	This field, which is always zero, is the four least-significant bits of the maximum receive buffer size.  This field is reserved. This read-only field is reserved and always has the value 0.

## 40.6.24 Receive FIFO Section Full Threshold (ENETx\_RSFL)

Address: 402D\_4000h base + 190h offset = 402D\_4190h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																RX_SECTION_FULL															
W	0																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### ENETx\_RSFL field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
RX_SECTION_FULL	Value Of Receive FIFO Section Full Threshold  Value, in 64-bit words, of the receive FIFO section full threshold. Clear this field to enable store and forward on the RX FIFO. When programming a value greater than 0 (cut-through operation), it must be greater than RAEM[RX_ALMOST_EMPTY].  When the FIFO level reaches the value in this field, data is available in the Receive FIFO (cut-through operation).

## 40.6.25 Receive FIFO Section Empty Threshold (ENETx\_RSEM)

Address: 402D\_4000h base + 194h offset = 402D\_4194h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0												STAT_SECTION_EMPTY				0				RX_SECTION_EMPTY											
W	0																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### ENETx\_RSEM field descriptions

Field	Description
31–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–16 STAT_SECTION_EMPTY	RX Status FIFO Section Empty Threshold  Defines number of frames in the receive FIFO, independent of its size, that can be accepted. If the limit is reached, reception will continue normally, however a pause frame will be triggered to indicate a possible congestion to the remote device to avoid FIFO overflow. A value of 0 disables automatic pause frame generation
15–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
RX_SECTION_EMPTY	Value Of The Receive FIFO Section Empty Threshold  Value, in 64-bit words, of the receive FIFO section empty threshold. When the FIFO has reached this level, a pause frame will be issued.

Table continues on the next page...

**ENETx\_RSEM field descriptions (continued)**

Field	Description
	<p>A value of 0 disables automatic pause frame generation.</p> <p>When the FIFO level goes below the value programmed in this field, an XON pause frame is issued to indicate the FIFO congestion is cleared to the remote Ethernet client.</p> <p><b>NOTE:</b> The section-empty threshold indications from both FIFOs are OR'ed to cause XOFF pause frame generation.</p>

**40.6.26 Receive FIFO Almost Empty Threshold (ENETx\_RAEM)**

Address: 402D\_4000h base + 198h offset = 402D\_4198h

**ENETx\_RAEM field descriptions**

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
RX_ALMOST_EMPTY	Value Of The Receive FIFO Almost Empty Threshold  Value, in 64-bit words, of the receive FIFO almost empty threshold. When the FIFO level reaches the value programmed in this field and the end-of-frame has not been received for the frame yet, the core receive read control stops FIFO read (and subsequently stops transferring data to the MAC client application). It continues to deliver the frame, if again more data than the threshold or the end-of-frame is available in the FIFO. A minimum value of 4 should be set.

**40.6.27 Receive FIFO Almost Full Threshold (ENETx\_RAFL)**

Address: 402D\_4000h base + 19Ch offset = 402D\_419Ch

**ENETx\_RAFL field descriptions**

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
RX_ALMOST_FULL	Value Of The Receive FIFO Almost Full Threshold

Table continues on the next page...

## ENETx\_RAFL field descriptions (continued)

Field	Description
	Value, in 64-bit words, of the receive FIFO almost full threshold. When the FIFO level comes close to the maximum, so that there is no more space for at least RX_ALMOST_FULL number of words, the MAC stops writing data in the FIFO and truncates the received frame to avoid FIFO overflow. The corresponding error status will be set when the frame is delivered to the application. A minimum value of 4 should be set.

## 40.6.28 Transmit FIFO Section Empty Threshold (ENETx\_TSEM)

Address: 402D\_4000h base + 1A0h offset = 402D\_41A0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																TX_SECTION_EMPTY															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

## ENETx\_TSEM field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TX_SECTION_EMPTY	Value Of The Transmit FIFO Section Empty Threshold Value, in 64-bit words, of the transmit FIFO section empty threshold. See <a href="#">Transmit FIFO</a> for more information.

## 40.6.29 Transmit FIFO Almost Empty Threshold (ENETx\_TAEM)

Address: 402D\_4000h base + 1A4h offset = 402D\_41A4h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																TX_ALMOST_EMPTY															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0

## ENETx\_TAEM field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TX_ALMOST_EMPTY	Value of Transmit FIFO Almost Empty Threshold Value, in 64-bit words, of the transmit FIFO almost empty threshold. When the FIFO level reaches the value programmed in this field, and no end-of-frame is available for the frame, the MAC transmit logic, to avoid FIFO underflow, stops reading the FIFO and transmits a frame with an MII error indication. See <a href="#">Transmit FIFO</a> for more information. A minimum value of 4 should be set.

### 40.6.30 Transmit FIFO Almost Full Threshold (ENETx\_TAFL)

Address: 402D\_4000h base + 1A8h offset = 402D\_41A8h

#### ENETx\_TAFL field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TX_ALMOST_FULL	Value Of The Transmit FIFO Almost Full Threshold  Value, in 64-bit words, of the transmit FIFO almost full threshold. A minimum value of six is required . A recommended value of at least 8 should be set allowing a latency of two clock cycles to the application. If more latency is required the value can be increased as necessary (latency = TAFL - 5).  When the FIFO level comes close to the maximum, so that there is no more space for at least TX_ALMOST_FULL number of words, the pin ff_tx_rdy is deasserted. If the application does not react on this signal, the FIFO write control logic, to avoid FIFO overflow, truncates the current frame and sets the error status. As a result, the frame will be transmitted with an GMII/MII error indication. See <a href="#">Transmit FIFO</a> for more information.  <b>NOTE:</b> A FIFO overflow is a fatal error and requires a global reset on the transmit datapath or at least deassertion of ETHEREN.

### 40.6.31 Transmit Inter-Packet Gap (ENETx\_TIPG)

Address: 402D\_4000h base + 1ACh offset = 402D\_41ACh

#### ENETx\_TIPG field descriptions

Field	Description
31–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
IPG	Transmit Inter-Packet Gap  Indicates the IPG, in bytes, between transmitted frames. Valid values range from 8 to 26. If the written value is less than 8 or greater than 26, the internal (effective) IPG is 12.  <b>NOTE:</b> The IPG value read will be the value that was written, even if it is out of range.

### 40.6.32 Frame Truncation Length (ENETx\_FTRL)

Address: 402D\_4000h base + 1B0h offset = 402D\_41B0h

#### ENETx\_FTRL field descriptions

Field	Description
31–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TRUNC_FL	Frame Truncation Length  Indicates the value a receive frame is truncated, if it is greater than this value. Must be greater than or equal to RCR[MAX_FL].  <b>NOTE:</b> Truncation happens at TRUNC_FL. However, when truncation occurs, the application (FIFO) may receive less data, guaranteeing that it never receives more than the set limit.

### 40.6.33 Transmit Accelerator Function Configuration (ENETx\_TACC)

TACC controls accelerator actions when sending frames. The register can be changed before or after each frame, but it must remain unmodified during frame writes into the transmit FIFO.

The TFWR[STRFWD] field must be set to use the checksum feature.

Address: 402D\_4000h base + 1C0h offset = 402D\_41C0h

### ENETx\_TACC field descriptions

Field	Description
31–5 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
4 PROCHK	Enables insertion of protocol checksum. 0 Checksum not inserted. 1 If an IP frame with a known protocol is transmitted, the checksum is inserted automatically into the frame. The checksum field must be cleared. The other frames are not modified.
3 IPCHK	Enables insertion of IP header checksum. 0 Checksum is not inserted. 1 If an IP frame is transmitted, the checksum is inserted automatically. The IP header checksum field must be cleared. If a non-IP frame is transmitted the frame is not modified.
2–1 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
0 SHIFT16	TX FIFO Shift-16 0 Disabled. 1 Indicates to the transmit data FIFO that the written frames contain two additional octets before the frame data. This means the actual frame begins at bit 16 of the first word written into the FIFO. This function allows putting the frame payload on a 32-bit boundary in memory, as the 14-byte Ethernet header is extended to a 16-byte header.

### 40.6.34 Receive Accelerator Function Configuration (ENETx\_RACC)

Address: 402D\_4000h base + 1C4h offset = 402D\_41C4h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	[Reserved]															
W	0															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	[Reserved]								SHIFT16	LINEDIS	[Reserved]			PRODIS	IPDIS	PADREM
W	0								SHIFT16	LINEDIS	0			PRODIS	IPDIS	PADREM
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### ENETx\_RACC field descriptions

Field	Description
31–8 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.

Table continues on the next page...

## ENETx\_RACC field descriptions (continued)

Field	Description
7 SHIFT16	<p>RX FIFO Shift-16</p> <p>When this field is set, the actual frame data starts at bit 16 of the first word read from the RX FIFO aligning the Ethernet payload on a 32-bit boundary.</p> <p><b>NOTE:</b> This function only affects the FIFO storage and has no influence on the statistics, which use the actual length of the frame received.</p> <p>0 Disabled. 1 Instructs the MAC to write two additional bytes in front of each frame received into the RX FIFO.</p>
6 LINEDIS	<p>Enable Discard Of Frames With MAC Layer Errors</p> <p>0 Frames with errors are not discarded. 1 Any frame received with a CRC, length, or PHY error is automatically discarded and not forwarded to the user application interface.</p>
5–3 Reserved	<p>This field is reserved. This write-only field is reserved. It must always be written with the value 0.</p>
2 PRODIS	<p>Enable Discard Of Frames With Wrong Protocol Checksum</p> <p>0 Frames with wrong checksum are not discarded. 1 If a TCP/IP, UDP/IP, or ICMP/IP frame is received that has a wrong TCP, UDP, or ICMP checksum, the frame is discarded. Discarding is only available when the RX FIFO operates in store and forward mode (RSFL cleared).</p>
1 IPDIS	<p>Enable Discard Of Frames With Wrong IPv4 Header Checksum</p> <p>0 Frames with wrong IPv4 header checksum are not discarded. 1 If an IPv4 frame is received with a mismatching header checksum, the frame is discarded. IPv6 has no header checksum and is not affected by this setting. Discarding is only available when the RX FIFO operates in store and forward mode (RSFL cleared).</p>
0 PADREM	<p>Enable Padding Removal For Short IP Frames</p> <p>0 Padding not removed. 1 Any bytes following the IP payload section of the frame are removed from the frame.</p>

## 40.6.35 Reserved Statistic Register (ENETx\_RMON\_T\_DROP)

Address: 402D\_4000h base + 200h offset = 402D\_4200h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

## ENETx\_RMON\_T\_DROP field descriptions

Field	Description
Reserved	<p>This read-only field always has the value 0.</p> <p>This field is reserved.</p>

### 40.6.36 Tx Packet Count Statistic Register (ENETx\_RMON\_T\_PACKETS)

Address: 402D\_4000h base + 204h offset = 402D\_4204h

#### ENETx\_RMON\_T\_PACKETS field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TXPKTS	Packet count Transmit packet count

### 40.6.37 Tx Broadcast Packets Statistic Register (ENETx\_RMON\_T\_BC\_PKT)

RMON Tx Broadcast Packets

Address: 402D\_4000h base + 208h offset = 402D\_4208h

#### ENETx\_RMON\_T\_BC\_PKT field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TXPKTS	Broadcast packets

### 40.6.38 Tx Multicast Packets Statistic Register (ENETx\_RMON\_T\_MC\_PKT)

Address: 402D\_4000h base + 20Ch offset = 402D\_420Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0																
R	0																TXPKTS																															
W	[Shaded]																																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ENETx\_RMON\_T\_MC\_PKT field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TXPKTS	Multicast packets

### 40.6.39 Tx Packets with CRC/Align Error Statistic Register (ENETx\_RMON\_T\_CRC\_ALIGN)

Address: 402D\_4000h base + 210h offset = 402D\_4210h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0																
R	0																TXPKTS																															
W	[Shaded]																																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ENETx\_RMON\_T\_CRC\_ALIGN field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TXPKTS	Packets with CRC/align error

### 40.6.40 Tx Packets Less Than Bytes and Good CRC Statistic Register (ENETx\_RMON\_T\_UNDERSIZE)

Address: 402D\_4000h base + 214h offset = 402D\_4214h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0																
R	0																TXPKTS																															
W	[Shaded]																																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**ENETx\_RMON\_T\_UNDERSIZE field descriptions**

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TXPKTS	Number of transmit packets less than 64 bytes with good CRC

**40.6.41 Tx Packets GT MAX\_FL bytes and Good CRC Statistic Register (ENETx\_RMON\_T\_OVERSIZE)**

Address: 402D\_4000h base + 218h offset = 402D\_4218h

**ENETx\_RMON\_T\_OVERSIZE field descriptions**

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TXPKTS	Number of transmit packets greater than MAX_FL bytes with good CRC

**40.6.42 Tx Packets Less Than 64 Bytes and Bad CRC Statistic Register (ENETx\_RMON\_T\_FRAG)**

Address: 402D\_4000h base + 21Ch offset = 402D\_421Ch

**ENETx\_RMON\_T\_FRAG field descriptions**

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TXPKTS	Number of packets less than 64 bytes with bad CRC

### 40.6.43 Tx Packets Greater Than MAX\_FL bytes and Bad CRC Statistic Register (ENETx\_RMON\_T\_JAB)

Address: 402D\_4000h base + 220h offset = 402D\_4220h

ENETx\_RMON\_T\_JAB field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TXPKTS	Number of transmit packets greater than MAX_FL bytes and bad CRC

### 40.6.44 Tx Collision Count Statistic Register (ENETx\_RMON\_T\_COL)

Address: 402D\_4000h base + 224h offset = 402D\_4224h

ENETx\_RMON\_T\_COL field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TXPKTS	Number of transmit collisions

### 40.6.45 Tx 64-Byte Packets Statistic Register (ENETx\_RMON\_T\_P64)

Address: 402D\_4000h base + 228h offset = 402D\_4228h

**ENETx\_RMON\_T\_P64 field descriptions**

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TXPKTS	Number of 64-byte transmit packets

**40.6.46 Tx 65- to 127-byte Packets Statistic Register (ENETx\_RMON\_T\_P65TO127)**

Address: 402D\_4000h base + 22Ch offset = 402D\_422Ch

**ENETx\_RMON\_T\_P65TO127 field descriptions**

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TXPKTS	Number of 65- to 127-byte transmit packets

**40.6.47 Tx 128- to 255-byte Packets Statistic Register (ENETx\_RMON\_T\_P128TO255)**

Address: 402D\_4000h base + 230h offset = 402D\_4230h

**ENETx\_RMON\_T\_P128TO255 field descriptions**

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TXPKTS	Number of 128- to 255-byte transmit packets

### 40.6.48 Tx 256- to 511-byte Packets Statistic Register (ENETx\_RMON\_T\_P256TO511)

Address: 402D\_4000h base + 234h offset = 402D\_4234h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0					
R	0																TXPKTS																				
W	[Shaded]																																				
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ENETx\_RMON\_T\_P256TO511 field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TXPKTS	Number of 256- to 511-byte transmit packets

### 40.6.49 Tx 512- to 1023-byte Packets Statistic Register (ENETx\_RMON\_T\_P512TO1023)

Address: 402D\_4000h base + 238h offset = 402D\_4238h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0						
R	0																TXPKTS																					
W	[Shaded]																																					
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ENETx\_RMON\_T\_P512TO1023 field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TXPKTS	Number of 512- to 1023-byte transmit packets

### 40.6.50 Tx 1024- to 2047-byte Packets Statistic Register (ENETx\_RMON\_T\_P1024TO2047)

Address: 402D\_4000h base + 23Ch offset = 402D\_423Ch

#### ENETx\_RMON\_T\_P1024TO2047 field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TXPKTS	Number of 1024- to 2047-byte transmit packets

### 40.6.51 Tx Packets Greater Than 2048 Bytes Statistic Register (ENETx\_RMON\_T\_P\_GTE2048)

Address: 402D\_4000h base + 240h offset = 402D\_4240h

#### ENETx\_RMON\_T\_P\_GTE2048 field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TXPKTS	Number of transmit packets greater than 2048 bytes

### 40.6.52 Tx Octets Statistic Register (ENETx\_RMON\_T\_OCTETS)

Address: 402D\_4000h base + 244h offset = 402D\_4244h

**ENETx\_RMON\_T\_OCTETS field descriptions**

Field	Description
TXOCTS	Number of transmit octets

**40.6.53 Reserved Statistic Register (ENETx\_IEEE\_T\_DROP)**

Address: 402D\_4000h base + 248h offset = 402D\_4248h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0					
R	Reserved																																				
W																																					
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**ENETx\_IEEE\_T\_DROP field descriptions**

Field	Description
Reserved	This read-only field always has the value 0. This field is reserved.

**40.6.54 Frames Transmitted OK Statistic Register (ENETx\_IEEE\_T\_FRAME\_OK)**

Address: 402D\_4000h base + 24Ch offset = 402D\_424Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0					
R	0																	COUNT																			
W																																					
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**ENETx\_IEEE\_T\_FRAME\_OK field descriptions**

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Number of frames transmitted OK  <b>NOTE:</b> Does not increment for the broadcast frames when broadcast reject is enabled and promiscuous mode is disabled within the receive control register (RCR).

### 40.6.55 Frames Transmitted with Single Collision Statistic Register (ENETx\_IEEE\_T\_1COL)

Address: 402D\_4000h base + 250h offset = 402D\_4250h

ENETx\_IEEE\_T\_1COL field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Number of frames transmitted with one collision

### 40.6.56 Frames Transmitted with Multiple Collisions Statistic Register (ENETx\_IEEE\_T\_MCOL)

Address: 402D\_4000h base + 254h offset = 402D\_4254h

ENETx\_IEEE\_T\_MCOL field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Number of frames transmitted with multiple collisions

### 40.6.57 Frames Transmitted after Deferral Delay Statistic Register (ENETx\_IEEE\_T\_DEF)

Address: 402D\_4000h base + 258h offset = 402D\_4258h

**ENETx\_IEEE\_T\_DEF field descriptions**

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Number of frames transmitted with deferral delay

**40.6.58 Frames Transmitted with Late Collision Statistic Register (ENETx\_IEEE\_T\_LCOL)**

Address: 402D\_4000h base + 25Ch offset = 402D\_425Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																COUNT															
W	[Shaded]																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**ENETx\_IEEE\_T\_LCOL field descriptions**

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Number of frames transmitted with late collision

**40.6.59 Frames Transmitted with Excessive Collisions Statistic Register (ENETx\_IEEE\_T\_EXCOL)**

Address: 402D\_4000h base + 260h offset = 402D\_4260h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																COUNT															
W	[Shaded]																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**ENETx\_IEEE\_T\_EXCOL field descriptions**

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Number of frames transmitted with excessive collisions

### 40.6.60 Frames Transmitted with Tx FIFO Underrun Statistic Register (ENETx\_IEEE\_T\_MACERR)

Address: 402D\_4000h base + 264h offset = 402D\_4264h

#### ENETx\_IEEE\_T\_MACERR field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Number of frames transmitted with transmit FIFO underrun

### 40.6.61 Frames Transmitted with Carrier Sense Error Statistic Register (ENETx\_IEEE\_T\_CSERR)

Address: 402D\_4000h base + 268h offset = 402D\_4268h

#### ENETx\_IEEE\_T\_CSERR field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Number of frames transmitted with carrier sense error

### 40.6.62 Reserved Statistic Register (ENETx\_IEEE\_T\_SQE)

Address: 402D\_4000h base + 26Ch offset = 402D\_426Ch

### ENETx\_IEEE\_T\_SQE field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	This read-only field is reserved and always has the value 0.  <b>NOTE:</b> Counter not implemented as no SQE information is available.

### 40.6.63 Flow Control Pause Frames Transmitted Statistic Register (ENETx\_IEEE\_T\_FDXFC)

Address: 402D\_4000h base + 270h offset = 402D\_4270h

### ENETx\_IEEE\_T\_FDXFC field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Number of flow-control pause frames transmitted

### 40.6.64 Octet Count for Frames Transmitted w/o Error Statistic Register (ENETx\_IEEE\_T\_OCTETS\_OK)

Address: 402D\_4000h base + 274h offset = 402D\_4274h

### ENETx\_IEEE\_T\_OCTETS\_OK field descriptions

Field	Description
COUNT	Octet count for frames transmitted without error  <b>NOTE</b> Counts total octets (includes header and FCS fields).

### 40.6.65 Rx Packet Count Statistic Register (ENETx\_RMON\_R\_PACKETS)

Address: 402D\_4000h base + 284h offset = 402D\_4284h

#### ENETx\_RMON\_R\_PACKETS field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Number of packets received

### 40.6.66 Rx Broadcast Packets Statistic Register (ENETx\_RMON\_R\_BC\_PKT)

Address: 402D\_4000h base + 288h offset = 402D\_4288h

#### ENETx\_RMON\_R\_BC\_PKT field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Number of receive broadcast packets

### 40.6.67 Rx Multicast Packets Statistic Register (ENETx\_RMON\_R\_MC\_PKT)

Address: 402D\_4000h base + 28Ch offset = 402D\_428Ch

**ENETx\_RMON\_R\_MC\_PKT field descriptions**

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Number of receive multicast packets

**40.6.68 Rx Packets with CRC/Align Error Statistic Register (ENETx\_RMON\_R\_CRC\_ALIGN)**

Address: 402D\_4000h base + 290h offset = 402D\_4290h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																COUNT															
W	[Shaded]																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**ENETx\_RMON\_R\_CRC\_ALIGN field descriptions**

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Number of receive packets with CRC or align error

**40.6.69 Rx Packets with Less Than 64 Bytes and Good CRC Statistic Register (ENETx\_RMON\_R\_UNDERSIZE)**

Address: 402D\_4000h base + 294h offset = 402D\_4294h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																COUNT															
W	[Shaded]

**ENETx\_RMON\_R\_UNDERSIZE field descriptions**

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Number of receive packets with less than 64 bytes and good CRC

### 40.6.70 Rx Packets Greater Than MAX\_FL and Good CRC Statistic Register (ENETx\_RMON\_R\_OVERSIZE)

Address: 402D\_4000h base + 298h offset = 402D\_4298h

#### ENETx\_RMON\_R\_OVERSIZE field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Number of receive packets greater than MAX_FL and good CRC

### 40.6.71 Rx Packets Less Than 64 Bytes and Bad CRC Statistic Register (ENETx\_RMON\_R\_FRAG)

Address: 402D\_4000h base + 29Ch offset = 402D\_429Ch

#### ENETx\_RMON\_R\_FRAG field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Number of receive packets with less than 64 bytes and bad CRC

### 40.6.72 Rx Packets Greater Than MAX\_FL Bytes and Bad CRC Statistic Register (ENETx\_RMON\_R\_JAB)

Address: 402D\_4000h base + 2A0h offset = 402D\_42A0h

**ENETx\_RMON\_R\_JAB field descriptions**

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Number of receive packets greater than MAX_FL and bad CRC

**40.6.73 Reserved Statistic Register (ENETx\_RMON\_R\_RESVD\_0)**

Address: 402D\_4000h base + 2A4h offset = 402D\_42A4h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**ENETx\_IEEE\_R\_CRC field descriptions**

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Number of frames received with CRC error

### 40.6.85 Frames Received with Alignment Error Statistic Register (ENETx\_IEEE\_R\_ALIGN)

Address: 402D\_4000h base + 2D4h offset = 402D\_42D4h

#### ENETx\_IEEE\_R\_ALIGN field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Number of frames received with alignment error

### 40.6.86 Receive FIFO Overflow Count Statistic Register (ENETx\_IEEE\_R\_MACERR)

Address: 402D\_4000h base + 2D8h offset = 402D\_42D8h

#### ENETx\_IEEE\_R\_MACERR field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Receive FIFO overflow count

### 40.6.87 Flow Control Pause Frames Received Statistic Register (ENETx\_IEEE\_R\_FDXFC)

Address: 402D\_4000h base + 2DCh offset = 402D\_42DCh

**ENETx\_IEEE\_R\_FDXFC field descriptions**

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Number of flow-control pause frames received

**40.6.88 Octet Count for Frames Received without Error Statistic Register (ENETx\_IEEE\_R\_OCTETS\_OK)**

Address: 402D\_4000h base + 2E0h offset = 402D\_42E0h

**ENETx\_IEEE\_R\_OCTETS\_OK field descriptions**

Field	Description
COUNT	Number of octets for frames received without error  <b>NOTE:</b> Counts total octets (includes header and FCS fields). Does not increment for the broadcast frames when broadcast reject is enabled and promiscuous mode is disabled within the receive control register (RCR).

**40.6.89 Adjustable Timer Control Register (ENETx\_ATCR)**

ATCR command fields can trigger the corresponding events directly. It is not necessary to preserve any of the configuration fields when a command field is set in the register, that is, no read-modify-write is required.

**NOTE**

The CAPTURE and RESTART fields and bits 12 and 10 must be 0 in order to write to the other fields in this register.

Address: 402D\_4000h base + 400h offset = 402D\_4400h

**Memory map/register definition**

**ENETx\_ATCR field descriptions**

Field	Description
31–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 SLAVE	Enable Timer Slave Mode  0 The timer is active and all configuration fields in this register are relevant. 1 The internal timer is disabled and the externally provided timer value is used. All other fields, except CAPTURE, in this register have no effect. CAPTURE can still be used to capture the current timer value.
12 Reserved	This field is reserved. Always write 0 to this field.
11 CAPTURE	Capture Timer Value  When this field is set, all other fields are ignored during a write. This field automatically clears to 0 after the command completes.  0 No effect. 1 The current time is captured and can be read from the ATVR register.
10 Reserved	This field is reserved. Always write 0 to this field.
9 RESTART	Reset Timer  Resets the timer to zero. This has no effect on the counter enable. If the counter is enabled when this field is set, the timer is reset to zero and starts counting from there. When set, all other fields are ignored during a write. This field automatically clears to 0 after the command completes. RESTART should be used when the timer is enabled.
8 Reserved	This field is reserved.
7 PINPER	Enables event signal output assertion on period event. <b>NOTE:</b> Not all devices contain the event signal output. See the chip configuration details.  0 Disable. 1 Enable.
6 Reserved	This field is reserved.
5 Reserved	This field is reserved. <b>NOTE:</b> This field must be written always with one.
4 PEREN	Enable Periodical Event

*Table continues on the next page...*

## ENETx\_ATCR field descriptions (continued)

Field	Description
	0 Disable. 1 A period event interrupt can be generated (EIR[TS_TIMER]) and the event signal output is asserted when the timer wraps around according to the periodic setting ATPER. The timer period value must be set before setting this bit.  <b>NOTE:</b> Not all devices contain the event signal output. See the chip configuration details.
3 OFFRST	Reset Timer On Offset Event  0 The timer is not affected and no action occurs, besides clearing OFFEN, when the offset is reached. 1 If OFFEN is set, the timer resets to zero when the offset setting is reached. The offset event does not cause a timer interrupt.
2 OFFEN	Enable One-Shot Offset Event  0 Disable. 1 The timer can be reset to zero when the given offset time is reached (offset event). The field is cleared when the offset event is reached, so no further event occurs until the field is set again. The timer offset value must be set before setting this field.
1 Reserved	This field is reserved.
0 EN	Enable Timer  0 The timer stops at the current value. 1 The timer starts incrementing.

## 40.6.90 Timer Value Register (ENETx\_ATVR)

Address: 402D\_4000h base + 404h offset = 402D\_4404h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## ENETx\_ATVR field descriptions

Field	Description
ATIME	A write sets the timer. A read returns the last captured value. To read the current value, issue a capture command (i.e., set ATCR[CAPTURE]) prior to reading this register.

## 40.6.91 Timer Offset Register (ENETx\_ATOFF)

Address: 402D\_4000h base + 408h offset = 402D\_4408h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
R																		OFFSET																
W																																		
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0		

### ENETx\_ATOFF field descriptions

Field	Description
OFFSET	Offset value for one-shot event generation. When the timer reaches the value, an event can be generated to reset the counter. If the increment value in ATINC is given in true nanoseconds, this value is also given in true nanoseconds.

### 40.6.92 Timer Period Register (ENETx\_ATPER)

Address: 402D\_4000h base + 40Ch offset = 402D\_440Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																																
W																																
Reset	0	0	1	1	1	0	1	1	1	0	0	1	1	0	1	0	1	1	0	0	1	0	1	0	0	0	0	0	0	0	0	0

### ENETx\_ATPER field descriptions

Field	Description
PERIOD	Value for generating periodic events. Each instance the timer reaches this value, the period event occurs and the timer restarts. If the increment value in ATINC is given in true nanoseconds, this value is also given in true nanoseconds. The value should be initialized to 1,000,000,000 (1×10 <sup>9</sup> ) to represent a timer wrap around of one second. The increment value set in ATINC should be set to the true nanoseconds of the period of clock ts_clk, hence implementing a true 1 second counter.  <b>NOTE:</b> The value of PERIOD has the following constraint: $2^{32} - \text{ENET\_ATINC}[\text{INC\_COR}] - 3 \times \text{ENET\_ATINC}[\text{INC}] \geq \text{PERIOD} > 0.$

### 40.6.93 Timer Correction Register (ENETx\_ATCOR)

Address: 402D\_4000h base + 410h offset = 402D\_4410h

### ENETx\_TCSRn field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15–11 TPWC	Timer PulseWidth Control  Specifies the pulse width associated with TMODE values of 1110 or 11X1. Updating this field takes a few cycles to register because it is synchronized to the 1588 clock. When changing this field: <ol style="list-style-type: none"> <li>1. Always disable the channel and read the TMODE field to verify that the channel is disabled.</li> <li>2. Set TPWC to the desired value.</li> <li>3. Reenable the channel.</li> </ol> 00000 Pulse width is one 1588-clock cycle. 00001 Pulse width is two 1588-clock cycles. 00010 Pulse width is three 1588-clock cycles. 00011 Pulse width is four 1588-clock cycles. ... .. 11111 Pulse width is 32 1588-clock cycles.
10–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 TF	Timer Flag  Sets when input capture or output compare occurs. This flag is double buffered between the module clock and 1588 clock domains. When this field is 1, it can be cleared to 0 by writing 1 to it.  0 Input Capture or Output Compare has not occurred. 1 Input Capture or Output Compare has occurred.
6 TIE	Timer Interrupt Enable  0 Interrupt is disabled 1 Interrupt is enabled
5–2 TMODE	Timer Mode

Table continues on the next page...

**ENETx\_TCSRn field descriptions (continued)**

Field	Description
	Updating the Timer Mode field takes a few cycles to register because it is synchronized to the 1588 clock. The version of Timer Mode returned on a read is from the 1588 clock domain. When changing Timer Mode, always disable the channel and read this register to verify the channel is disabled first.
	0000 Timer Channel is disabled.
	0001 Timer Channel is configured for Input Capture on rising edge.
	0010 Timer Channel is configured for Input Capture on falling edge.
	0011 Timer Channel is configured for Input Capture on both edges.
	0100 Timer Channel is configured for Output Compare - software only.
	0101 Timer Channel is configured for Output Compare - toggle output on compare.
	0110 Timer Channel is configured for Output Compare - clear output on compare.
	0111 Timer Channel is configured for Output Compare - set output on compare.
	1000 Reserved
	1010 Timer Channel is configured for Output Compare - clear output on compare, set output on overflow.
	10X1 Timer Channel is configured for Output Compare - set output on compare, clear output on overflow.
	110X Reserved
	1110 Timer Channel is configured for Output Compare - pulse output low on compare for 1 to 32 1588-clock cycles as specified by TPWC.
	1111 Timer Channel is configured for Output Compare - pulse output high on compare for 1 to 32 1588-clock cycles as specified by TPWC.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 TDRE	Timer DMA Request Enable 0 DMA request is disabled 1 DMA request is enabled

**40.6.98 Timer Compare Capture Register (ENETx\_TCCRn)**

Address: 402D\_4000h base + 60Ch offset + (8d × i), where i=0d to 3d

**ENETx\_TCCRn field descriptions**

Field	Description
TCC	Timer Capture Compare  This register is double buffered between the module clock and 1588 clock domains.  When configured for compare, the 1588 clock domain updates with the value in the module clock domain whenever the Timer Channel is first enabled and on each subsequent compare. Write to this register with the first compare value before enabling the Timer Channel. When the Timer Channel is enabled, write the second compare value either immediately, or at least before the first compare occurs. After each compare, write the next compare value before the previous compare occurs and before clearing the Timer Flag.

**ENETx\_TCCR<sub>n</sub> field descriptions (continued)**

Field	Description
	<p>The compare occurs one 1588 clock cycle after the IEEE 1588 Counter increments past the compare value in the 1588 clock domain. If the compare value is less than the value of the 1588 Counter when the Timer Channel is first enabled, then the compare does not occur until following the next overflow of the 1588 Counter. If the compare value is greater than the IEEE 1588 Counter when the 1588 Counter overflows, or the compare value is less than the value of the IEEE 1588 Counter after the overflow, then the compare occurs one 1588 clock cycle following the overflow.</p> <p>When configured for capture, the value of the IEEE 1588 Counter is captured into the 1588 clock domain and then updated into the module clock domain, provided the Timer Flag is clear. Always read the capture value before clearing the Timer Flag.</p>

## 40.7 Functional description

This section provides a complete functional description of the MAC-NET core.

### 40.7.1 Ethernet MAC frame formats

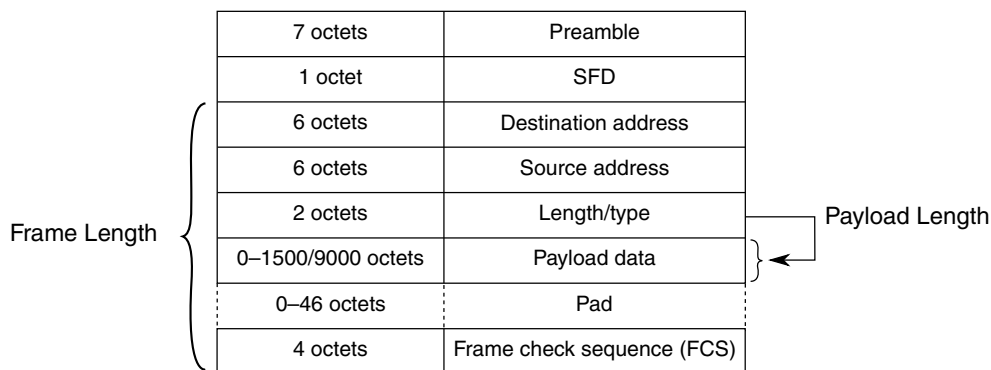

The IEEE 802.3 standard defines the Ethernet frame format as follows:

- Minimum length of 64 bytes
- Maximum length of 1518 bytes excluding the preamble and the start frame delimiter (SFD) bytes

An Ethernet frame consists of the following fields:

- Seven bytes preamble
- Start frame delimiter (SFD)
- Two address fields
- Length or type field
- Data field
- Frame check sequence (CRC value)

## Functional description

**Figure 40-2. MAC frame format overview**

Optionally, MAC frames can be VLAN-tagged with an additional four-byte field inserted between the MAC source address and the type/length field. VLAN tagging is defined by the IEEE P802.1q specification. VLAN-tagged frames have a maximum length of 1522 bytes, excluding the preamble and the SFD bytes.

**Figure 40-3. VLAN-tagged MAC frame format overview**

**Table 40-6. MAC frame definition**

Term	Description
Frame length	Defines the length, in octets, of the complete frame without preamble and SFD. A frame has a valid length if it contains at least 64 octets and does not exceed the programmed maximum length.
Payload length	The length/type field indicates the length of the frame's payload section. The most significant byte is sent/received first. <ul style="list-style-type: none"> <li>If the length/type field is set to a value less than 46, the payload is padded so that the minimum frame length requirement (64 bytes) is met. For VLAN-tagged frames, a value less than 42 indicates a padded frame.</li> <li>If the length/type field is set to a value larger than the programmed frame maximum length (e.g. 1518) it is interpreted as a type field.</li> </ul>
Destination and source address	48-bit MAC addresses. The least significant byte is sent/received first and the first two least significant bits of the MAC address distinguish MAC frames, as detailed in <a href="#">MAC address check</a> .

## Note

Although the IEEE specification defines a maximum frame length, the MAC core provides the flexibility to program any value for the frame maximum length.

### 40.7.1.1 Pause Frames

The receiving device generates a pause frame to indicate a congestion to the emitting device, which should stop sending data.

Pause frames are indicated by the length/type set to 0x8808. The two first bytes of a pause frame following the type, defines a 16-bit opcode field set to 0x0001 always. A 16-bit pause quanta is defined in the frame payload bytes 2 (P1) and 3 (P2) as defined in the following table. The P1 pause quanta byte is the most significant.

**Table 40-7. Pause Frame Format (Values in Hex)**

1	2	3	4	5	6	7	8	9	10	11	12	13	14
55	55	55	55	55	55	55	D5	01	80	C2	00	00	01
Preamble							SFD	Multicast Destination Address					
15	16	17	18	19	20	21	22	23	24	25	26	27–68	
00	00	00	00	00	00	88	08	00	01	hi	lo	00	
Source Address						Type		Opcode		P1	P2	pad (42)	
69	70	71	72										
26	6B	AE	0A										
CRC-32													

There is no payload length field found within a pause frame and a pause frame is always padded with 42 bytes (0x00).

If a pause frame with a pause value greater than zero (XOFF condition) is received, the MAC stops transmitting data as soon the current frame transfer is completed. The MAC stops transmitting data for the value defined in pause quanta. One pause quanta fraction refers to 512 bit times.

If a pause frame with a pause value of zero (XON condition) is received, the transmitter is allowed to send data immediately (see [Full-duplex flow control operation](#) for details).

### 40.7.1.2 Magic packets

A magic packet is a unicast, multicast, or broadcast packet, which carries a defined sequence in the payload section.

Magic packets are received and inspected only under specific conditions as described in [Magic packet detection](#).

The defined sequence to decode a magic packet is formed with a synchronization stream which consists of six consecutive 0xFF bytes, and is followed by sequence of sixteen consecutive unicast MAC addresses of the node to be awakened.

This sequence can be located anywhere in the magic packet payload. The magic packet is formed with a standard Ethernet header, optional padding, and CRC.

## 40.7.2 IP and higher layers frame format

The following sections use the term datagram to describe the protocol specific data unit that is found within the payload section of its container entity.

For example, an IP datagram specifies the payload section of an Ethernet frame. A TCP datagram specifies the payload section within an IP datagram.

### 40.7.2.1 Ethernet types

IP datagrams are carried in the payload section of an Ethernet frame. The Ethernet frame type/length field discriminates several datagram types.

The following table lists the types of interest:

**Table 40-8. Ethernet type value examples**

Type	Description
0x8100	VLAN-tagged frame. The actual type is found 4 octets later in the frame.
0x0800	IPv4
0x0806	ARP
0x86DD	IPv6

### 40.7.2.2 IPv4 datagram format

The following figure shows the IP Version 4 (IPv4) header, which is located at the beginning of an IP datagram. It is organized in 32-bit words. The first byte sent/received is the leftmost byte of the first word (in other words, version/IHL field).

The IP header can contain further options, which are always padded if necessary to guarantee the payload following the header is aligned to a 32-bit boundary.

The IP header is immediately followed by the payload, which can contain further protocol headers (for example, TCP or UDP, as indicated by the protocol field value). The complete IP datagram is transported in the payload section of an Ethernet frame.

**Table 40-9. IPv4 header format**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Version				IHL				TOS				Length																			
Fragment ID								Flags				Fragment offset																			
TTL				Protocol				Header checksum																							
Source address																															
Destination address																															
Options																															

**Table 40-10. IPv4 header fields**

Field name	Description
Version	4-bit IP version information. 0x4 for IPv4 frames.
IHL	4-bit Internet header length information. Determines number of 32-bit words found within the IP header. If no options are present, the default value is 0x5.
TOS	Type of service/DiffServ field.
Length	Total length of the datagram in bytes, including all octets of header and payload.
Fragment ID, flags, fragment offset	Fields used for IP fragmentation.
TTL	Time-to-live. In effect, is decremented at each router arrival. If zero, datagram must be discarded.
Protocol	Identifier of protocol that follows in the datagram.
Header checksum	Checksum of IP header. For computational purposes, this field's value is zero.
Source address	Source IP address.
Destination address	Destination IP address.

### 40.7.2.3 IPv6 datagram format

The following figure shows the IP version 6 (IPv6) header, which is located at the beginning of an IP datagram. It is organized in 32-bit words and has a fixed length of ten words (40 bytes). The next header field identifies the type of the header that follows the IPv6 header. It is defined similar to the protocol identifier within IPv4, with new definitions for identifying extension headers. These headers can be inserted between the IPv6 header and the protocol header, which will shift the protocol header accordingly. The accelerator currently only supports IPv6 without extension headers (in other words, the next header specifies TCP, UDP, or ICMP).

## Functional description

The first byte sent/received is the leftmost byte of the first word (in other words, version/traffic class fields).

**Figure 40-4. IPv6 header format**

**Table 40-11. IPv6 header fields**

Field name	Description
Version	4-bit IP version information. 0x6 for all IPv6 frames.
Traffic class	8-bit field defining the traffic class.
Flow label	20-bit flow label identifying frames of the same flow.
Payload length	16-bit length of the datagram payload in bytes. It includes all octets following the IPv6 header.
Next header	Identifies the header that follows the IPv6 header. This can be the protocol header or any IPv6 defined extension header.
Hop limit	Hop counter, decremented by one by each station that forwards the frame. If hop limit is 0 the frame must be discarded.
Source address	128-bit IPv6 source address.
Destination address	128-bit IPv6 destination address.

### 40.7.2.4 Internet Control Message Protocol (ICMP) datagram format

An internet control message protocol (ICMP) is found following the IP header, if the protocol identifier is 1. The ICMP datagram has a four-octet header followed by additional message data.

**Table 40-12. ICMP header format**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Type				Code								Checksum																			
ICMP message data																															

**Table 40-13. IP header fields**

Field name	Description
Type	8-bit type information
Code	8-bit code that is related to the message type
Checksum	16-bit one's complement checksum over the complete ICMP datagram

### 40.7.2.5 User Datagram Protocol (UDP) datagram format

A user datagram protocol header is found after the IP header, when the protocol identifier is 17.

The payload of the datagram is after the UDP header. The header byte order follows the conventions given for the IP header above.

**Table 40-14. UDP header format**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Source port																Destination port															
Length																Checksum															

**Table 40-15. UDP header fields**

Field name	Description
Source port	Source application port
Destination port	Destination application port
Length	Length of user data which immediately follows the header, including the UDP header (that is, minimum value is 8)
Checksum	Checksum over the complete datagram and some IP header information

### 40.7.2.6 TCP datagram format

A TCP header is found following the IP header, when the protocol identifier has a value of 6.

The TCP payload immediately follows the TCP header.

**Table 40-16. TCP header format**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Source port																Destination port															

*Table continues on the next page...*

**Table 40-16. TCP header format (continued)**

Sequence number			
Acknowledgement number			
Offset	Reserved	Flags	Window
Checksum		Urgent pointer	
Options			

**Table 40-17. TCP header fields**

Field name	Description
Source port	Source application port
Destination port	Destination application port
Sequence number	Transmit sequence number
Ack. number	Receive sequence number
Offset	Data offset, which is number of 32-bit words within TCP header — if no options selected, defaults to value of 5
Flags	URG, ACK, PSH, RST, SYN, FIN flags
Window	TCP receive window size information
Checksum	Checksum over the complete datagram (TCP header and data) and IP header information
Options	Additional 32-bit words for protocol options

### 40.7.3 IEEE 1588 message formats

The following sections describe the IEEE 1588 message formats.

#### 40.7.3.1 Transport encapsulation

The precision time protocol (PTP) datagrams are encapsulated in Ethernet frames using the UDP/IP transport mechanism, or optionally, with the newer 1588v2 directly in Ethernet frames (layer 2).

Typically, multicast addresses are used to allow efficient distribution of the synchronization messages.

##### 40.7.3.1.1 UDP/IP

The 1588 messages (v1 and v2) can be transported using UDP/IP multicast messages.

Table 40-18 shows IP multicast groups defined for PTP. The table also shows their respective MAC layer multicast address mapping according to RFC 1112 (last three octets of IP follow the fixed value of 01-00-5E).

**Table 40-18. UDP/IP multicast domains**

Name	IP Address	MAC Address mapping
DefaultPTPdomain	224.0.1.129	01-00-5E-00-01-81
AlternatePTPdomain1	224.0.1.130	01-00-5E-00-01-82
AlternatePTPdomain2	224.0.1.131	01-00-5E-00-01-83
AlternatePTPdomain3	224.0.1.132	01-00-5E-00-01-84

**Table 40-19. UDP port numbers**

Message type	UDP port	Note
Event	319	Used for SYNC and DELAY_REQUEST messages
General	320	All other messages (for example, follow-up, delay-response)

#### 40.7.3.1.2 Native Ethernet (PTPv2)

In addition to using UDP/IP frames, IEEE 1588v2 defines a native Ethernet frame format that uses ethertype = 0x88F7. The payload of the Ethernet frame immediately contains the PTP datagram, starting with the PTPv2 header.

Besides others, version 2 adds a peer delay mechanism to allow delay measurements between individual point-to-point links along a path over multiple nodes. The following multicast domains are also defined in PTPv2.

**Table 40-20. PTPv2 multicast domains**

Name	MAC address
Normal messages	01-1B-19-00-00-00
Peer delay messages	01-80-C2-00-00-0E

#### 40.7.3.2 PTP header

All PTP frames contain a common header that determines the protocol version and the type of message, which defines the remaining content of the message.

All multi-octet fields are transmitted in big-endian order (the most significant byte is transmitted/received first).

## Functional description

The last four bits of versionPTP are at the same position (second byte) for PTPv1 and PTPv2 headers. This allows accurate identification by inspecting the first two bytes of the message.

### 40.7.3.2.1 PTPv1 header

Table 40-21. Common PTPv1 message header

Offset	Octets	Bits							
		7	6	5	4	3	2	1	0
0	2	versionPTP = 0x0001							
2	2	versionNetwork							
4	16	subdomain							
20	1	messageType							
21	1	sourceCommunicationTechnology							
22	6	sourceUuid							
28	2	sourcePortId							
30	2	sequenceId							
32	1	control							
33	1	0x00							
34	2	flags							
36	4	reserved							

The type of message is encoded in the messageType and control fields as shown in [Table 40-22](#) :

Table 40-22. PTPv1 message type identification

messageType	control	Message Name	Message
0x01	0x0	SYNC	Event message
0x01	0x1	DELAY_REQ	Event message
0x02	0x2	FOLLOW_UP	General message
0x02	0x3	DELAY_RESP	General message
0x02	0x4	MANAGEMENT	General message
other	other	—	Reserved

The field sequenceId is used to non-ambiguously identify a message.

## 40.7.3.2.2 PTPv2 header

Table 40-23. Common PTPv2 message header

Offset	Octets	Bits							
		7	6	5	4	3	2	1	0
0	1	transportSpecific				messageId			
1	1	reserved				versionPTP = 0x2			
2	2	messageLength							
4	1	domainNumber							
5	1	reserved							
6	2	flags							
8	8	correctionField							
16	4	reserved							
20	10	sourcePortIdentity							
30	2	sequenceId							
32	1	control							
33	1	logMeanMessageInterval							

The type of message is encoded in the field messageId as follows:

Table 40-24. PTPv2 message type identification

messageId	Message name	Message
0x0	SYNC	Event message
0x1	DELAY_REQ	Event message
0x2	PATH_DELAY_REQ	Event message
0x3	PATH_DELAY_RESP	Event message
0x4–0x7	—	Reserved
0x8	FOLLOW_UP	General message
0x9	DELAY_RESP	General message
0xa	PATH_DELAY_FOLLOW_UP	General message
0xb	ANNOUNCE	General message
0xc	SIGNALING	General message
0xd	MANAGEMENT	General message

The PTPv2 flags field contains further details on the type of message, especially if one-step or two-step implementations are used. The one- or two-step implementation is controlled by the TWO\_STEP bit in the first octet of the flags field as shown below. Reserved bits are cleared.

**Table 40-25. PTPv2 message flags field definitions**

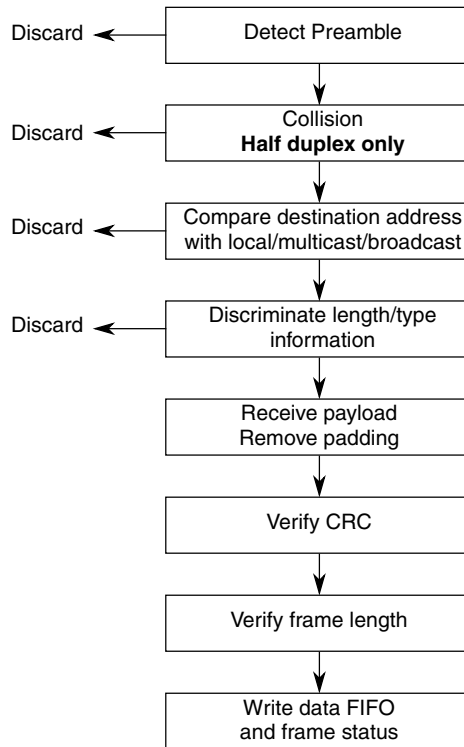

Bit	Name	Description
0	ALTERNATE_MASTER	See IEEE 1588 Clause 17.4
1	TWO_STEP	1 Two-step clock 0 One-step clock
2	UNICAST	1 Transport layer address uses a unicast destination address 0 Multicast is used
3	—	Reserved
4	—	Reserved
5	Profile specific	
6	Profile specific	
7	—	Reserved

#### 40.7.4 MAC receive

The MAC receive engine performs the following tasks:

- Check frame framing
- Remove frame preamble and frame SFD field
- Discard frame based on frame destination address field
- Terminate pause frames
- Check frame length
- Remove payload padding if it exists
- Calculate and verify CRC-32
- Write received frames in the core receive FIFO

If the MAC is programmed to operate in half-duplex mode, it will also check if the frame is received with a collision.

**Figure 40-5. MAC receive flow**

#### 40.7.4.1 Collision detection in half-duplex mode

If the packet is received with a collision detected during reception of the first 64 bytes, the packet is discarded (if frame size was less than ~14 octets) or transmitted to the user application with an error and RxBD[CE] set.

#### 40.7.4.2 Preamble processing

The IEEE 802.3 standard allows a maximum size of 56 bits (seven bytes) for the preamble, while the MAC core allows any preamble length, including zero length preamble.

The MAC core checks for the start frame delimiter (SFD) byte. If the next byte of the preamble, which is different from 0x55, is not 0xD5, the frame is discarded.

Although the IEEE specification dictates that the inner-packet gap should be at least 96 bits, the MAC core is designed to accept frames separated by only 64 10/100-Mbit/s operation (MII) bits.

The MAC core removes the preamble and SFD bytes.

### 40.7.4.3 MAC address check

The destination address bit 0 differentiates between multicast and unicast addresses.

- If bit 0 is 0, the MAC address is an individual (unicast) address.
- If bit 0 is 1, the MAC address defines a group (multicast) address.
- If all 48 bits of the MAC address are set, it indicates a broadcast address.

#### 40.7.4.3.1 Unicast address check

If a unicast address is received, the destination MAC address is compared to the node MAC address programmed by the host in the PADDR1/2 registers.

If the destination address matches any of the programmed MAC addresses, the frame is accepted.

If Promiscuous mode is enabled ( $RCR[PROM] = 1$ ) no address checking is performed and all unicast frames are accepted.

#### 40.7.4.3.2 Multicast and unicast address resolution

The hash table algorithm used in the group and individual hash filtering operates as follows.

- The 48-bit destination address is mapped into one of 64 bits, represented by 64 bits in  $ENETn\_GAUR/GALR$  (group address hash match) or  $ENETn\_IAUR/IALR$  (individual address hash match).
- This mapping is performed by passing the 48-bit address through the on-chip 32-bit CRC generator and selecting the six most significant bits of the CRC-encoded result to generate a number between 0 and 63.
- The msb of the CRC result selects  $ENETn\_GAUR$  (msb = 1) or  $ENETn\_GALR$  (msb = 0).
- The five lsbs of the hash result select the bit within the selected register.
- If the CRC generator selects a bit set in the hash table, the frame is accepted; else, it is rejected.

For example, if eight group addresses are stored in the hash table and random group addresses are received, the hash table prevents roughly 56/64 (or 87.5%) of the group address frames from reaching memory. Those that do reach memory must be further filtered by the processor to determine if they truly contain one of the eight desired addresses.

The effectiveness of the hash table declines as the number of addresses increases.

The user must initialize the hash table registers. Use this CRC32 polynomial to compute the hash:

- $FCS(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x^1 + 1$

If Promiscuous mode is enabled ( $ENETn\_RCR[PROM] = 1$ ) all unicast and multicast frames are accepted regardless of  $ENETn\_GAUR/GALR$  and  $ENETn\_IAUR/IALR$  settings.

#### 40.7.4.3.3 Broadcast address reject

All broadcast frames are accepted if  $BC\_REJ$  is cleared or  $ENETn\_RCR[PROM]$  is set. If  $PROM$  is cleared when  $ENETn\_RCR[BC\_REJ]$  is set, all broadcast frames are rejected.

**Table 40-26. Broadcast address reject programming**

PROM	BC_REJ	Broadcast frames
0	0	Accepted
0	1	Rejected
1	0	Accepted
1	1	Accepted

#### 40.7.4.3.4 Miss-bit implementation

For higher layer filtering purposes,  $RxBD[M]$  indicates an address miss when the MAC operates in promiscuous mode and accepts a frame that would otherwise be rejected.

If a group/individual hash or exact match does not occur and Promiscuous mode is enabled ( $RCR[PROM] = 1$ ), the frame is accepted and the M bit is set in the buffer descriptor; otherwise, the frame is rejected.

This means the status bit is set in any of the following conditions during Promiscuous mode:

- A broadcast frame is received when  $BC\_REJ$  is set
- A unicast is received that does not match either:

- Node address (PALR[PADDR1] and PAUR[PADDR2])
- Hash table for unicast (IAUR[IADDR1] and IALR[IADDR2])
- A multicast is received that does not match the GAUR[GADDR1] and GALR[GADDR2] hash table entries

#### 40.7.4.4 Frame length/type verification: payload length check

If the length/type is less than 0x600 and NLC is set, the MAC checks the payload length and reports any error in the frame status word and interrupt bit PLR.

If the length/type is greater than or equal to 0x600, the MAC interprets the field as a type and no payload length check is performed.

The length check is performed on VLAN and stacked VLAN frames. If a padded frame is received, no length check can be performed due to the extended frame payload because padded frames can never have a payload length error.

#### 40.7.4.5 Frame length/type verification: frame length check

When the receive frame length exceeds MAX\_FL bytes, the BABR interrupt is generated and the RxBD[LG] bit is set.

The frame is not truncated unless the frame length exceeds the value programmed in ENET $n$ \_FTRL[TRUNC\_FL]. If the frame is truncated, RxBD[TR] is set. In addition, a truncated frame always has the CRC error indication set (RxBD[CR]).

#### 40.7.4.6 VLAN frames processing

VLAN frames have a length/type field set to 0x8100 immediately followed by a 16-Bit VLAN control information field.

VLAN-tagged frames are received as normal frames because the VLAN tag is not interpreted by the MAC function, and are pushed complete with the VLAN tag to the user application. If the length/type field of the VLAN-tagged frame, which is found four octets later in the frame, is less than 42, the padding is removed. In addition, the frame status word (RxBD[NO]) indicates that the current frame is VLAN tagged.

#### 40.7.4.7 Pause frame termination

The receive engine terminates pause frames and does not transfer them to the receive FIFO. The quanta is extracted and sent to the MAC transmit path via a small internal clock rate decoupling asynchronous FIFO.

The quanta is written only if a correct CRC and frame length are detected by the control state machine. If not, the quanta is discarded and the MAC transmit path is not paused.

Good pause frames are ignored if ENET $n$ \_RCR[FCE] is cleared and are forwarded to the client interface when ENET $n$ \_RCR[PAUFWD] is set.

#### 40.7.4.8 CRC check

The CRC-32 field is checked and forwarded to the core FIFO interface if ENET $n$ \_RCR[CRCFWD] is cleared and ENET $n$ \_RCR[PADEN] is cleared. When CRCFWD is set (regardless of PADEN), the CRC-32 field is checked and terminated (not transmitted to the FIFO).

The CRC polynomial, as specified in the 802.3 standard, is:

- $FCS(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x^1 + 1$

The 32 bits of the CRC value are placed in the frame check sequence (FCS) field with the  $x^{31}$  term as right-most bit of the first octet. The CRC bits are thus received in the following order:  $x^{31}, x^{30}, \dots, x^1, x^0$ .

If a CRC error is detected, the frame is marked invalid and RxBD[CR] is set.

#### 40.7.4.9 Frame padding removal

When a frame is received with a payload length field set to less than 46 (42 for VLAN-tagged frames and 38 for frames with stacked VLANs), the zero padding can be removed before the frame is written into the data FIFO depending on the setting of ENET $n$ \_RCR[PADEN].

#### Note

If a frame is received with excess padding (in other words, the length field is set as mentioned above, but the frame has more than 64 octets) and padding removal is enabled, then the

padding is removed as normal and no error is reported if the frame is otherwise correct (for example: good CRC, less than maximum length, and no other error).

## 40.7.5 MAC transmit

Frame transmission starts when the transmit FIFO holds enough data.

After a transfer starts, the MAC transmit function performs the following tasks:

- Generates preamble and SFD field before frame transmission
- Generates XOFF pause frames if the receive FIFO reports a congestion or if ENET $n$ \_TCR[TFC\_PAUSE] is set with ENET $n$ \_OPD[PAUSE\_DUR] set to a non-zero value
- Generates XON pause frames if the receive FIFO congestion condition is cleared or if TFC\_PAUSE is set with PAUSE\_DUR cleared
- Suspends Ethernet frame transfer (XOFF) if a non-zero pause quanta is received from the MAC receive path
- Adds padding to the frame if required
- Calculates and appends CRC-32 to the transmitted frame
- Sends the frame with correct inter-packet gap (IPG) (deferring)

When the MAC is configured to operate in half-duplex mode, the following additional tasks are performed:

- Collision detection
- Frame retransmit after back-off timer expires

**Figure 40-6. Frame transmit overview**

### 40.7.5.1 Frame payload padding

The IEEE specification defines a minimum frame length of 64 bytes.

If the frame sent to the MAC from the user application has a size smaller than 60 bytes, the MAC automatically adds padding bytes (0x00) to comply with the Ethernet minimum frame length specification. Transmit padding is always performed and cannot be disabled.

If the MAC is not allowed to append a CRC (TxBD[TC] = 1), the user application is responsible for providing frames with a minimum length of 64 octets.

### 40.7.5.2 MAC address insertion

On each frame received from the core transmit FIFO interface, the source MAC address is either:

- Replaced by the address programmed in the PADDR1/2 fields (ENET $n$ \_TCR[ADDINS] = 1)
- Transparently forwarded to the Ethernet line (ENET $n$ \_TCR[ADDINS] = 0)

### 40.7.5.3 CRC-32 generation

The CRC-32 field is optionally generated and appended at the end of a frame.

The CRC polynomial, as specified in the 802.3 standard, is:

- $FCS(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x^1 + 1$

The 32 bits of the CRC value are placed in the FCS field so that the  $x^{31}$  term is the right-most bit of the first octet. The CRC bits are thus transmitted in the following order:  $x^{31}$ ,  $x^{30}$ , ...,  $x^1$ ,  $x^0$ .

#### **40.7.5.4 Inter-packet gap (IPG)**

In full-duplex mode, after frame transmission and before transmission of a new frame, an IPG (programmed in `ENETn_TIPG`) is maintained. The minimum IPG can be programmed between 8 and 26 byte-times (64 and 208 bit-times).

In half-duplex mode, the core constantly monitors the line. Actual transmission of the data onto the network occurs only if it has been idle for a 96-bit time period, and any back-off time requirements have been satisfied. In accordance with the standard, the core begins to measure the IPG from CRS de-assertion.

#### **40.7.5.5 Collision detection and handling — half-duplex operation only**

A collision occurs on a half-duplex network when concurrent transmissions from two or more nodes take place. During transmission, the core monitors the line condition and detects a collision when the PHY device asserts COL.

When the core detects a collision while transmitting, it stops transmission of the data and transmits a 32-bit jam pattern. If the collision is detected during the preamble or the SFD transmission, the jam pattern is transmitted after completing the SFD, which results in a minimum 96-bit fragment. The jam pattern is a fixed pattern that is not compared to the actual frame CRC, and has a very low probability (0.532) of having a jam pattern identical to the CRC.

If a collision occurs before transmission of 64 bytes (including preamble and SFD), the MAC core waits for the backoff period and retransmits the packet data (stored in a 64-byte re-transmit buffer) that has already been sent on the line. The backoff period is generated from a pseudo-random process (truncated binary exponential backoff).

If a collision occurs after transmission of 64 bytes (including preamble and SFD), the MAC discards the remainder of the frame, optionally sets the LC interrupt bit, and sets `TxBD[LCE]`.

**Figure 40-7. Packet re-transmit overview**

The backoff time is represented by an integer multiple of slot times. One slot is equal to a 512-bit time period. The number of the delay slot times, before the  $n^{\text{th}}$  re-transmission attempt, is chosen as a uniformly-distributed random integer in the range:

- $0 < r < 2^k$
- $k = \min(n, N)$ ; where  $n$  is the number of retransmissions and  $N = 10$

For example, after the first collision, the backoff period is 0 or 1 slot time. If a collision occurs on the first retransmission, the backoff period is 0, 1, 2, or 3, and so on.

The maximum backoff time (in 512-bit time slots) is limited by  $N = 10$  as specified in the IEEE 802.3 standard.

If a collision occurs after 16 consecutive retransmissions, the core reports an excessive collision condition (ENET $n$ \_EIR[RL] interrupt field and TxBD[EE]) and discards the current packet from the FIFO.

In networks violating the standard requirements, a collision may occur after transmission of the first 64 bytes. In this case, the core stops the current packet transmission and discards the rest of the packet from the transmit FIFO. The core resumes transmission with the next packet available in the core transmit FIFO.

### warning

Ethernet PHYs that support the SQE Test, or "heartbeat," feature must disable this feature. When this feature is enabled,

the PHY asserts the collision signal after a frame is transmitted to indicate to the ENET that the PHY's collision logic is working. This may cause data corruption in the next frame from the ENET. This corrupted frame contains up to 21 zero bytes which start somewhere within the MAC destination address field. The ENET, however, will still generate a good FCS (CRC-32) but with corrupted data.

## 40.7.6 Full-duplex flow control operation

Three conditions are handled by the core's flow control engine:

- Remote device congestion — The remote device connected to the same Ethernet segment as the core reports congestion and requests that the core stop sending data.
- Core FIFO congestion — When the core's receive FIFO reaches a user-programmable threshold (RX section empty), the core sends a pause frame back to the remote device requesting the data transfer to stop.
- Local device congestion — Any device connected to the core can request (typically, via the host processor) the remote device to stop transmitting data.

### 40.7.6.1 Remote device congestion

When the MAC transmit control gets a valid pause quanta from the receive path and if `ENETn_RCR[FCE]` is set, the MAC transmit logic:

- Completes the transfer of the current frame.
- Stops sending data for the amount of time specified by the pause quanta in 512 bit time increments.
- Sets `ENETn_TCR[RFC_PAUSE]`.

Frame transfer resumes when the time specified by the quanta expires and if no new quanta value is received, or if a new pause frame with a quanta value set to 0x0000 is received. The MAC also resets `RFC_PAUSE` to zero.

If `ENETn_RCR[FCE]` cleared, the MAC ignores received pause frames.

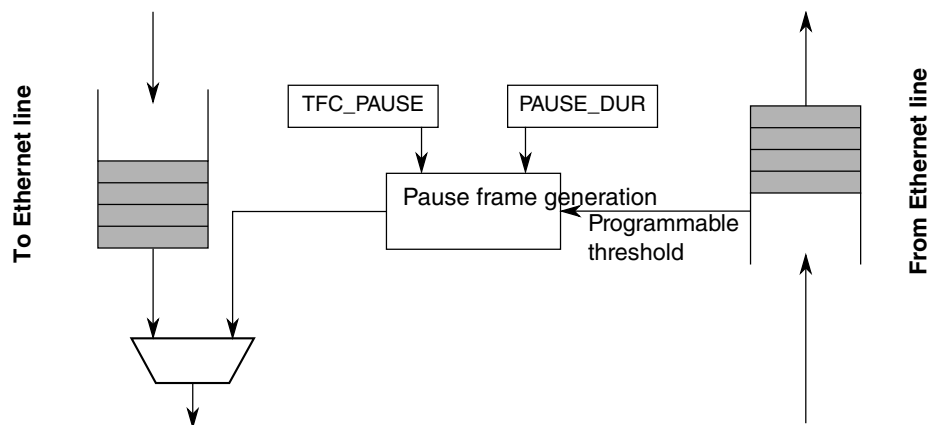

Optionally and independent of `ENETn_RCR[FCE]`, pause frames are forwarded to the client interface if `PAUFWD` is set.

### 40.7.6.2 Local device/FIFO congestion

The MAC transmit engine generates pause frames when the local receive FIFO is not able to receive more than a pre-defined number of words (FIFO programmable threshold) or when pause frame generation is requested by the local host processor.

- To generate a pause frame, the host processor sets ENET $n$ \_TCR[TFC\_PAUSE]. A single pause frame is generated when the current frame transfer is completed and TFC\_PAUSE is automatically cleared. Optionally, an interrupt is generated.
- An XOFF pause frame is generated when the receive FIFO asserts its section empty flag (internal). An XOFF pause frame is generated automatically, when the current frame transfer completes.
- An XON pause frame is generated when the receive FIFO deasserts its section empty flag (internal). An XON pause frame is generated automatically, when the current frame transfer completes.

When an XOFF pause frame is generated, the pause quanta (payload byte P1 and P2) is filled with the value programmed in ENET $n$ \_OPD[PAUSE\_DUR].

**Figure 40-8. Pause frame generation overview**

#### Note

Although the flow control mechanism should prevent any FIFO overflow on the MAC core receive path, the core receive FIFO is protected. When an overflow is detected on the receive FIFO, the current frame is truncated with an error indication set in the frame status word. The frame should subsequently be discarded by the user application.

## 40.7.7 Magic packet detection

Magic packet detection wakes a node that is put in power-down mode by the node management agent. Magic packet detection is supported only if the MAC is configured in sleep mode.

### 40.7.7.1 Sleep mode

To put the MAC in Sleep mode, set ENET $n$ \_ECR[SLEEP]. At the same time ENET $n$ \_ECR[MAGICEN] should also be set to enable magic packet detection.

In addition, if ENET is enabled, write 1 to ENET $n$ \_ECR[SLEEP] before entering into low power mode.

When the MAC is in Sleep mode:

- The transmit logic is disabled.
- The FIFO receive/transmit functions are disabled.
- The receive logic is kept in Normal mode, but it ignores all traffic from the line except magic packets. They are detected so that a remote agent can wake the node.

### 40.7.7.2 Magic packet detection

The core is designed to detect magic packets (see [Magic packets](#)) with the destination address set to:

- Any multicast address
- The broadcast address
- The unicast address programmed in PADDR1/2

When a magic packet is detected, EIR[WAKEUP] is set and none of the statistic registers are incremented.

### 40.7.7.3 Wakeup

When a magic packet is detected, indicated by ENET $n$ \_EIR[WAKEUP], ENET $n$ \_ECR[SLEEP] should be cleared to resume normal operation of the MAC. Clearing the SLEEP bit automatically masks ENET $n$ \_ECR[MAGICEN], disabling magic packet detection.

## 40.7.8 IP accelerator functions

The following sections describe the IP accelerator functions.

### 40.7.8.1 Checksum calculation

The IP and ICMP, TCP, UDP checksums are calculated with one's complement arithmetic summing up 16-bit values.

- For ICMP, the checksum is calculated over the complete ICMP datagram, in other words without IP header.
- For TCP and UDP, the checksums contain the header and data sections and values from the IP header, which can be seen as a pseudo-header that is not actually present in the data stream.

**Table 40-27. IPv4 pseudo-header for checksum calculation**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Source address																															
Destination address																															
Zero				Protocol				TCP/UDP length																							

**Table 40-28. IPv6 pseudo-header for checksum calculation**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Source address																															
Destination address																															
TCP/UDP length																															
Zero												Next header																			

The TCP/UDP length value is the length of the TCP or UDP datagram, which is equal to the payload of an IP datagram. It is derived by subtracting the IP header length from the complete IP datagram length that is given in the IP header (IPv4), or directly taken from the IP header (IPv6). The protocol field is the corresponding value from the IP header. The Zero fields are all zeroes.

For IPv6, the complete 128-bit addresses are considered. The next header value identifies the upper layer protocol as either TCP or UDP. It may differ from the next header value of the IPv6 header if extension headers are inserted before the protocol header.

The checksum calculation uses 16-bit words in network byte order: The first byte sent/received is the MSB, and the second byte sent/received is the LSB of the 16-bit value to add to the checksum. If the frame ends on an odd number of bytes, a zero byte is appended for checksum calculation only, and is not actually transmitted.

### 40.7.8.2 Additional padding processing

According to IEEE 802.3, any Ethernet frame must have a minimum length of 64 octets.

The MAC usually removes padding on receive when a frame with length information is received. Because IP frames have a type value instead of length, the MAC does not remove padding for short IP frames, as it is not aware of the frame contents.

The IP accelerator function can be configured to remove the Ethernet padding bytes that might follow the IP datagram.

On transmit, the MAC automatically adds padding as necessary to fill any frame to a 64-byte length.

### 40.7.8.3 32-bit Ethernet payload alignment

The data FIFOs allow inserting two additional arbitrary bytes in front of a frame. This extends the 14-byte Ethernet header to a 16-byte header, which leads to alignment of the Ethernet payload, following the Ethernet header, on a 32-bit boundary.

This function can be enabled for transmit and receive independently with the corresponding SHIFT16 bits in the ENET<sub>n</sub>\_TACC and ENET<sub>n</sub>\_RACC registers.

When enabled, the valid frame data is arranged as shown in [Table 40-29](#).

**Table 40-29. 64-bit interface data structure with SHIFT16 enabled**

63	56	55	48	47	40	39	32	31	24	23	16	15	8	7	0
----	----	----	----	----	----	----	----	----	----	----	----	----	---	---	---

*Table continues on the next page...*

**Table 40-29. 64-bit interface data structure with SHIFT16 enabled (continued)**

Byte 5	Byte 4	Byte 3	Byte 2	Byte 1	Byte 0	Any value	Any value
Byte 13	Byte 12	Byte 11	Byte 10	Byte 9	Byte 8	Byte 7	Byte 6
...							

#### 40.7.8.3.1 Receive processing

When `ENETn_RACC[SHIFT16]` is set, each frame is received with two additional bytes in front of the frame.

The user application must ignore these first two bytes and find the first byte of the frame in bits 23–16 of the first word from the RX FIFO.

#### Note

SHIFT16 must be set during initialization and kept set during the complete operation, because it influences the FIFO write behavior.

#### 40.7.8.3.2 Transmit processing

When `ENETn_TACC[SHIFT16]` is set, the first two bytes of the first word written (bits 15–0) are discarded immediately by the FIFO write logic.

The SHIFT16 bit can be enabled/disabled for each frame individually if required, but can be changed only between frames.

#### 40.7.8.4 Received frame discard

Because the receive FIFO must be operated in store and forward mode (`ENETn_RSFL` cleared), received frames can be discarded based on the following errors:

- The MAC function receives the frame with an error:
  - The frame has an invalid payload length
  - Frame length is greater than `MAX_FL`
  - Frame received with a CRC-32 error
  - Frame truncated due to receive FIFO overflow
  - Frame is corrupted as PHY signaled an error (`RX_ERR` asserted during reception)

## Functional description

- An IP frame is detected and the IP header checksum is wrong
- An IP frame with a valid IP header and a valid IP header checksum is detected, the protocol is known but the protocol-specific checksum is wrong

If one of the errors occurs and the IP accelerator function is configured to discard frames (ENET $n$ \_RACC), the frame is automatically discarded. Statistics are maintained normally and are not affected by this discard function.

### 40.7.8.5 IPv4 fragments

When an IPv4 IP fragment frame is received, only the IP header is inspected and its checksum verified. 32-bit alignment operates the same way on fragments as it does on normal IP frames, as specified above.

The IP fragment frame payload is not inspected for any protocol headers. As such, a protocol header would only exist in the very first fragment. To assist in protocol-specific checksum verification, the one's-complement sum is calculated on the IP payload (all bytes following the IP header) and provided with the frame status word.

The frame fragment status field (RxBDFRAG) is set to indicate a fragment reception, and the one's-complement sum of the IP payload is available in RxBDPayload checksum].

#### Note

After all fragments have been received and reassembled, the application software can take advantage of the payload checksum delivered with the frame's status word to calculate the protocol-specific checksum of the datagram.

For example, if a TCP payload is delivered by multiple IP fragments, the application software can calculate the pseudo-header checksum value from the first fragment, and add the payload checksums delivered with the status for all fragments to verify the TCP datagram checksum.

### 40.7.8.6 IPv6 support

The following sections describe the IPv6 support.

### 40.7.8.6.1 Receive processing

An Ethernet frame of type 0x86DD identifies an IP Version 6 frame (IPv6) frame. If an IPv6 frame is received, the first IP header is inspected (first ten words), which is available in every IPv6 frame.

If the receive SHIFT16 function is enabled, the IP header is aligned on a 32-bit boundary allowing more efficient processing (see [32-bit Ethernet payload alignment](#)).

For TCP and UDP datagrams, the pseudo-header checksum calculation is performed and verified.

To assist in protocol-specific checksum verification, the one's-complement sum is always calculated on the IP payload (all bytes following the IP header) and provided with the frame status word. For example, if extension headers were present, their sums can be subtracted in software from the checksum to isolate the TCP/UDP datagram checksum, if required.

### 40.7.8.6.2 Transmit processing

For IPv6 transmission, the SHIFT16 function is supported to process 32-bit aligned datagrams.

IPv6 has no IP header checksum; therefore, the IP checksum insertion configuration is ignored.

The protocol checksum is inserted only if the next header of the IP header is a known protocol (TCP, UDP, or ICMP). If a known protocol is detected, the checksum over all bytes following the IP header is calculated and inserted in the correct position.

The pseudo-header checksum calculation is performed for TCP and UDP datagrams accordingly.

## 40.7.9 Resets and stop controls

The following sections describe the resets and stop controls.

### 40.7.9.1 Hardware reset

To reset the Ethernet module, set ENET $n$ \_ECR[RESET].

### 40.7.9.2 Soft reset

When `ENETn_ECR[ETHER_EN]` is cleared during operation, the following occurs:

- uDMA, buffer descriptor, and FIFO control logic are reset, including the buffer descriptor and FIFO pointers.
- A currently ongoing transmit is terminated by asserting TXER to the PHY.
- A currently ongoing transmit FIFO write from the application is terminated by stopping the write to the FIFO, and all further data from the application is ignored. All subsequent writes are ignored until re-enabled.
- A currently ongoing receive FIFO read is terminated. The RxBD has arbitrary values in this case.

### 40.7.9.3 Hardware freeze

When the processor enters debug mode and `ECR[DBGEN]` is set, the MAC enters a freeze state where it stops all transmit and receive activities gracefully.

The following happens when the MAC enters hardware freeze:

- A currently ongoing receive transaction on the receive application interface is completed as normal. No further frames are read from the FIFO.
- A currently ongoing transmit transaction on the transmit application interface is completed as normal (in other words, until writing end-of-packet (EOP)).
- A currently ongoing frame receive is completed normally, after which no further frames are accepted from the MII.
- A currently ongoing frame transmit is completed normally, after which no further frames are transmitted.

### 40.7.9.4 Graceful stop

During a graceful stop, any currently ongoing transactions are completed normally and no further frames are accepted. The MAC can resume from a graceful stop without the need for a reset (for example, clearing `ETHER_EN` is not required).

The following conditions lead to a graceful stop of the MAC transmit or receive datapaths.

#### 40.7.9.4.1 Graceful transmit stop (GTS)

When gracefully stopped, the MAC is no longer reading frame data from the transmit FIFO and has completed any ongoing transmission.

In any of the following conditions, the transmit datapath stops after an ongoing frame transmission has been completed normally.

- ENET $n$ \_TCR[GTS] is set by software.
- ENET $n$ \_TCR[TFC\_PAUSE] is set by software requesting a pause frame transmission. The status (and register bit) is cleared after the pause frame has been sent.
- A pause frame was received stopping the transmitter. The stopped situation is terminated when the pause timer expires or a pause frame with zero quanta is received.
- MAC is placed in Sleep mode by software or the processor entering Stop mode (see [Sleep mode](#)).
- The MAC is in Hardware Freeze mode.

When the transmitter has reached its stopped state, the following events occur:

- The GRA interrupt is asserted, when transitioned into stopped.
- In Hardware Freeze mode, the GRA interrupt does not wait for the application write completion and asserts when the transmit state machine (in other words, line side of TX FIFO) reaches its stopped state.

#### 40.7.9.4.2 Graceful receive stop (GRS)

When gracefully stopped, the MAC is no longer writing frames into the receive FIFO.

The receive datapath stops after any ongoing frame reception has been completed normally, if any of the following conditions occur:

- MAC is placed in Sleep mode either by the software or the processor is in Stop mode). The MAC continues to receive frames and search for magic packets if enabled (see [Magic packet detection](#)). However, no frames are written into the receive FIFO, and therefore are not forwarded to the application.
- The MAC is in Hardware Freeze mode. The MAC does not accept any frames from the MII.

When the receive datapath is stopped, the following events occur:

- If the RX is in the stopped state, RCR[GRS] is set
- The GRA interrupt is asserted when the transmitter and receiver are stopped
- Any ongoing receive transaction to the application (RX FIFO read) continues normally until the frame end of package (EOP) is reached. After this, the following occurs:
  - When Sleep mode is active, all further frames are discarded, flushing the RX FIFO
  - In Hardware Freeze mode, no further frames are delivered to the application and they stay in the receive FIFO.

### **Note**

The assertion of GRS does not wait for an ongoing FIFO read transaction on the application side of the FIFO (FIFO read).

#### **40.7.9.4.3 Graceful stop interrupt (GRA)**

The graceful stopped interrupt (GRA) is asserted for the following conditions:

- In Sleep mode, the interrupt asserts only after both TX and RX datapaths are stopped.
- In Hardware Freeze mode, the interrupt asserts only after both TX and RX datapaths are stopped.
- The MAC transmit datapath is stopped for any other condition (GTS, TFC\_PAUSE, pause received).

The GRA interrupt is triggered only once when the stopped state is entered. If the interrupt is cleared while the stop condition persists, no further interrupt is triggered.

## 40.7.10 IEEE 1588 functions

To allow for IEEE 1588 or similar time synchronization protocol implementations, the MAC is combined with a time-stamping module to support precise time-stamping of incoming and outgoing frames. Set `ENETn_ECR[EN1588]` to enable 1588 support.

Figure 40-9. IEEE 1588 functions overview

### 40.7.10.1 Adjustable timer module

The adjustable timer module (TSM) implements the free-running counter (FRC), which generates the timestamps. The FRC operates with the time-stamping clock, which can be set to any value depending on your system requirements.

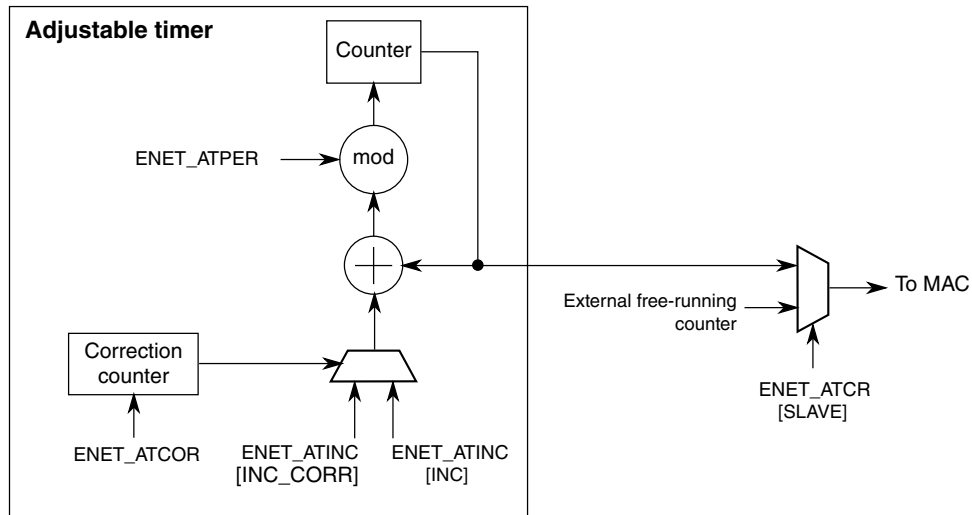

Through dedicated correction logic, the timer can be adjusted to allow synchronization to a remote master and provide a synchronized timing reference to the local system. The timer can be configured to cause an interrupt after a fixed time period, to allow synchronization of software timers or perform other synchronized system functions.

The timer is typically used to implement a period of one second; hence, its value ranges from 0 to  $(1 \times 10^9) - 1$ . The period event can trigger an interrupt, and software can maintain the seconds and hours time values as necessary.

#### 40.7.10.1.1 Adjustable timer implementation

The adjustable timer consists of a programmable counter/accumulator and a correction counter. The periods of both counters and their increment rates are freely configurable, allowing very fine tuning of the timer.

See [Timer Synchronization for Multi-Port Implementations](#), for external clock input options.

**Figure 40-10. Adjustable timer implementation detail**

The counter produces the current time. During each time-stamping clock cycle, a constant value is added to the current time as programmed in ENET<sub>n</sub>\_ATINC. The value depends on the chosen time-stamping clock frequency. For example, if it operates at 125 MHz, setting the increment to eight represents 8 ns.

The period, configured in ENET<sub>n</sub>\_ATPER, defines the modulo when the counter wraps. In a typical implementation, the period is set to  $1 \times 10^9$  so that the counter wraps every second, and hence all timestamps represent the absolute nanoseconds within the one second period. When the period is reached, the counter wraps to start again respecting the period modulo. This means it does not necessarily start from zero, but instead the counter is loaded with the value  $(\text{Current} + \text{Inc} - (1 \times 10^9))$ , assuming the period is set to  $1 \times 10^9$ .

The correction counter operates fully independently, and increments by one with each time-stamping clock cycle. When it reaches the value configured in ENET<sub>n</sub>\_ATCOR, it restarts and instructs the timer once to increment by the correction value, instead of the normal value.

The normal and correction increments are configured in ENET<sub>n</sub>\_ATINC. To speed up the timer, set the correction increment more than the normal increment value. To slow down the timer, set the correction increment less than the normal increment value.

The correction counter only defines the distance of the corrective actions, not the amount. This allows very fine corrections and low jitter (in the range of 1 ns) independent of the chosen clock frequency.

By enabling slave mode ( $\text{ENET}_n\text{\_ATCR}[\text{SLAVE}] = 1$ ), the timer is ignored and the current time is externally provided from one of the external modules. See the Chip Configuration details for which clock source is used. This is useful if multiple modules within the system must operate from a single timer (see [Timer Synchronization for Multi-Port Implementations](#)). When slave mode is enabled, you still must set  $\text{ENET}_n\text{\_ATINC}[\text{INC}]$  to the value of the master, since it is used for internal comparisons.

### 40.7.10.2 Timer Synchronization for Multi-Port Implementations

Additional inputs are available to provide a timer value for all time-stamping functions. This is necessary to synchronize the two MACs to a single reference timer. See the Chip Configuration details for available clock inputs to the time-stamping functions. To operate the MAC in slave mode,  $\text{ENET}_n\text{\_ATCR}[\text{SLAVE}]$  disables the internal adjustable timer and uses the externally provided timer.

### 40.7.10.3 Transmit timestamping

Only 1588 event frames need to be time-stamped on transmit. The client application (for example, the MAC driver) should detect 1588 event frames and set  $\text{TxBd}[\text{TS}]$  together with the frame.

If  $\text{TxBd}[\text{TS}]$  is set, the MAC records the timestamp for the frame in  $\text{ENET}_n\text{\_ATSTMP}$ .  $\text{ENET}_n\text{\_EIR}[\text{TS\_AVAIL}]$  is set to indicate that a new timestamp is available.

Software implements a handshaking procedure by setting  $\text{TxBd}[\text{TS}]$  when it transmits the frame for which a timestamp is needed, and then waits for  $\text{ENET}_n\text{\_EIR}[\text{TS\_AVAIL}]$  to determine when the timestamp is available. The timestamp is then read from  $\text{ENET}_n\text{\_ATSTMP}$ . This is done for all event frames. Other frames do not use  $\text{TxBd}[\text{TS}]$  and, therefore, do not interfere with the timestamp capture.

### 40.7.10.4 Receive timestamping

When a frame is received, the MAC latches the value of the timer when the frame's start of frame delimiter (SFD) field is detected, and provides the captured timestamp on  $\text{RxBd}[1588 \text{ timestamp}]$ . This is done for all received frames.

### 40.7.10.5 Time synchronization

The adjustable timer module is available to synchronize the local clock of a node to a remote master. It implements a free running 32-bit counter, and also contains an additional correction counter.

The correction counter increases or decreases the rate of the free running counter, enabling very fine granular changes of the timer for synchronization, yet adding only very low jitter when performing corrections.

The application software implements, in a slave scenario, the required control algorithm, setting the correction to compensate for local oscillator drifts and locking the timer to the remote master clock on the network.

The timer and all timestamp-related information should be configured to show the true nanoseconds value of a second (in other words, the timer is configured to have a period of one second). Hence, the values range from 0 to  $(1 \times 10^9) - 1$ . In this application, the seconds counter is implemented in software using an interrupt function that is executed when the nanoseconds counter wraps at  $1 \times 10^9$ .

### 40.7.10.6 Input Capture and Output Compare

The Input Capture Output Compare block can be used to provide precise hardware timing for input and output events.

#### 40.7.10.6.1 Input capture

The  $TCCR_n$  capture registers latch the time value when the corresponding external event occurs. An event can be a rising-, falling-, or either-edge of one of the  $1588\_TMR_n$  signals. An event will cause the corresponding  $TCSR_n[TF]$  timer flag to be set, indicating that an input capture has occurred. If the corresponding interrupt is enabled with the  $TCSR_n[TIE]$  field, an interrupt can be generated.

#### 40.7.10.6.2 Output compare

The  $TCCR_n$  compare registers are loaded with the time at which the corresponding event should occur. When the ENET free-running counter value matches the output compare reference value in the  $TCCR_n$  register, the corresponding flag,  $TCSR_n[TF]$ , is set, indicating that an output compare has occurred. The corresponding interrupt, if enabled by  $TCSR_n[TIE]$ , will be generated. The corresponding  $1588\_TMR_n$  output signal will be asserted according to  $TCSR_n[TMODE]$ .

**NOTE**

If  $TCSR_n[TMODE]$  is set to 10X1b or 1010b then the timer output pin toggle-on-overflow will occur only when PINPER, PEREN, and EN bits of the ATCR register are one.

**40.7.10.6.3 DMA requests**

A DMA request can be enabled by setting  $TCSR_n[TDRE]$ . The corresponding DMA request is generated when the  $TCSR_n[TF]$  timer flag is set. When the DMA has completed, the corresponding  $TCSR_n[TF]$  flag is cleared.

**40.7.11 FIFO thresholds**

The core FIFO thresholds are fully programmable to dynamically change the FIFO operation.

For example, store and forward transfer can be enabled by a simple change in the FIFO threshold registers.

The thresholds are defined in 64-bit words.

The receive and transmit FIFOs both have a depth of 256 words.

**40.7.11.1 Receive FIFO**

Four programmable thresholds are available, which can be set to any value to control the core operation as follows.

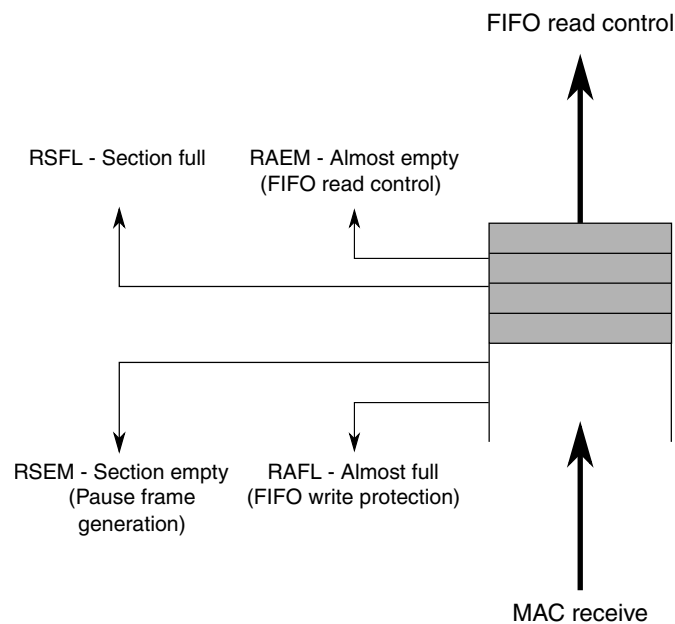

**Table 40-30. Receive FIFO thresholds definition**

Register	Description
$ENET_n\_RSFL$ [RX_SECTION_F ULL]	<p>When the FIFO level reaches the <math>ENET_n\_RSFL</math> value, the MAC status signal is asserted to indicate that data is available in the receive FIFO (cut-through operation). Once asserted, if the FIFO empties below the threshold set with <math>ENET_n\_RAEM</math> and if the end-of-frame is not yet stored in the FIFO, the status signal is deasserted again.</p> <p>If a frame has a size smaller than the threshold (in other words, an end-of-frame is available for the frame), the status is also asserted.</p> <p>To enable store and forward on the receive path, clear <math>ENET_n\_RSFL</math>. The MAC status signal is asserted only when a complete frame is stored in the receive FIFO.</p> <p>When programming a non-zero value to <math>ENET_n\_RSFL</math> (cut-through operation) it should be greater than <math>ENET_n\_RAEM</math>.</p>
$ENET_n\_RAEM$	<p>When the FIFO level reaches the <math>ENET_n\_RAEM</math> value, and the end-of-frame has not been received, the core receive read control stops the FIFO read (and subsequently stops transferring data to the MAC client application).</p>

*Table continues on the next page...*

**Table 40-30. Receive FIFO thresholds definition (continued)**

Register	Description
[RX_ALMOST_EMPTY]	It continues to deliver the frame, if again more data than the threshold or the end-of-frame is available in the FIFO. Set ENETn_RAEM to a minimum of six.
ENETn_RAFL [RX_ALMOST_FULL]	When the FIFO level approaches the maximum and there is no more space remaining for at least ENETn_RAFL number of words, the MAC control logic stops writing data in the FIFO and truncates the receive frame to avoid FIFO overflow. The corresponding error status is set when the frame is delivered to the application. Set ENETn_RAFL to a minimum of 4.
ENETn_RSEM [RX_SECTION_EMPTY]	When the FIFO level reaches the ENETn_RSEM value, an indication is sent to the MAC transmit logic, which generates an XOFF pause frame. This indicates FIFO congestion to the remote Ethernet client. When the FIFO level goes below the value programmed in ENETn_RSEM, an indication is sent to the MAC transmit logic, which generates an XON pause frame. This indicates the FIFO congestion is cleared to the remote Ethernet client. Clearing ENETn_RSEM disables any pause frame generation.

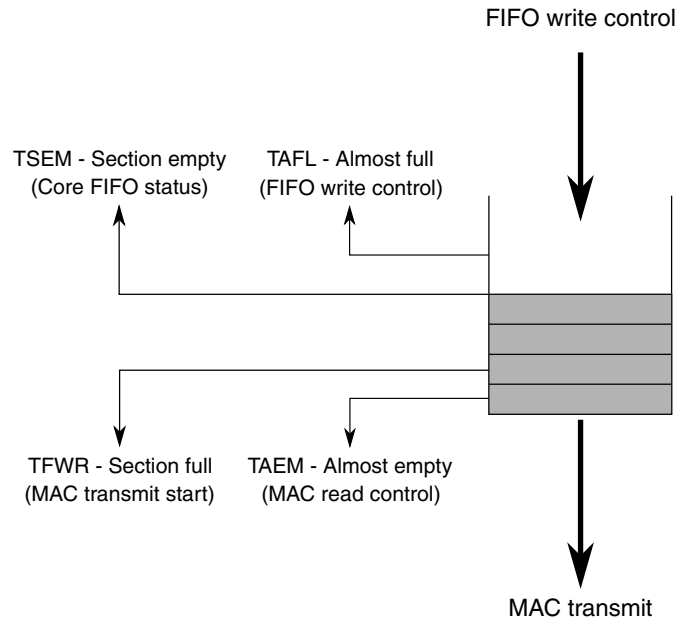

**Figure 40-11. Receive FIFO overview**

### 40.7.11.2 Transmit FIFO

Four programmable thresholds are available which control the core operation as described below.

**Table 40-31. Transmit FIFO thresholds definition**

Register	Description
ENET <sub>n</sub> _TAEM [TX_ALMOST_EMPTY]	When the FIFO level reaches the ENET <sub>n</sub> _TAEM value and no end-of-frame is available for the frame, the MAC transmit logic avoids a FIFO underflow by stopping FIFO reads and transmitting the Ethernet frame with an MII error indication.  Set ENET <sub>n</sub> _TAEM to a minimum of 4.
ENET <sub>n</sub> _TAFL [TX_ALMOST_FULL]	When the FIFO level approaches the maximum, so that there is no more space for at least ENET <sub>n</sub> _TAFL number of words, the MAC deasserts its control signal to the application.  If the application does not react on this signal, the FIFO write control logic avoids FIFO overflow by truncating the current frame and setting the error status. As a result, the frame is transmitted with an MII error indication.  Set ENET <sub>n</sub> _TAFL to a minimum of 4. Larger values allow more latency for the application to react on the MAC control signal deassertion, before the frame is truncated. A typical setting is 8, which offers 3–4 clock cycles of latency to the application to react on the MAC control signal deassertion.
ENET <sub>n</sub> _TSEM [TX_SECTION_EMPTY]	When the FIFO level reaches the ENET <sub>n</sub> _TSEM value, a MAC status signal is deasserted to indicate that the transmit FIFO is getting full. This gives the ENET module an indication to slow or stop its write transaction to avoid a buffer overflow. This is a pure indication function to the application. It has no effect within the MAC.  When ENET <sub>n</sub> _TSEM is 0, the signal is never deasserted.
ENET <sub>n</sub> _TFWR	When the FIFO level reaches the ENET <sub>n</sub> _TFWR value and when STRFWD is cleared, the MAC transmit control logic starts frame transmission before the end-of-frame is available in the FIFO (cut-through operation).  If a complete frame has a size smaller than the ENET <sub>n</sub> _TFWR threshold, the MAC also transmits the frame to the line.  To enable store and forward on the transmit path, set STRFWD. In this case, the MAC starts to transmit data only when a complete frame is stored in the transmit FIFO.

**Figure 40-12. Transmit FIFO overview**

### 40.7.12 Loopback options

The core implements external and internal loopback options, which are controlled by the ENET<sub>n</sub>\_RCR register fields found here.

The core implements external and internal loopback options, which are controlled by the following ENET<sub>n</sub>\_RCR register fields:

**Table 40-32. Loopback options**

Register field	Description
LOOP	Internal MII loopback. The MAC transmit is returned to the MAC receive. No data is transmitted to the external interfaces.  In MII internal loopback, MII_TXCLK and MII_RXCLK must be provided with a clock signal (2.5 MHz for 10 Mbit/s, and 25 MHz for 100 Mbit/s))

**Figure 40-13. Loopback options**

### 40.7.13 Legacy buffer descriptors

To support the Ethernet controller on previous chips, legacy FEC buffer descriptors are available. To enable legacy support, write 0 to ENET<sub>n</sub>\_ECR[1588EN].

**NOTE**

- The legacy buffer descriptor tables show the byte order for little-endian chips. **DBSWP** must be set to 1 after reset to enable little-endian mode.

### 40.7.13.1 Legacy receive buffer descriptor

The following table shows the legacy FEC receive buffer descriptor. [Table 40-36](#) contains the descriptions for each field.

**Table 40-33. Legacy FEC receive buffer descriptor (RxBD)**

	Byte 1								Byte 0							
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Offset + 0	Data length															
Offset + 2	E	RO1	W	RO2	L	—	—	M	BC	MC	LG	NO	—	CR	OV	TR
Offset + 4	Rx data buffer pointer — low halfword															
Offset + 6	Rx data buffer pointer — high halfword															

### 40.7.13.2 Legacy transmit buffer descriptor

The following table shows the legacy FEC transmit buffer descriptor. [Table 40-38](#) contains the descriptions for each field.

**Table 40-34. Legacy FEC transmit buffer descriptor (TxBD)**

	Byte 1								Byte 0							
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Offset + 0	Data Length															
Offset + 2	R	TO1	W	TO2	L	TC	ABC <sup>1</sup>	—	—	—	—	—	—	—	—	—
Offset + 4	Tx Data Buffer Pointer — low halfword															
Offset + 6	Tx Data Buffer Pointer — high halfword															

1. This field is not supported by the uDMA.

## 40.7.14 Enhanced buffer descriptors

This section provides a description of the enhanced operation of the driver/uDMA via the buffer descriptors.

It is followed by a detailed description of the receive and transmit descriptor fields. To enable the enhanced features, set ENET $n$ \_ECR[1588EN].

### NOTE

The enhanced buffer descriptor tables show the byte order for little-endian chips. [DBSWP](#) must be set to 1 after reset to enable little-endian mode.

### 40.7.14.1 Enhanced receive buffer descriptor

The following table shows the enhanced uDMA receive buffer descriptor. [Table 40-36](#) contains the descriptions for each field.

**Table 40-35. Enhanced uDMA receive buffer descriptor (RxB D)**

	Byte 1								Byte 0							
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Offset + 0	Data length

Offset + 1E	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

**Table 40-36. Receive buffer descriptor field definitions**

Word	Field	Description
Offset + 0	15–0 Data Length	Data length. Written by the MAC. Data length is the number of octets written by the MAC into this BD's data buffer if L is cleared (the value is equal to EMRBR), or the length of the frame including CRC if L is set. It is written by the MAC once as the BD is closed.
Offset + 2	15 E	Empty. Written by the MAC (= 0) and user (= 1). 0 The data buffer associated with this BD is filled with received data, or data reception has aborted due to an error condition. The status and length fields have been updated as required. 1 The data buffer associated with this BD is empty, or reception is currently in progress.
Offset + 2	14 RO1	Receive software ownership. This field is reserved for use by software. This read/write field is not modified by hardware, nor does its value affect hardware.
Offset + 2	13 W	Wrap. Written by user. 0 The next buffer descriptor is found in the consecutive location. 1 The next buffer descriptor is found at the location defined in ENETn_RDSR.

Table continues on the next page...

**Table 40-36. Receive buffer descriptor field definitions (continued)**

Word	Field	Description
Offset + 2	12 RO2	Receive software ownership. This field is reserved for use by software. This read/write field is not modified by hardware, nor does its value affect hardware.
Offset + 2	11 L	Last in frame. Written by the uDMA. 0 The buffer is not the last in a frame. 1 The buffer is the last in a frame.
Offset + 2	10–9	Reserved, must be cleared.
Offset + 2	8 M	Miss. Written by the MAC. This field is set by the MAC for frames accepted in promiscuous mode, but flagged as a miss by the internal address recognition. Therefore, while in promiscuous mode, you can use this field to quickly determine whether the frame was destined to this station. This field is valid only if the L and PROM bits are set. 0 The frame was received because of an address recognition hit. 1 The frame was received because of promiscuous mode. The information needed for this field comes from the promiscuous_miss(ff_rx_err_stat[26]) sideband signal.
Offset + 2	7 BC	Set if the DA is broadcast (FFFF_FFFF_FFFF).
Offset + 2	6 MC	Set if the DA is multicast and not BC.
Offset + 2	5 LG	Receive frame length violation. Written by the MAC. A frame length greater than RCR[MAX_FL] was recognized. This field is valid only if the L field is set. The receive data is not altered in any way unless the length exceeds TRUNC_FL bytes.
Offset + 2	4 NO	Receive non-octet aligned frame. Written by the MAC. A frame that contained a number of bits not divisible by 8 was received, and the CRC check that occurred at the preceding byte boundary generated an error or a PHY error occurred. This field is valid only if the L field is set. If this field is set, the CR field is not set.
Offset + 2	3	Reserved, must be cleared.
Offset + 2	2 CR	Receive CRC or frame error. Written by the MAC. This frame contains a PHY or CRC error and is an integral number of octets in length. This field is valid only if the L field is set.
Offset + 2	1 OV	Overflow. Written by the MAC. A receive FIFO overrun occurred during frame reception. If this field is set, the other status fields, M, LG, NO, and CR, lose their normal meaning and are zero. This field is valid only if the L field is set.
Offset + 2	0 TR	Set if the receive frame is truncated (frame length >TRUNC_FL). If the TR field is set, the frame must be discarded and the other error fields must be ignored because they may be incorrect.
Offset + 4	15–0 Data buffer pointer low	Receive data buffer pointer, low halfword
Offset + 6	15–0 Data buffer pointer high	Receive data buffer pointer, high halfword <sup>1</sup>
Offset + 8	15–13 VPCP	VLAN priority code point. This field is written by the uDMA to indicate the frame priority level. Valid values are from 0 (best effort) to 7 (highest). This value can be used to prioritize different classes of traffic (e.g., voice, video, data). This field is only valid if the L field is set.

*Table continues on the next page...*

**Table 40-36. Receive buffer descriptor field definitions (continued)**

Word	Field	Description
Offset + 8	12–6	Reserved, must be cleared.
Offset + 8	5 ICE	IP header checksum error. This is an accelerator option. This field is written by the uDMA. Set when either a non-IP frame is received or the IP header checksum was invalid. An IP frame with less than 3 bytes of payload is considered to be an invalid IP frame. This field is only valid if the L field is set.
Offset + 8	4 PCR	Protocol checksum error. This is an accelerator option. This field is written by the uDMA. Set when the checksum of the protocol is invalid or an unknown protocol is found and checksumming could not be performed. This field is only valid if the L field is set.
Offset + 8	3	Reserved, must be cleared.
Offset + 8	2 VLAN	VLAN. This is an accelerator option. This field is written by the uDMA. It means that the frame has a VLAN tag. This field is valid only if the L field is set.
Offset + 8	1 IPV6	IPV6 Frame. This field is written by the uDMA. This field indicates that the frame has an IPv6 frame type. If this field is not set it means that an IPv4 or other protocol frame was received. This field is valid only if the L field is set.
Offset + 8	0 FRAG	IPv4 Fragment. This is an accelerator option. This field is written by the uDMA. It indicates that the frame is an IPv4 fragment frame. This field is only valid when the L field is set.
Offset + A	15 ME	MAC error. This field is written by the uDMA. This field means that the frame stored in the system memory was received with an error (typically, a receive FIFO overflow). This field is only valid when the L field is set.
Offset + A	14–11	Reserved, must be cleared.
Offset + A	10 PE	PHY Error. This field is written by the uDMA. Set to "1" when the frame was received with an Error character on the PHY interface. The frame is invalid. This field is valid only when the L field is set.
Offset + A	9 CE	Collision. This field is written by the uDMA. Set when the frame was received with a collision detected during reception. The frame is invalid and sent to the user application. This field is valid only when the L field is set.
Offset + A	8 UC	Unicast. This field is written by the uDMA, and means that the frame is unicast. This field is valid regardless of whether the L field is set.
Offset + A	7 INT	Generate RXB/RXF interrupt. This field is set by the user to indicate that the uDMA is to generate an interrupt on the <i>dma_int_rxb / dma_int_rxfevent</i> .
Offset + A	6–0	Reserved, must be cleared.
Offset + C	15–0 Payload checksum	Internet payload checksum. This is an accelerator option. It is the one's complement sum of the payload section of the IP frame. The sum is calculated over all data following the IP header until the end of the IP payload. This field is valid only when the L field is set.
Offset + E	15–11 Header length	Header length. This is an accelerator option. This field is written by the uDMA. This field is the sum of 32-bit words found within the IP and its following protocol headers. If an IP datagram with an unknown protocol is found, then the value is the length of the IP header. If no IP frame or an erroneous IP header is found, the value is 0. The following values are minimum values if no header options exist in the respective headers: <ul style="list-style-type: none"> <li>• ICMP/IP: 6 (5 IP header, 1 ICMP header)</li> <li>• UDP/IP: 7 (5 IP header, 2 UDP header)</li> <li>• TCP/IP: 10 (5 IP header, 5 TCP header)</li> </ul> <p>This field is only valid if the L field is set.</p>

Table continues on the next page...

**Table 40-36. Receive buffer descriptor field definitions (continued)**

Word	Field	Description
Offset + E	10–8	Reserved, must be cleared.
Offset + E	7–0 Protocol type	Protocol type. This is an accelerator option. The 8-bit protocol field found within the IP header of the frame. It is valid only when ICE is cleared. This field is valid only when the L field is set.
Offset + 10	15–0	Reserved, must be cleared.
Offset + 12	15 BDU	Last buffer descriptor update done. Indicates that the last BD data has been updated by uDMA. This field is written by the user (=0) and uDMA (=1).
Offset + 12	14–0	Reserved, must be cleared.
Offset + 14	15–0	This value is written by the uDMA. It is only valid if the L field is set.
Offset + 16	1588 timestamp	
Offset + 18 – Offset + 1E	15–0	Reserved, must be cleared.

- The receive buffer pointer, containing the address of the associated data buffer, must always be evenly divisible by 64. The buffer must reside in memory external to the MAC. The Ethernet controller never modifies this value.

#### 40.7.14.2 Enhanced transmit buffer descriptor

**Table 40-37. Enhanced transmit buffer descriptor (TxBD)**

	Byte 1								Byte 0							
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Offset + 0	Data length															
Offset + 2	R	TO1	W	TO2	L	TC	—	—	—	—	—	—	—	—	—	—
Offset + 4	Tx Data Buffer Pointer – low halfword															
Offset + 6	Tx Data Buffer Pointer – high halfword															
Offset + 8	TXE	—	UE	EE	FE	LCE	OE	TSE	—	—	—	—	—	—	—	—
Offset + A	—	INT	TS	PINS	IINS	—	—	—	—	—	—	—	—	—	—	—
Offset + C	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Offset + E	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Offset + 10	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Offset + 12	BDU	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Offset + 14	1588 timestamp – low halfword															
Offset + 16	1588 timestamp – high halfword															
Offset + 18	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Offset + 1A	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Offset + 1C	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Offset + 1E	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

**Table 40-38. Enhanced transmit buffer descriptor field definitions**

Word	Field	Description
Offset + 0	15–0 Data Length	Data length, written by user. Data length is the number of octets the MAC should transmit from this BD's data buffer. It is never modified by the MAC.
Offset + 2	15 R	Ready. Written by the MAC and you. 0 The data buffer associated with this BD is not ready for transmission. You are free to manipulate this BD or its associated data buffer. The MAC clears this field after the buffer has been transmitted or after an error condition is encountered. 1 The data buffer, prepared for transmission by you, has not been transmitted or currently transmits. You may write no fields of this BD after this field is set.
Offset + 2	14 TO1	Transmit software ownership. This field is reserved for software use. This read/write field is not modified by hardware and its value does not affect hardware.
Offset + 2	13 W	Wrap. Written by user. 0 The next buffer descriptor is found in the consecutive location 1 The next buffer descriptor is found at the location defined in ETDSR.
Offset + 2	12 TO2	Transmit software ownership. This field is reserved for use by software. This read/write field is not modified by hardware and its value does not affect hardware.
Offset + 2	11 L	Last in frame. Written by user. 0 The buffer is not the last in the transmit frame 1 The buffer is the last in the transmit frame
Offset + 2	10 TC	Transmit CRC. Written by user, and valid only when L is set. 0 End transmission immediately after the last data byte 1 Transmit the CRC sequence after the last data byte This field is valid only when the L field is set.
Offset + 2	9 ABC	Append bad CRC. <b>Note:</b> This field is not supported by the uDMA and is ignored.
Offset + 2	8–0	Reserved, must be cleared.
Offset + 4	15–0 Data buffer pointer low	Tx data buffer pointer, low halfword
Offset + 6	15–0 Data buffer pointer high	Tx data buffer pointer, high halfword. The buffer must reside in memory external to the MAC. This value is never modified by the Ethernet controller. <b>NOTE:</b> For optimal performance, make the transmit buffer pointer evenly divisible by 64.
Offset + 8	15 TXE	Transmit error occurred. This field is written by the uDMA. This field indicates that there was a transmit error of some sort reported with the frame. Effectively this field is an OR of the other error fields including UE, EE, FE, LCE, OE, and TSE. This field is valid only when the L field is set.
Offset + 8	14	Reserved, must be cleared.
Offset + 8	13 UE	Underflow error. This field is written by the uDMA. This field indicates that the MAC reported an underflow error on transmit. This field is valid only when the L field is set.

*Table continues on the next page...*

**Table 40-38. Enhanced transmit buffer descriptor field definitions (continued)**

Word	Field	Description
Offset + 8	12 EE	Excess Collision error. This field is written by the uDMA. This field indicates that the MAC reported an excess collision error on transmit. This field is valid only when the L field is set.
Offset + 8	11 FE	Frame with error. This field is written by the uDMA. This field indicates that the MAC reported that the uDMA reported an error when providing the packet. This field is valid only when the L field is set.
Offset + 8	10 LCE	Late collision error. This field is written by the uDMA. This field indicates that the MAC reported that there was a Late Collision on transmit. This field is valid only when the L field is set.
Offset + 8	9 OE	Overflow error. This field is written by the uDMA. This field indicates that the MAC reported that there was a FIFO overflow condition on transmit. This field is only valid when the L field is set.
Offset + 8	8 TSE	Timestamp error. This field is written by the uDMA. This field indicates that the MAC reported a different frame type than a timestamp frame. This field is valid only when the L field is set.
Offset + 8	7–0	Reserved, must be cleared.
Offset + A	15	Reserved, must be cleared.
Offset + A	14 INT	Generate interrupt flags. This field is written by the user. This field is valid regardless of the L field and must be the same for all EBD for a given frame. The uDMA does not update this value.
Offset + A	13 TS	Timestamp. This field is written by the user. This indicates that the uDMA is to generate a timestamp frame to the MAC. This field is valid regardless of the L field and must be the same for all EBD for the given frame. The uDMA does not update this value.
Offset + A	12 PINS	Insert protocol specific checksum. This field is written by the user. If set, the MAC's IP accelerator calculates the protocol checksum and overwrites the corresponding checksum field with the calculated value. The checksum field must be cleared by the application generating the frame. The uDMA does not update this value. This field is valid regardless of the L field and must be the same for all EBD for a given frame.
Offset + A	11 IINS	Insert IP header checksum. This field is written by the user. If set, the MAC's IP accelerator calculates the IP header checksum and overwrites the corresponding header field with the calculated value. The checksum field must be cleared by the application generating the frame. The uDMA does not update this value. This field is valid regardless of the L field and must be the same for all EBD for a given frame.
Offset + A	10–0	Reserved, must be cleared.
Offset + C	15–0	Reserved, must be cleared.
Offset + E	15–0	Reserved, must be cleared.
Offset + 10	15–0	Reserved, must be cleared.
Offset + 12	15 BDU	Last buffer descriptor update done. Indicates that the last BD data has been updated by uDMA. This field is written by the user (=0) and uDMA (=1).
Offset + 12	14–0	Reserved, must be cleared.
Offset + 14	15–0	This value is written by the uDMA . It is valid only when the L field is set.
Offset + 16	1588 timestamp	
Offset + 18–Offset + 1E	15–0	Reserved, must be cleared.

## 40.7.15 Client FIFO application interface

The FIFO interface is completely asynchronous from the Ethernet line, and the transmit and receive interface can operate at a different clock rate.

All transfers to/from the user application are handled independently of the core operation, and the core provides a simple interface to user applications based on a two-signal handshake.

### 40.7.15.1 Data structure description

The data structure defined in the following tables for the FIFO interface must be respected to ensure proper data transmission on the Ethernet line. Byte 0 is sent to and received from the line first.

**Table 40-39. FIFO interface data structure**

	63	56 55	48 47	40 39	32 31	24 23	16 15	8 7	0
Word 0	Byte 7	Byte 6	Byte 5	Byte 4	Byte 3	Byte 2	Byte 1	Byte 0	
Word 1	Byte 15	Byte 14	Byte 13	Byte 12	Byte 11	Byte 10	Byte 9	Byte 8	
...	...								

The size of a frame on the FIFO interface may not be a modulo of 64-bit.

The user application may not care about the Ethernet frame formats in full detail. It needs to provide and receive an Ethernet frame with the following structure:

- Ethernet MAC destination address
- Ethernet MAC source address
- Optional 802.1q VLAN tag (VLAN type and info field)
- Ethernet length/type field
- Payload

Frames on the FIFO interface do not contain preamble and SFD fields, which are inserted and discarded by the MAC on transmit and receive, respectively.

- On receive, CRC and frame padding can be stripped or passed through transparently.
- On transmit, padding and CRC can be provided by the user application, or appended automatically by the MAC independently for each frame. No size restrictions apply.

### Note

On transmit, if ENET $n$ \_TCR[ADDINS] is set, bytes 6–11 of each frame can be set to any value, since the MAC overwrites the bytes with the MAC address programmed in the ENET $n$ \_PAUR and ENET $n$ \_PALR registers.

**Table 40-40. FIFO interface frame format**

Byte number	Field
0–5	Destination MAC address
6–11	Source MAC address
12–13	Length/type field
14–N	Payload data

VLAN-tagged frames are supported on both transmit and receive, and implement additional information (VLAN type and info).

**Table 40-41. FIFO interface VLAN frame format**

Byte number	Field
0–5	Destination MAC address
6–11	Source MAC address
12–15	VLAN tag and info
16–17	Length/type field
18–N	Payload data

### Note

The standard defines that the LSB of the MAC address is sent/received first, while for all the other header fields — in other words, length/type, VLAN tag, VLAN info, and pause quanta — the MSB is sent/received first.

## 40.7.15.2 Data structure examples

## Functional description

**Figure 40-14. Normal Ethernet frame 64-bit mapping example**

**Figure 40-15. VLAN-tagged frame 64-bit mapping example**

If CRC forwarding is enabled (CRCFWD = 0), the last four valid octets of the frame contain the FCS field. The non-significant bytes of the last word can have any value.

### 40.7.15.3 Frame status

A MAC layer status word and an accelerator status word is available in the receive buffer descriptor.

See [Enhanced buffer descriptors](#) for details.

The status is available with each frame with the last data of the frame.

If the frame status contains a MAC layer error (for example, CRC or length error), RxB[ME] is also set with the last data of the frame.

## 40.7.16 FIFO protection

The following sections describe the FIFO protection mechanisms.

### 40.7.16.1 Transmit FIFO underflow

During a frame transfer, when the transmit FIFO reaches the almost empty threshold with no end-of-frame indication stored in the FIFO, the MAC logic:

- Stops reading data from the FIFO
- Asserts the MII error signal (MII\_TXER) (1 in Figure 40-16) to indicate that the fragment already transferred is not valid
- Deasserts the MII transmit enable signal (MII\_TXEN) to terminate the frame transfer (2)

After an underflow, when the application completes the frame transfer (3), the MAC transmit logic discards any new data available in the FIFO until the end of packet is reached (4) and sets the enhanced TxBD[UE] field.

The MAC starts to transfer data on the MII interface when the application sends a new frame with a start of frame indication (5).

Figure 40-16. Transmit FIFO underflow protection

### 40.7.16.2 Transmit FIFO overflow

On the transmit path, when the FIFO reaches the programmable almost full threshold, the internal MAC ready signal is deasserted. The application should stop sending new data.

However, if the application keeps sending data, the transmit FIFO overflows, corrupting contents that were previously stored. The core logic sets the enhanced TxBD[OE] field for the next frame transmitted to indicate this overflow occurrence.

#### Note

Overflow is a fatal error and must be addressed by resetting the core or clearing ENET $_n$ \_ECR[ETHER\_EN], to clear the FIFOs and prepare for normal operation again.

### 40.7.16.3 Receive FIFO overflow

During a frame reception, if the client application is not able to receive data (1), the MAC receive control truncates the incoming frame when the FIFO reaches the programmable almost-full threshold to avoid an overflow.

The frame is subsequently received on the FIFO interface with an error indication (enhanced RxBD[ME] field set together with receive end-of-packet) (2) with the truncation error status field set (3).

Figure 40-17. Receive FIFO overflow protection

## 40.7.17 PHY management interface

The MDIO interface is a two-wire management interface. The MDIO management interface implements a standardized method to access the PHY device management registers.

The core implements a master MDIO interface, which can be connected to up to 32 PHY devices.

### 40.7.17.1 MDIO clause 22 frame format

The core MDIO master controller communicates with the slave (PHY device) using frames that are defined in the following table.

A complete frame has a length of 64 bits made up of an optional 32-bit preamble, 14-bit command, 2-bit bus direction change, and 16-bit data. Each bit is transferred on the rising edge of the MDIO clock (MDC signal). The MDIO data signal is tri-stated between frames.

The core PHY management interface supports the standard MDIO specification (IEEE 802.3 Clause 22).

**Table 40-42. MDIO clause 22 frame structure**

ST	OP	PHYADR	REGADR	TA	DATA
----	----	--------	--------	----	------

**Table 40-43. MDIO frame field descriptions**

Field	Description
ST (2 bits)	Start indication field, programmed with ENET $n$ _MMFR[ST] and equal to 01 for Standard MDIO (Clause 22).
OP (2 bits)	Opcode defines type of operation. Programmed with ENET $n$ _MMFR[OP]. 01 Write operation 10 Read operation
PHYADR (5 bits)	Five-bit PHY device address, programmed with ENET $n$ _MMFR[PA]. Up to 32 devices can be addressed.
REGADR (5 bits)	Five-bit register address, programmed with ENET $n$ _MMFR[RA]. Each PHY can implement up to 32 registers.
TA (2 bits)	Turnaround time, programmed with ENET $n$ _MMFR[TA]. Two bit-times are reserved for read operations to switch the data bus from write to read. The PHY device presents its register contents in the data phase and drives the bus from the second bit of the turnaround phase.
Data	Data, set by ENET $n$ _MMFR[DATA]. Written to or read from the PHY

**Table 40-43. MDIO frame field descriptions**

Field	Description
(16 bits)	

### 40.7.17.2 MDIO clause 45 frame format

The extended MDIO frame structure defined in IEEE 802.3 Clause 45 introduces indirect addressing. First, a write transaction to an address register is done, followed by a write or read transaction which will put the 16-bit data in the register or retrieve the register contents respectively. A preamble of 32 bits of logical ones is sent prior to every transaction. The MDIO data signal is tri-stated between frames.

The extended MDIO defines four transactions, which are determined by the two-bit opcode field.

**Table 40-44. MDIO clause 45 frame structure**

ST	OP	PRTAD	DEVAD	TA	ADDR/DATA

All bits are transmitted from left to right (Preamble bits first) and all fields have their Most-Significant bit sent first (leftmost in above table). The complete frame has a length of 64 bits (32-bit preamble, 14-bit command, 2-bit bus direction change, 16-bit data). Each bit is transferred with the rising edge of the MDIO clock (MDC).

The fields and transactions are summarized in the following tables.

**Table 40-45. MDIO clause 45 frame field descriptions**

Field	Description
ST	Start indication. Indicates the end of the preamble and start of the frame. This value is 00 for extended MDIO (Clause 45) frames.
OP	Opcode defines if a read or write operation is performed and is programmed with ENET $n$ _MMFR[OP]. See <a href="#">Table 40-46</a> for more information. 00 Address write 01 Write operation 10 Read inc. operation 11 Read operation
PRTAD	The port address specifies a MDIO port. Each Port can have up to 32 devices which each can have a separate set of registers.
DEVAD	Device address. Up to 32 devices can be addressed (within a port).
TA	Turnaround time, programmed with ENET $n$ _MMFR[TA]. Two bit-times are reserved for read operations to switch the data bus from write to read. The PHY device presents its register contents in the data phase and drives the bus from the second bit of the turnaround phase.

*Table continues on the next page...*

**Table 40-45. MDIO clause 45 frame field descriptions (continued)**

Field	Description
ADDR/DATA	16-bit address (for address write) or data, set by ENET $n$ _MMFR[DATA], written to or read from the PHY.

**Table 40-46. MDIO Clause 45 Transactions**

Transaction Type	Description
Address	A write transaction to the internal address register of the device/port. The data section of the frame contains the value to be stored in the device's internal address "pointer" register for further transactions.
Write	Data write to a register. The 16 bit data will be written to the register identified by the device-internal address.
Read	Data is read from the register identified by the device-internal address.
Read inc.	Read with address postincrement. The register identified by the device-internal address is read. After this, the device-internal address is incremented. If the address register is all '1' (0xFFFF) no increment is done (i.e. increment does not wrap around).

### 40.7.17.3 MDIO clock generation

The MDC clock is generated from the internal bus clock (i.e., IPS bus clock) divided by the value programmed in ENET $n$ \_MSCR[MII\_SPEED].

### 40.7.17.4 MDIO operation

To perform an MDIO access, set the MDIO command register (ENET $n$ \_MMFR) according to the description provided in MII Management Frame Register (ENET $n$ \_MMFR).

To check when the programmed access completes, read the ENET $n$ \_EIR[MII] field.

Figure 40-18. MDIO access overview

## 40.7.18 Ethernet interfaces

The following Ethernet interfaces are implemented:

- Fast Ethernet MII (Media Independent Interface)
- RMII 10/100 using interface converters/gaskets

The following table shows how to configure ENET registers to select each interface.

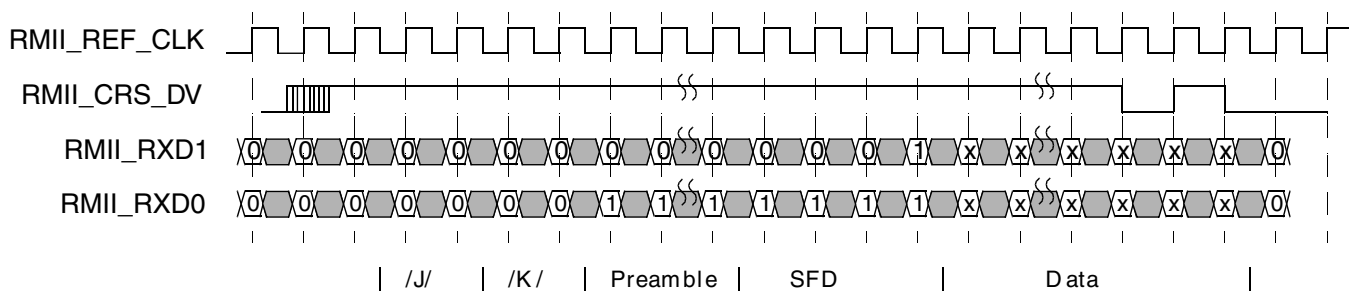

Mode	RCR[RMII_10T]	RCR[RMII_MODE]
MII - 10 Mbit/s	—	0
MII - 100 Mbit/s	—	0
RMII - 10 Mbit/s	1	1
RMII - 100 Mbit/s	0	1

### 40.7.18.1 RMII interface

In RMII receive mode, for normal reception following assertion of CRS\_DV, RXD[1:0] is 00 until the receiver determines that the receive event has a proper start-of-stream delimiter (SSD).

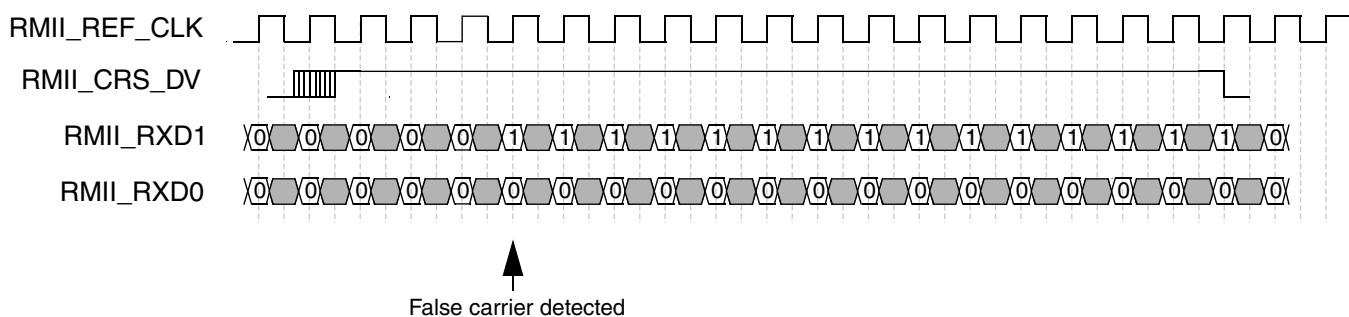

The preamble appears (RXD[1:0]=01) and the MACs begin capturing data following detection of SFD.

**Figure 40-19. RMII receive operation**

If a false carrier is detected (bad SSD), then RXD[1:0] is 10 until the end of the receive event. This is a unique pattern since a false carrier can only occur at the beginning of a packet where the preamble is decoded (RXD[1:0] = 01).

**Figure 40-20. RMII receive operation with false carrier**

In RMII transmit mode, TXD[1:0] provides valid data for each REF\_CLK period while TXEN is asserted.

**Figure 40-21. RMII transmit operation**

### 40.7.18.2 MII Interface — transmit

On transmit, all data transfers are synchronous to MII\_TXCLK rising edge. The MII data enable signal MII\_TXEN is asserted to indicate the start of a new frame, and remains asserted until the last byte of the frame is present on the MII\_TXD[3:0] bus.

Between frames, MII\_TXEN remains deasserted.

**Figure 40-22. MII transmit operation**

If a frame is received on the FIFO interface with an error (for example, RxBD[ME] set) the frame is subsequently transmitted with the MII\_TXER error signal for one clock cycle at any time during the packet transfer.

**Figure 40-23. MII transmit operation — errored frame**

### 40.7.18.2.1 Transmit with collision — half-duplex

When a collision is detected during a frame transmission (MII\_COL asserted), the MAC stops the current transmission, sends a 32-bit jam pattern, and re-transmits the current frame.

(See [Collision detection in half-duplex mode](#) for details)

Figure 40-24. MII transmit operation — transmission with collision

### 40.7.18.3 MII interface — receive

On receive, all signals are sampled on the MII\_RXCLK rising edge. The MII data enable signal, MII\_RXDV, is asserted by the PHY to indicate the start of a new frame and remains asserted until the last byte of the frame is present on MII\_RXD[3:0] bus.

Between frames, MII\_RXDV remains deasserted.

Figure 40-25. MII receive operation

## Functional description

If the PHY detects an error on the frame received from the line, the PHY asserts the MII error signal, MII\_RXER, for at least one clock cycle at any time during the packet transfer.

**Figure 40-26. MII receive operation — errored frame**

A frame received on the MII interface with a PHY error indication is subsequently transferred on the FIFO interface with RxBD[ME] set.

### 40.7.19 Interrupt coalescence

The purpose of the interrupt coalescing is to reduce the number of interrupts generated by the MAC so as to reduce the CPU loading.

To facilitate this interrupt coalescing, these registers are available with the same control and configuration fields.

- [Transmit Interrupt Coalescing Register \(ENET\\_TXIC\)](#)
- [Receive Interrupt Coalescing Register \(ENET\\_RXIC\)](#)

When coalescing is enabled by asserting the corresponding ICEN field and such interrupt is also enabled by the corresponding interrupt mask of the EIMR register, the MAC generates an interrupt when the threshold number of frames is reached (defined by ICFT) or when the threshold timer expires (defined by ICTT).

When coalescing is disabled by de-asserting ICEN, but interrupt is enabled by the corresponding interrupt mask of the EIMR register, the MAC generates an interrupt as they are received without using coalescing. Interrupt coalescing is done for each transmit and receive queue/class independently.

### 40.7.19.1 Interrupt coalescence setup

Interrupt coalescence supports both legacy and enhanced BDs. The following guidelines are recommended when setting up interrupt coalescence.

- When the MAC is configured for enhanced (IEEE 1588) mode, that is, enhanced BDs:
  - Set the INT bit in the enhanced received buffer descriptor to one.
  - Set the INT bit in the enhanced transmit buffer descriptor(s) to one.
- Clear the TXB and RXB fields in the EIMR register.

### 40.7.19.2 Updating the frame count threshold on-the-fly

To update the ICFT field in the RXIC and TXIC registers:

1. Disable interrupt coalescence by clearing the appropriate ICEN field. This will allow the internal interrupt coalescence counter to reset to zero.

#### NOTE

When disabling interrupt coalescence, if an interrupt event is pending, that is, the interrupt counter is not zero, then an interrupt will occur.

2. Write the new threshold value to the ICFT field.
3. Set ICEN to one.

#### NOTE

The ICFT field can be updated on-the-fly without disabling the ICEN field. The hardware interrupt will continue and there is a possibility that an interrupt will occur depending on the state of the hardware counter and the previous ICFT value.

### 40.7.19.3 Updating the timer threshold on-the-fly

To update the ICTT field in the RXIC and TXIC registers:

1. Disable interrupt coalescence by clearing the appropriate ICEN field. This will allow the internal interrupt coalescence counter to reset to zero.

#### NOTE

When disabling interrupt coalescence, if an interrupt event is pending, that is, the interrupt counter is not zero, then an interrupt will occur.

2. Write the new timer value to the ICTT field.
3. Set ICEN to one.

# Chapter 41

## Universal Serial Bus Controller (USB)

### 41.1 Chip-specific USB information

Table 41-1. Reference links to related information

### 41.2 Overview

The USB controller block provides high performance USB functionality that conforms to the *Universal Serial Bus Specification*, Rev. 2.0 (Compaq, Hewlett-Packard, Intel, Lucent, Microsoft, NEC, Philips; 2000), and the *On-The-Go and Embedded Host Supplement to the USB Revision 2.0 Specification* (Hewlett-Packard Company, Intel Corporation, LSI Corporation, Microsoft Corporation, Renesas Electronics Corporation, ST-Ericsson; 2012).

The USB controller consists of two independent USB controller cores: two On-The-Go (OTG) controller cores. Each controller core supports UTMI interface. See [Features](#) for more details. Both controller cores are single-port cores. For the OTG cores, there is only one port. The port can be used as either a downstream or an upstream port.

The following figure is a block diagram of USB.

Figure 41-1. USB block diagram

## 41.2.1 Features

There are two USB 2.0 controller cores in this chip:

- Controller Core 0 is also named 'OTG1 Core'; its connected port is named 'OTG1 port'.
- Controller Core 1 is also named 'OTG2 Core'; its connected port is named 'OTG2 port'.

The following list provides features of each of the controller cores.

- USB 2.0 Controller Core 0
  - High-Speed/Full-Speed/Low-Speed OTG core
  - HS/FS/LS UTMI compliant interface
  - High Speed, Full Speed and Low Speed operation in Host mode (with UTMI transceiver)
  - High Speed, and Full Speed operation in Peripheral mode (with UTMI transceiver)
  - Hardware support for OTG signaling, session request protocol, and host negotiation protocol
  - Up to 8 bidirectional endpoints
  - Support charger detection
- USB 2.0 Controller Core 1
  - High-Speed/Full-Speed/Low-Speed OTG core
  - HS/FS/LS UTMI compliant interface
  - High Speed, Full Speed and Low Speed operation in Host mode (with UTMI transceiver)
  - High Speed, and Full Speed operation in Peripheral mode (with UTMI transceiver)
  - Hardware support for OTG signaling, session request protocol, and host negotiation protocol
  - Up to 8 bidirectional endpoints
- Low-power mode with local and remote wake-up capability
- Serial PHY interfaces configurable for bidirectional/unidirectional and differential/single ended
- Embedded DMA controller in each core

## 41.2.2 Modes of Operation

The USB has two main modes of operation: normal mode and low power mode.

Each USB OTG controller core can operate in High Speed operation (480 Mbps), Full Speed operation (12 Mbps) and Low Speed operation (1.5 Mbps).

This chapter explains the operation modes.

### 41.2.2.1 Normal Mode

The OTG controller core can operate in Host mode and Device (Peripheral) mode. The Host-only controller core can operate in Host mode only.

Each USB controller core has its corresponding port, which can work in one or more interface modes.

#### NOTE

Each controller supports only the interface type listed below. Selecting a different interface type in the PORTSC.PTS field results in unpredictable behavior and may cause the system to hang.

- OTG1 port
  - This port supports on-chip UTMI transceiver only.
- OTG2 port
  - This port supports on-chip UTMI transceiver only.

### 41.2.2.2 Low-Power Mode

Each USB controller core has a low-power mode (Suspend mode) to save power consumption.

As described in the USB 2.0 specification, the device can go into the Suspend state after it sees a constant Idle state on the upstream facing port. The OTG controller core enters Suspend mode after 3 ms of inactivity on the port when it is in Device Operation mode. Host controllers, including the OTG controller in Host mode, do not suspend automatically but can be placed in Suspend mode by software.

Either the local Arm platform or the remote USB Host/Peripheral can initiate a wake-up sequence to resume USB communication. For details about Suspend/Resume, see [USB Power Control](#).

## 41.3 External Signals

The table found here describes the external signals of USB.

**Table 41-2. USB External Signals**

Signal	Description	Pad	Mode	Direction
USB_OTG1_PWR	To control PMIC to supply VBUS voltage	GPIO_AD_B0_02	ALT3	O
		GPIO_AD_B1_01	ALT0	
USB_OTG1_OC	External Input for VBUS over current detection	GPIO_AD_B0_03	ALT3	I
		GPIO_AD_B1_03	ALT0	
USB_OTG1_ID	OTG1 ID Signal	GPIO_AD_B0_01	ALT3	I
		GPIO_AD_B1_02	ALT0	
USB_OTG2_PWR	To control PMIC to supply VBUS voltage	GPIO_EMC_41	ALT3	O
		GPIO_AD_B0_15	ALT0	
USB_OTG2_OC	External Input for VBUS over current detection	GPIO_EMC_40	ALT3	I
		GPIO_AD_B0_14	ALT0	
USB_OTG2_ID	OTG2 ID Signal	GPIO_AD_B0_00	ALT3	I
		GPIO_AD_B1_00	ALT0	

## 41.4 Functional Description

These sections describe the functionality of the various building blocks of the USB.

### 41.4.1 USB 2.0 Controller Core 0/1

The USB 2.0 Controller 0/1 is an instantiation of an EHCI-compatible core which supports high-, full-, and low-speed operation.

In Host mode, this controller core supports high-, full-, and low-speed operation. In Device mode, it supports high- and full-speed operation.

#### 41.4.1.1 Host Mode

The controller supports direct connection of a HS/FS/LS device with on-chip UTMI transceiver.

Although there is no separate Transaction Translator block in the system, the transaction translator function normally associated with a USB 2.0 high speed hub has been implemented within the DMA and protocol engine blocks to support connection to full and low speed devices.

### 41.4.1.2 Peripheral (Device) Mode

- Up to eight bidirectional endpoints
- High/full-speed operation
- Support of HNP and SRP
- Remote wake-up capability

## 41.4.2 USB Power Control

The USB controller supports suspend and wake-up functionality.

The power control block allows for placing the transceiver in USB low power mode when USB bus is IDLE, and supports local and remote wake-up to bring the transceiver out of USB low power mode when needed. Additionally, the power control block can wake-up the Arm platform from core sleep mode by generating an interrupt.

### 41.4.2.1 Entering Low Power Suspend Mode

In Host operation mode, low power suspend mode is entered as follows:

1. Clear the ASE and PSE bits in USB\_USBCMD, and wait until the AS and PS bits in USB\_USBSTS become "0".
2. Set the "SUSPEND" bit in USB\_PORTSC1
3. Set the "PHCD" bit in USB\_PORTSC1
4. Set all PWD bits in USBPHY<sub>x</sub>\_PWD
5. Set CLKGATE in USBPHY<sub>x</sub>\_CTRL

#### NOTE

Step 3,4,5 shall be done in atomic operation. That is, interrupt should be disabled during these three steps.

For device operation mode, low power suspend mode is entered as follows:

1. After Host drive is IDLE for 3ms, an SLI interrupt is issued (the "DCSUSPEND" or "SLI" bit in USB\_USBSTS)
2. Set the "PHCD" bit on USB\_PORTSC1

3. Set all PWD bits in USBPHY<sub>x</sub>\_PWD
4. Set CLKGATE in USBPHY<sub>x</sub>\_CTRL

### NOTE

Step 2,3,4 shall be done in atomic operation. That is, interrupt should be disabled during these three steps.

## 41.4.2.2 Wake-Up Events

The power control block monitors the USB bus when the USB core is in the USB suspend state.

Depending on whether the core is on Host or Device mode, a number of wake-up conditions are monitored. Upon detection of a wake-up condition, an interrupt (asynchronous) will be generated to Arm platform if the related wake-up interrupt enable bit is set.

USB wake-up interrupt also re-activates the Arm platform clocks if they were stopped during the suspend.

### 41.4.2.2.1 Host Mode Events

The host controller wakes up on the following events:

- Remote Wake-up Request

A peripheral can request the host to reactivate the bus by driving wake-up signaling on the DM/DP lines. The power control block sends a wake-up request to the USB core when a J-K transition on DM/DP line is detected.

- Wake-Up On Overcurrent

If Wake-Up On Overcurrent is enabled (WKOC bit in the USB core register PORTSC1 is set '1'), the power control block sends a wake-up request to the USB core when an overcurrent event is detected.

- Wake-Up On Disconnect

If Wake-Up On Disconnect is enabled (WKDC bit in the USB core register PORTSC1 is set '1'), the power control block sends a wake-up request to the USB core when a disconnection event is detected (J-SE0/K-SE0 transition on DM/DP line).

- Wake-Up On Connect

If a Wake-Up On Connect is enabled (WKCN bit in the USB core register PORTSC1 is set '1'), the power control sub-block sends a wake-up request to the USB core when the connection event is detected (SE0-J/SE0-K transition on DM/DP line).

For a detailed description of register bits WKOC, WKDC, WKCN, please see [Port Status & Control \(USB\\_nPORTSC1\)](#).

### **41.4.3 Interrupts**

#### **41.4.3.1 USB Core Interrupts**

Each USB core uses one dedicated vector in the Interrupt Table. The vector numbers associated with each of the cores can be found in the Interrupt section.

With the exception of the wake-up interrupts, all of the interrupt sources are controlled in the USB Cores. Refer to the [Interrupt Enable Register \(USB\\_nUSBINTR\)](#) for details.

#### **41.4.3.2 USB Wake-Up Interrupts**

Each USB Core has an associated wake-up interrupt. The wake-up interrupts are generated outside of the USB controller cores, but using the same vector as the corresponding USB controller cores interrupt.

These interrupts are generated by the Power Control blocks which run on the 32 KHz standby clock. The wake-up interrupt is designed to work even when the USB and Arm platform clocks are disabled, such that a wake-up condition on the USB bus can re-activate the Arm platform clocks.

Because the wake-up interrupt is generated and cleared on a 32 KHz clock, this interrupt request responds very slowly to clear actions. For this reason, the software must disable the wake-up interrupt to clear the request flag. Disabling the interrupt masks the request instantaneously as this is clocked by the Arm platform clock. The software should wait for at least three 32 KHz clock cycles before re-enabling this interrupt to allow sufficient time for the request flag to clear. Because this interrupt is only used during low power modes of the USB, it is sufficient to enable the wake-up interrupt just prior to entering the USB suspend mode.

## 41.5 USB Operation Model

This section describes the detailed application knowledge for OTG1 and OTG2 ports.

### 41.5.1 Register Interface

Configuration, control and status registers are divided into three categories, identification, capability and operational registers.

#### NOTE

USB controller registers support only DWORD (32-bit) access.

- Identification registers are used to declare the slave interface presence along with the complete set of the hardware configuration parameters.
- Static, read only capability registers define the software limits, restrictions, and capabilities of the host/device controller.
- Operational registers are dynamic control or status registers that may be read only, read/write, or read/write-to-clear. The following sections define the use of these registers.

EHCI registers are listed alongside device registers to show the complementary nature of host and device control.

The following table describes the Interface register sets.

**Table 41-3. Interface Register Sets**

Offset	Register Set	Explanation
000h-07Ch	Identification Registers	Identification registers are used to declare the slave interface presence and include a table of the hardware configuration parameters.
100h-124h	Capability Registers	Capability registers specify the limits, restrictions, and capabilities of a host/device controller implementation. These values are used as parameters to the host/device controller driver.
080h-0FCh 140h-1FCh	Operational Registers	Operational registers are used by the system software to control and monitor the operational state of the host/device controller.

#### 41.5.1.1 Configuration, Control and Status Register Set

The following table describes the Device/Host capability registers.

#### NOTE

Depending on implementation, "x" can have the following values: UOG1 , UOG2.

**Table 41-4. Device/Host Capability Registers**

Offset	Size (Bytes)	Mnemonic	Register Name	Device Mode	Host Mode
000h	4	USB_X_ID	Identification Register	O	O
004h	4	USB_X_HWGENERAL	General Hardware Parameters	O	O

1B8h	4	USB_X_ENDPTSTATUS	Endpoint Status	O	X
1BCh	4	USB_X_ENDPTCOMPLE TE	Endpoint Complete	O	X
1C0	64	USB_X_ENDPTCTRL0	Endpoint Control Register 0-7	O	X
1C4		USB_X_ENDPTCTRL1			
...		....			
1DCh		USB_X_ENDPTCTRL7			

**NOTE**

"O" means the register is available in host/device operation mode;

"X" means the register is reserved in host/device operation mode

**41.5.1.2 Identification Registers**

Identification registers are used to declare the slave interface presence and include a table of the hardware configuration parameters.

**41.5.1.3 OTG Operations**

## 41.5.2 Host Data Structures

This section defines the interface data structures used to communicate control, status, and data between HCD (software) and the Enhanced Host Controller (hardware).

The data structure definitions in this chapter support a 32-bit memory buffer address space. The interface consists of a Periodic Schedule, Periodic Frame List, Asynchronous Schedule, Isochronous Transaction Descriptors, Split-transaction Isochronous Transfer Descriptors, Queue Heads, and Queue Element Transfer Descriptors.

The periodic frame list is the root of all periodic (isochronous and interrupt transfer type) transfers for the host controller. The asynchronous list is the root for all the bulk and control transfers. Isochronous data streams are managed using Isochronous Transaction Descriptors. Isochronous split-transaction data streams are managed with Split-transaction Isochronous Transfer Descriptors. All Interrupt, Control, and Bulk data streams are managed via queue heads and Queue Element Transfer Descriptors. These data structures are optimized to reduce the total memory footprint of the schedule and to reduce (on average) the number of memory accesses needed to execute a USB transaction.

Note that software must ensure that no interface data structure reachable by the EHCI host controller spans a 4 K-page boundary.

The data structures defined in this section are (from the host controller's perspective) a mix of read-only and read/writeable fields. The host controller must preserve the read-only fields on all data structure writes.

### 41.5.2.1 Periodic Frame List

This schedule is for all periodic transfers (isochronous and interrupt). The periodic schedule is referenced from the operational registers space using the `USB_PERIODICLISTBASE` address register and the `USB_FRINDEX` register.

The periodic schedule is based on an array of pointers called the Periodic Frame List.

The `USB_PERIODICLISTBASE` address register is combined with the `USB_FRINDEX` register to produce a memory pointer into the frame list. The Periodic Frame List implements a sliding window of work over time.

The following figure shows the organization of periodic schedule.

**Figure 41-2. Periodic Schedule Organization**

Split transaction Interrupt, Bulk and Control are also managed using queue heads and queue element transfer descriptors.

The periodic frame list is a 4 K-page aligned array of Frame List Link pointers. The length of the frame list may be programmable. The programmability of the periodic frame list is exported to system software via the USB\_HCCPARAMS register. If non-programmable, the length is 1024 elements. If programmable, the length can be selected by system software as one of 256, 512, or 1024 elements. An implementation must support all three sizes. Programming the size (that is, the number of elements) is accomplished by system software writing the appropriate value into Frame List Size field in the USB\_USBCMD register.

Frame List Link pointers direct the host controller to the first work item in the frame's periodic schedule for the current micro-frame. The link pointers are aligned on DWord boundaries within the Frame List.

The table below illustrates the format of the Frame list element pointer.

**Table 41-5. Format of Frame List Element Pointer**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
----	----	----	----	----	----	----	----	----	----	----	----	----	----	----	----	----	----	----	----	----	----	---	---	---	---	---	---	---	---	---	---	--

*Table continues on the next page...*

**Table 41-5. Format of Frame List Element Pointer (continued)**

Frame List Link Pointer	0	Typ	03-00H
-------------------------	---	-----	--------

Frame List Link pointers always reference memory objects that are 32-byte aligned. The referenced object may be an isochronous transfer descriptor for high-speed devices, a split-transaction isochronous transfer descriptor (for full-speed isochronous endpoints), or a queue head (used to support high-, full- and low-speed interrupt). System software should not place non-periodic schedule items into the periodic schedule. The least significant bits in a frame list pointer are used to key the host controller as to the type of object the pointer is referencing.

The least significant bit is the T-Bit (bit 0). When this bit is set to a one, the host controller never uses the value of the frame list pointer as a physical memory pointer. The Typ field is used to indicate the exact type of data structure being referenced by this pointer. The value encodings are.

**Table 41-6. Typ Field Value Definitions**

Value	Meaning
00b	Isochronous Transfer Descriptor
01b	Queue Head
10b	Split Transaction Isochronous Transfer Descriptor.
11b	Frame Span Traversal Node.

### 41.5.2.2 Asynchronous List Queue Head Pointer

The Asynchronous Transfer List (based at the USB\_ASYNC\_LIST\_ADDR register) is where all of the control and bulk transfers are managed.

Host controllers use this list only when it reaches the end of the periodic list, the periodic list is disabled, or the periodic list is empty.

**Figure 41-3. Asynchronous Schedule Organization**

The Asynchronous list is a simple circular list of queue heads. The USB\_ASYNCLISTADDR register is simply a pointer to the next queue head. This implements a pure round-robin service for all queue heads linked into the asynchronous list.

### 41.5.2.3 Isochronous (High-Speed) Transfer Descriptor (iTd)

The format of an isochronous transfer descriptor is shown in the table below.

This structure is used only for high-speed isochronous endpoints. All other transfer types should use queue structures. Isochronous TDs must be aligned on a 32-byte boundary.

**Table 41-7. Isochronous Transaction Descriptor (iTd)**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Host Controller Read/Write

Host Controller Read Only

These fields may be modified by the host controller if the I/O field indicates an OUT.

### 41.5.2.3.1 Next Link Pointer

The first DWord of an iTD is a pointer to the next schedule data structure.

The following table describes the Next Schedule Element pointer field.

**Table 41-8. Next Schedule Element Pointer**

Bit	Description
31-5 Link Pointer (LP)	These bits correspond to memory address signals [31:5], respectively. This field points to another Isochronous Transaction Descriptor (iTID/siTID) or Queue Head (QH).
4-3	These bits are reserved and their value has no effect on operation. Software should initialize this field to zero.

*Table continues on the next page...*

**Table 41-8. Next Schedule Element Pointer (continued)**

Reserved	
2-1 QH/(s)iTD Select (Typ)	This field indicates to the Host Controller whether the item referenced is an iTD, siTD or a QH. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are:  Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor) 11b FSTN (frame span traversal node)
0 Terminate (T)	1= Link Pointer field is not valid. 0= Link Pointer field is valid.

### 41.5.2.3.2 iTD Transaction Status and Control List

DWords 1 through 8 are eight slots of transaction control and status.

Each transaction description includes:

- Status results field
- Transaction length (bytes to send for OUT transactions and bytes received for IN transactions).
- Buffer offset. The PG and Transaction X Offset fields are used with the buffer pointer list to construct the starting buffer address for the transaction.

The host controller uses the information in each transaction description plus the endpoint information contained in the first three DWords of the Buffer Page Pointer list, to execute a transaction on the USB.

The following table describes iTD Transaction Status and Control fields.

**Table 41-9. iTD Transaction Status and Control**

Bit	Description
31-28 Status	This field records the status of the transaction executed by the host controller for this slot. This field is a bit vector with the following encoding:
Bit	Definition
31	Active. Set to one by software to enable the execution of an isochronous transaction by the Host Controller. When the transaction associated with this descriptor is completed, the Host Controller sets this bit to zero indicating that a transaction for this element should not be executed when it is next encountered in the schedule.
30	Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). If an overrun condition occurs, no action is necessary.
29	Babble Detected. Set to one by the Host Controller during status update when "babble" is detected during the transaction generated by this descriptor.

*Table continues on the next page...*

**Table 41-9. iTD Transaction Status and Control (continued)**

Bit	Description
28	Transaction Error (XactErr). Set to one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). This bit may only be set for isochronous IN transactions.
27-16 Transaction X Length	For an OUT, this field is the number of data bytes the host controller sends during the transaction. The host controller is not required to update this field to reflect the actual number of bytes transferred during the transfer. For an IN, the initial value of the endpoint to deliver. During the status update, the host controller writes back the field is the number of bytes the host expects the number of bytes successfully received. The value in this register is the actual byte count (0±zero length data, 1±one byte, 2±two bytes, etc.). The maximum value this field may contain is 0xC00 (3072).
15 Interrupt On Complete (IOC)	If this bit is set to one, it specifies that when this transaction completes, the Host Controller should issue an interrupt at the next interrupt threshold.
14-12 Page Select (PG)	These bits are set by software to indicate which of the buffer page pointers the offset field in this slot should be concatenated to produce the starting memory address for this transaction. The valid range of values for this field is 0 to 6.
11-0 Transaction X Offset	This field is a value that is an offset, expressed in bytes, from the beginning of a buffer. This field is concatenated onto the buffer page pointer indicated in the adjacent PG field to produce the starting buffer address for this transaction.

### 41.5.2.3.3 iTD Buffer Page Pointer List (Plus)

DWords 9-15 of an isochronous transaction descriptor are nominally page pointers (4 K aligned) to the data buffer for this transfer descriptor. This data structure requires the associated data buffer to be contiguous (relative to virtual memory), but allows the physical memory pages to be non-contiguous.

Seven page pointers are provided to support the expression of eight isochronous transfers. The seven pointers allow for 3 (transactions) \* 1024 (maximum packet size) \* 8 (transaction records) (24576 bytes) to be moved with this data structure, regardless of the alignment offset of the first page.

Because each pointer is a 4 K aligned page pointer, the least significant 12 bits in several of the page pointers are used for other purposes.

The tables below illustrate the field descriptions.

**Table 41-10. iTD Buffer Pointer Page 0 (Plus)**

Bit	Description
31-12 Buffer Pointer (Page 0)	This is a 4 K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11-8 Endpoint Number (Endpt)	This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.

*Table continues on the next page...*

**Table 41-10. iTD Buffer Pointer Page 0 (Plus) (continued)**

Bit	Description
7 Reserved	Bit reserved for future use and should be initialized by software to zero.
6-0 Device Address	This field selects the specific device serving as the data source or sink.

**Table 41-11. iTD Buffer Pointer Page 1 (Plus)**

Bit	Description
31-12 Buffer Pointer (Page 1)	This is a 4K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11 Direction (I/O)	0 = OUT; 1 = IN. This field encodes whether the high-speed transaction should use an IN or OUT PID.
10-0 Maximum Packet Size	This directly corresponds to the maximum packet size of the associated endpoint ( <i>wMaxPacketSize</i> ). This field is used for high-bandwidth endpoints where more than one transaction is issued per transaction description (per micro-frame). This field is used with the <i>Multi</i> field to support high-bandwidth pipes. This field is also used for all IN transfers to detect packet babble. Software should not set a value larger than 1024 (400h). Any value larger yields undefined results.

**Table 41-12. iTD Buffer Pointer Page 2 (Plus)**

Bit	Description
31-12 Buffer Pointer	This is a 4K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11-2 Reserved	This bit reserved for future use and should be set to zero.
1-0 Multi	This field is used to indicate to the host controller the number of transactions that should be executed per transaction description (per micro-frame). The valid values are:  Value Meaning 00b Reserved. A zero in this field yields undefined results. 01b One transaction to be issued for this endpoint per micro- frame. 10b Two transactions to be issued for this endpoint per micro- frame. 11b Three transactions to be issued for this endpoint per micro- frame.

**Table 41-13. iTD Buffer Pointer Page 3-6**

Bit	Description
31-12 Buffer Pointer	This is a 4 K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11-0 Reserved	These bits reserved for future use and should be set to zero.

### 41.5.2.4 Split Transaction Isochronous Transfer Descriptor (siTD)

All Full-speed isochronous transfers through the internal transaction translator are managed using the siTD data structure. This data structure satisfies the operational requirements for managing the split transaction protocol.

The following table shows the Split Transaction Isochronous Transfer Descriptor (siTD).

**Table 41-14. Split Transaction Isochronous Transfer Descriptor**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Addr

- 2. 0C-13: Transfer results

Host Controller Read/Write

Host Controller Read Only

#### 41.5.2.4.1 Next Link Pointer

DWord0 of a siTD is a pointer to the next schedule data structure.

The following table describes the Next Link Pointer fields.

**Table 41-15. Next Link Pointer**

Bit	Description
31-5	Next Link Pointer (LP). This field contains the address of the next data object to be processed in the periodic list and corresponds to memory address signals [31:5], respectively.

*Table continues on the next page...*

**Table 41-15. Next Link Pointer (continued)**

Bit	Description
4-3	Reserved. These bits must be written as zeros.
2-1	QH/(s)iTD Select (Typ). This field indicates to the Host Controller whether the item referenced is an iTD/siTD or a QH. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are:  Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor) 11b FSTN (frame span traversal node)
0	Terminate (T).  1 = Link Pointer field is not valid. 0 = Link Pointer is valid.

#### 41.5.2.4.2 siTD Endpoint Capabilities/Characteristics

DWords 1 and 2 specify static information about the full-speed endpoint, the addressing of the parent Companion Controller, and micro-frame scheduling control.

The tables below describe the Endpoint and transaction translator characteristics and micro-frame schedule control fields.

**Table 41-16. Endpoint and Transaction Translator Characteristics**

Bit	Description
31	Direction (I/O). 0 = OUT; 1 = IN. This field encodes whether the full-speed transaction should be an IN or OUT.
30-24	Port Number. This field is the port number of the recipient Transaction Translator.
23	Reserved. Bit reserved and should be set to zero.
22-16	Hub Address. This field holds the device address of the Companion Controllers' hub.
15-12	Reserved. Field reserved and should be set to zero.
11-8	Endpoint Number (Endpt). This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.
7	Reserved. Bit is reserved for future use. It should be set to zero.
6-0	Device Address. This field selects the specific device serving as the data source or sink.

**Table 41-17. Micro-frame Schedule Control**

Bit	Description
31-16	Reserved. This field reserved for future use. It should be set to zero.
15-8	Split Completion Mask (mFrame C-Mask). This field (along with the <i>Active</i> and <i>SplitX-state</i> fields in the <i>Status</i> byte) is used to determine during which micro-frames the host controller should execute complete-split transactions. When the criteria for using this field is met, an all zeros value has undefined behavior. The host

*Table continues on the next page...*

**Table 41-17. Micro-frame Schedule Control (continued)**

Bit	Description
	controller uses the value of the three low-order bits of the FRINDEX register to index into this bit field. If the FRINDEX register value indexes to a position where the <i>mFrame C-Mask</i> field is a one, then this siTD is a candidate for transaction execution. There may be more than one bit in this mask set.
7-0	Split Start Mask ( <i>mFrame S-mask</i> ). This field (along with the <i>Active</i> and <i>SplitX-state</i> fields in the <i>Status</i> byte) is used to determine during which micro-frames the host controller should execute start-split transactions. The host controller uses the value of the three low-order bits of the FRINDEX register to index into this bit field. If the FRINDEX register value indexes to a position where the <i>mFrame S-mask</i> field is a one, then this siTD is a candidate for transaction execution. An all zeros value in this field, in combination with existing periodic frame list has undefined results.

### 41.5.2.4.3 siTD Transfer State

DWords 3-6 are used to manage the state of the transfer.

The following table describes siTD transfer state fields.

**Table 41-18. siTD Transfer Status and Control**

Bit	Description
31	Interrupt On Complete ( <i>ioc</i> ). 0 = Do not interrupt when transaction is complete. 1 = Do interrupt when transaction is complete. When the host controller determines that the split transaction has completed it asserts a hardware interrupt at the next interrupt threshold.
30	Page Select ( <i>P</i> ). Used to indicate which data page pointer should be concatenated with the <i>CurrentOffset</i> field to construct a data buffer pointer (0 selects <i>Page 0</i> pointer and 1 selects <i>Page 1</i> ). The host controller is not required to write this field back when the siTD is retired ( <i>Active</i> bit transitioned from a one to a zero).
29-26	Reserved. This field reserved for future use and should be set to zero.
25-16	Total Bytes To Transfer. This field is initialized by software to the total number of bytes expected in this transfer. Maximum value is 1023 (3FFh)
15-8	$\mu$ Frame Complete-split Progress Mask ( <i>C-prog-Mask</i> ). This field is used by the host controller to record which split-completes has been executed.
<b>7-0: Status—This field records the status of the transaction executed by the host controller for this slot. It is a bit vector with the encoding shown in the following rows.</b>	
7	Active. Set to one by software to enable the execution of an isochronous split transaction by the Host Controller.
6	ERR. Set to a one by the Host Controller when an ERR response is received from the Companion Controller.
5	Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). In the case of an under run, the Host Controller transmits an incorrect CRC (thus invalidating the data at the endpoint). If an overrun condition occurs, no action is necessary.
4	Babble Detected. Set to a one by the Host Controller during status update when "babble" is detected during the transaction generated by this descriptor.
3	Transaction Error ( <i>XactErr</i> ). Set to a one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). This bit is set only for IN transactions.
2	Missed Micro-Frame. The host controller detected that a host-induced hold-off caused the host controller to miss a required complete-split transaction.

Table continues on the next page...

**Table 41-18. siTD Transfer Status and Control (continued)**

Bit	Description
1	<p>Split Transaction State (SplitXstate). The bit encodings are:</p> <p>Value Meaning</p> <p>00b Do Start Split.</p> <p>This value directs the host controller to issue a Start split transaction to the endpoint when a match is encountered in the S-mask.</p> <p>01b Do Complete Split.</p> <p>This value directs the host controller to issue a Complete split transaction to the endpoint when a match is encountered in the C-mask.</p>
0	Reserved. Bit reserved for future use and should be set to zero.

#### 41.5.2.4.4 siTD Buffer Pointer List (plus)

DWords 4 and 5 are the data buffer page pointers for the transfer. This structure supports one physical page cross. The most significant 20 bits of each DWord in this section are the 4 K (page) aligned buffer pointers.

The least significant 12 bits of each DWord are used as additional transfer state. The following table describes the siTD buffer pointer fields.

**Table 41-19. Buffer Page Pointer List (plus)**

Bit	Description
31-12	Buffer Pointer List. Bits [31:12] of DWords 4 and 5 are 4 K page aligned physical memory addresses. These bits correspond to physical address bits [31:12] respectively. The lower 12 bits in each pointer are defined and used as specified below. The field <i>P</i> (see <a href="#">siTD Transfer State</a> ) specifies the <i>current</i> active pointer.
Bits 11-0 (Page 0)	Current Offset—The 12 least significant bits of the Page 0 pointer are the current byte offset for the current page pointer (as selected with the page indicator bit ( <i>P</i> field)). The host controller is not required to write this field back when the siTD is retired ( <i>Active</i> bit transitioned from a one to a zero).
<b>Bits 11-0 (Page 1)—The least significant bits of the Page 1 pointer are split into three subfields as shown in the following rows.</b>	
11-5 (Page 1)	Reserved
4-3 (Page 1)	<p>Transaction position (TP). This field is used with T-count to determine whether to send <i>all</i>, <i>first</i>, <i>middle</i>, or <i>last</i> with each outbound transaction payload. System software must initialize this field with the appropriate starting value. The host controller must correctly manage this state during the lifetime of the transfer. The bit encodings are:</p> <p>Value Meaning</p> <p>00b All. The entire full-speed transaction data payload is in this transaction (that is, less than or equal to 188 bytes).</p> <p>01b Begin. This is the first data payload for a full-speed that is greater than 188 bytes.</p> <p>10B Mid. This is the <i>middle</i> payload for a full-speed OUT transaction that is larger than 188 bytes.</p>

*Table continues on the next page...*

**Table 41-19. Buffer Page Pointer List (plus) (continued)**

Bit	Description
	11b End. This is the <i>last</i> payload for a full-speed OUT transaction that was larger than 188 bytes.
2-0 (Page 1)	Transaction count (T-Count). Software initializes this field with the number of OUT start-splits this transfer requires. Any value larger than 6 is undefined.

#### 41.5.2.4.5 siTD Back Link Pointer

DWord 6 of a siTD is simply another schedule link pointer. This pointer is always zero, or references a siTD, and it cannot reference any other schedule data structure.

The following table describes the siTD back link pointer fields.

**Table 41-20. siTD Back Link Pointer**

Bit	Description
31-5	siTD Back Pointer. This field is a physical memory pointer to a siTD.
4-1	Reserved. This field is reserved for future use. It should be set to zero.
0	Terminate (T). 1 = siTD Back Pointer field is not valid. 0 = siTD Back Pointer field is valid.

#### 41.5.2.5 Queue element transfer descriptor (qTD)

This data structure is only used with a queue head. It describes one or more USB transactions to transfer up to 20480 (5\*4096) bytes.

The structure contains two structure pointers used for queue advancement, a DWord of transfer state, and a five-element array of data buffer pointers.

It is 32 bytes and must be physically contiguous.

The buffer associated with this transfer must be virtually contiguous. The buffer may start on any byte boundary; however, for optimal utilization of on-chip busses it is recommended to align the buffers on a 32-byte boundary. A separate buffer pointer list element must be used for each physical page in the buffer, regardless of whether the buffer is physically contiguous.

Host controller updates (host controller writes) to stand-alone qTDs only occur during transfer retirement. References in the following bit field definitions of updates to the qTD are to the qTD portion of a queue head.

The following table shows the queue element transfer descriptor data structure.

**Table 41-21. Queue element transfer descriptor data structure**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Addr

Buffer Pointer (page 3)														Reserved										1B-18								
Buffer Pointer (page 4)														Reserved										1F-1C								

1. 08-0F: Transfer Results

Host Controller Read/Write

Host Controller Read Only

Queue Element Transfer Descriptors must be aligned on 32-byte boundaries.

#### 41.5.2.5.1 Next qTD Pointer

The first DWord of an element transfer descriptor is a pointer to another transfer element descriptor.

The following table describes Next qTD pointer fields.

**Table 41-22. qTD Next Element Transfer Pointer (DWord 0)**

Bit	Description
31-5	Next Transfer Element Pointer. This field contains the physical memory address of the next qTD to be processed. The field corresponds to memory address signals[31:5], respectively.
4-1	Reserved

*Table continues on the next page...*

**Table 41-22. qTD Next Element Transfer Pointer (DWord 0) (continued)**

0	Terminate (T). 1= pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Host Controller that there are no more valid entries in the queue.
---	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

### 41.5.2.5.2 Alternate Next qTD Pointer

The second DWord of a queue element transfer descriptor is used to support hardware-only advance of the data stream to the next transfer descriptor on short packet. To be more explicit the host controller always uses this pointer when the current qTD is retired due to short packet.

The following table describes the TD Alternate Next Element Transfer Pointer field descriptions.

**Table 41-23. TD Alternate Next Element Transfer Pointer (DWord 1)**

Bit	Description
31-5	Alternate Next Transfer Element Pointer. This field contains the physical memory address of the next qTD to be processed in the event that the current qTD execution encounters a short packet (for an IN transaction). The field corresponds to memory address signals [31:5], respectively.
4-1	Reserved
0	Terminate (T). 1= pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Host Controller that there are no more valid entries in the queue.

### 41.5.2.5.3 qTD Token

The third DWord of a queue element transfer descriptor contains most of the information the host controller requires to execute a USB transaction (the remaining endpoint-addressing information is specified in the queue head).

**NOTE**

The field descriptions forward reference fields defined in the queue head. Where necessary, these forward references are preceded with a QH notation.

The following table describes the TD Token fields.

**Table 41-24. TD Token (DWord 2)**

Bit	Description
31 Data Toggle	This is the data toggle sequence bit. The use of this bit depends on the setting of the <i>Data Toggle Control</i> bit in the queue head.

*Table continues on the next page...*

Table 41-24. TD Token (DWord 2) (continued)

Bit	Description						
30-16 Total Bytes to Transfer	<p>This field specifies the total number of bytes to be moved with this transfer descriptor. This field is decremented by the number of bytes actually moved during the transaction, only on the successful completion of the transaction. The maximum value software may store in this field is 5 * 4K (5000H). This is the maximum number of bytes 5 page pointers can access. If the value of this field is zero when the host controller fetches this transfer descriptor (and the active bit is set), the host controller executes a zero-length transaction and retires the transfer descriptor. It is not a requirement for OUT transfers that <i>Total Bytes To Transfer</i> be an even multiple of QHD.Maximum Packet Length. If software builds such a transfer descriptor for an OUT transfer, the last transaction is always less than QHD.Maximum Packet Length.</p> <p>Although it is possible to create a transfer up to 20K this assumes the 1<sup>st</sup> offset into the first page is 0. When the offset cannot be predetermined, crossing past the 5th page can be guaranteed by limiting the total bytes to 16K**. Therefore, the maximum recommended transfer is 16 K(4000H).</p>						
15 Interrupt On Complete (IOC)	If this bit is set to a one, it specifies that when this qTD is completed, the Host Controller should issue an interrupt at the next interrupt threshold.						
14-12 Current Page (C_Page)	This field is used as an index into the qTD buffer pointer list. Valid values are in the range 0H to 4H. The host controller is not required to write this field back when the qTD is retired.						
11-10 Error Counter (CERR)	<p>This field is a 2-bit down counter that keeps track of the number of consecutive Errors detected while executing this qTD. If this field is programmed with a non-zero value during set-up, the Host Controller decrements the count and writes it back to the qTD if the transaction fails. If the counter counts from one to zero, the Host Controller marks the qTD inactive, sets the <i>Halted</i> bit to a one, and error status bit for the error that caused <i>CERR</i> to decrement to zero. An interrupt is generated if the <i>USB Error Interrupt Enable</i> bit in the USBINTR register is set to a one. If HCD programs this field to zero during set-up, the Host Controller does not count errors for this qTD and there is no limit on the retries of this qTD. Note that write-backs of intermediate execution state are to the queue head overlay area, not the qTD.</p> <p>Transaction Error - Decrement Data Buffer Error - No Decrement<sup>3</sup> Stalled - No Decrement<sup>1</sup> Babble Detected - No Decrement<sup>1</sup> No Error - No Decrement<sup>2</sup></p> <table border="1"> <thead> <tr> <th>Error</th> <th>Decrement Counter</th> </tr> </thead> <tbody> <tr> <td>1</td> <td>Detection of Babble or Stall automatically halts the queue head. Thus, count is not decremented</td> </tr> <tr> <td>2</td> <td> <p>If the EPS field indicates a HS device or the queue head is in the Asynchronous Schedule (and <i>PIDCode</i> indicates an IN or OUT) and a bus transaction completes and the host controller does not detect a transaction error, then the host controller should reset <i>CERR</i> to extend the total number of errors for this transaction. For example, <i>CERR</i> should be reset with maximum value (3) on each successful completion of a transaction. The host controller must never reset this field if the value at the start of the transaction is 00b.</p> <p>See <a href="#">Split Transaction Interrupt</a> for CERR adjustment rules when the EPS field indicates a FS or LS device and the queue head is in the Periodic Schedule. See <a href="#">Asynchronous - Do Complete Split</a> for CERR adjustment rules when the EPS field indicates a FS or LS device, the queue head is in the Asynchronous schedule and the <i>PIDCode</i> indicates a SETUP.</p> </td> </tr> </tbody> </table>	Error	Decrement Counter	1	Detection of Babble or Stall automatically halts the queue head. Thus, count is not decremented	2	<p>If the EPS field indicates a HS device or the queue head is in the Asynchronous Schedule (and <i>PIDCode</i> indicates an IN or OUT) and a bus transaction completes and the host controller does not detect a transaction error, then the host controller should reset <i>CERR</i> to extend the total number of errors for this transaction. For example, <i>CERR</i> should be reset with maximum value (3) on each successful completion of a transaction. The host controller must never reset this field if the value at the start of the transaction is 00b.</p> <p>See <a href="#">Split Transaction Interrupt</a> for CERR adjustment rules when the EPS field indicates a FS or LS device and the queue head is in the Periodic Schedule. See <a href="#">Asynchronous - Do Complete Split</a> for CERR adjustment rules when the EPS field indicates a FS or LS device, the queue head is in the Asynchronous schedule and the <i>PIDCode</i> indicates a SETUP.</p>
Error	Decrement Counter						
1	Detection of Babble or Stall automatically halts the queue head. Thus, count is not decremented						
2	<p>If the EPS field indicates a HS device or the queue head is in the Asynchronous Schedule (and <i>PIDCode</i> indicates an IN or OUT) and a bus transaction completes and the host controller does not detect a transaction error, then the host controller should reset <i>CERR</i> to extend the total number of errors for this transaction. For example, <i>CERR</i> should be reset with maximum value (3) on each successful completion of a transaction. The host controller must never reset this field if the value at the start of the transaction is 00b.</p> <p>See <a href="#">Split Transaction Interrupt</a> for CERR adjustment rules when the EPS field indicates a FS or LS device and the queue head is in the Periodic Schedule. See <a href="#">Asynchronous - Do Complete Split</a> for CERR adjustment rules when the EPS field indicates a FS or LS device, the queue head is in the Asynchronous schedule and the <i>PIDCode</i> indicates a SETUP.</p>						

Table continues on the next page...

**Table 41-24. TD Token (DWord 2) (continued)**

Bit	Description	
	3	Data buffer errors are host problems. They don't count against the device's retries.
	<b>NOTE:</b> Software must not program CERR to a value of zero when the EPS field is programmed with a value indicating a Full- or Low-speed device. This combination could result in undefined behavior.	
9-8 PID Code	This field is an encoding of the token, which should be used for transactions associated with this transfer descriptor. Encodings are:	
	00b	OUT Token generates token (E1H)
	01b	IN Token generates token (69H)
	10b	SETUP Token generates token (2DH) (undefined if endpoint is an interrupt, the queue head is non-zero) transfer type, for example, $\mu$ Frame S-mask field in.
	11b	Reserved
7-0 Status	This field is used by the Host Controller to communicate individual command execution states back to HCD. This field contains the status of the last transaction performed on this qTD. The bit encodings are:	
	Bit	Status Field Description
	7	Active. Set to one by software to enable the execution of transactions by the Host Controller.
	6	Halted. Set to one by the Host Controller during status updates to indicate that a serious error has occurred at the device/endpoint addressed by this qTD. This can be caused by babble, the error counter counting down to zero, or reception of the STALL handshake from the device during a transaction. Any time that a transaction results in the Halted bit being set to a one, the Active bit is also set to zero.
	5	Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overflow) or is unable to supply data fast enough during transmission (under run). If an overflow condition occurs, the Host Controller forces a timeout condition on the USB, invalidating the transaction at the source. If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.
	4	Babble Detected. Set to a one by the Host Controller during status update when "babble" is detected during the transaction. In addition to setting this bit, the Host Controller also sets the <i>Halted</i> bit to a one. Because "babble" is considered a fatal error for the transfer, setting the Halted bit to a one insures that no more transactions occur because of this descriptor.
	3	Transaction Error (XactErr). Set to a one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.
	2	Missed Micro-Frame. This bit is ignored unless the <i>QH.EPS</i> field indicates a full- or low-speed endpoint and the queue head is in the periodic list. This bit is set when the host controller detected that a host-induced hold-off caused the host controller to miss a required complete-split transaction. If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.
1	Split Transaction State (SplitXstate). This bit is ignored by the host controller unless the <i>QH.EPS</i> field indicates a full- or low-speed endpoint. When a Full- or Low-speed device, the host controller uses this bit to track the state of the split-	

*Table continues on the next page...*

**Table 41-24. TD Token (DWord 2) (continued)**

Bit	Description
	<p>transaction. The functional requirements of the host controller for managing this state bit and the split transaction protocol depends on whether the endpoint is in the periodic or asynchronous schedule. The bit encodings are:</p> <p>Value Meaning</p> <p>0b Do Start Split. This value directs the host controller to issue a Start split transaction to the endpoint.</p> <p>1b Do Complete Split. This value directs the host controller to issue a Complete split transaction to the endpoint.</p>
0	<p>Ping State (P)/ERR. If the <i>QH.EPS</i> field indicates a High-speed device and the <i>PID_Code</i> indicates an OUT endpoint, then this is the state bit for the Ping protocol. The bit encodings are:</p> <p>Value Meaning</p> <p>0b Do OUT. This value directs the host controller to issue an OUT PID to the endpoint.</p> <p>1b Do Ping. This value directs the host controller to issue a PING PID to the endpoint.</p> <p>If the <i>QH.EPS</i> field does not indicate a High-speed device, then this field is used as an error indicator bit. It is set to a one by the host controller whenever a periodic split-transaction receives an ERR handshake.</p>

#### 41.5.2.5.4 qTD Buffer Page Pointer List

The last five DWords of a queue element transfer descriptor is an array of physical memory address pointers. These pointers reference the individual pages of a data buffer.

System software initializes Current Offset field to the starting offset into the current page, where current page is selected through the value in the *C\_Page* field.

The following table describes the qTD Buffer Pointer(s) (DWords 3-7) fields.

**Table 41-25. qTD Buffer Pointer(s) (DWords 3-7)**

Bit	Description
31-12	<p>Buffer Pointer List. Each element in the list is a 4 K page aligned physical memory address. The lower 12 bits in each pointer are reserved (except for the first one), as each memory pointer must reference the start of a 4 K page. The field <i>C_Page</i> specifies the current active pointer. When the transfer element descriptor is fetched, the starting buffer address is selected using <i>C_Page</i> (similar to an array index to select an array element). If a transaction spans a 4K buffer boundary, the host controller must detect the page-span boundary in the data stream, increment <i>C_Page</i> and advance to the next buffer pointer in the list, and conclude the transaction through the new buffer pointer.</p>
11-0	<p>Current Offset (Reserved). This field is reserved in all pointers except the first one (for example Page 0). The host controller should ignore all reserved bits. For the page 0 current offset interpretation, this field is the byte offset into the current page (as selected by <i>C_Page</i>). The host controller is not required to write this field back when the qTD is retired. Software should ensure the Reserved fields are initialized to zero.</p>

### 41.5.2.6 Queue Head

The table located in this section shows the Queue Head structure layout.

The following table shows the queue head structure layout.

**Table 41-26. Queue Head Structure Layout**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Addr

Buffer Pointer (Page 4)														Reserved														2F-2C <sup>3</sup>					

1. 04-0B: Static endpoint state.
2. These fields are used exclusively to support split transactions to USB 2.0 hubs
3. 10-2F: Transfer overlay.
4. 14-27: Transfer results.

Host Controller Read/Write

Host Controller Read Only

### 41.5.2.6.1 Queue Head Horizontal Link Pointer

The first DWord of a Queue Head contains a link pointer to the next data object to be processed after any required processing in this queue has been completed, as well as the control bits defined below.

This pointer may reference a queue head or one of the isochronous transfer descriptors. It must not reference a queue element transfer descriptor.

The following table describes the Queue head DWord 0 fields.

**Table 41-27. Queue Head DWord 0**

Bit	Description
31-5	Queue Head Horizontal Link Pointer (QHLP). This field contains the address of the next data object to be processed in the horizontal list and corresponds to memory address signals [31:5], respectively.
4-3	Reserved
2-1	QH/(s)iTD Select (Typ). This field indicates to the hardware whether the item referenced by the link pointer is an iTD, siTD or a QH. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are:  Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor) 11b FSTN (frame span traversal node)
0	Terminate (T). 1=Last QH (pointer is invalid). 0=Pointer is valid. If the queue head is in the context of the periodic list, a one bit in this field indicates to the host controller that this is the end of the periodic list. This bit is ignored by the host controller when the queue head is in the Asynchronous schedule. Software must ensure that queue heads reachable by the host controller always have valid horizontal link pointers.

### 41.5.2.6.2 Queue Head Endpoint Capabilities/Characteristics

The second and third DWords of a Queue Head specifies static information about the endpoint. This information does not change over the lifetime of the endpoint.

There are three types of information in this region:

- **Endpoint Characteristics.** These are the USB endpoint characteristics including addressing, maximum packet size, and endpoint speed.
- **Endpoint Capabilities.** These are adjustable parameters of the endpoint. They effect how the endpoint data stream is managed by the host controller.
- **Split Transaction Characteristics.** This data structure is used to manage full- and low-speed data streams for bulk, control, and interrupt via split transactions to USB2.0 Hub Transaction Translator. There are additional fields used for addressing the hub and scheduling the protocol transactions (for periodic).

The host controller must not modify the bits in this region.

The following table describes the Endpoint characteristics: Queue head DWord 1 fields.

**Table 41-28. Endpoint Characteristics: Queue Head DWord 1**

Bit	Description	
31-28	Nak Count Reload (RL). This field contains a value, which is used by the host controller to reload the Nak Counter field.	
27	Control Endpoint Flag (C). If the <i>QH.EPS</i> field indicates the endpoint is not a high-speed device, and the endpoint is a control endpoint, then software must set this bit to a one. Otherwise, it should always set this bit to zero.	
26-16	Maximum Packet Length. This directly corresponds to the maximum packet size of the associated endpoint ( <i>wMaxPacketSize</i> ). The maximum value this field may contain is 0x400 (1024).	
15	Head of Reclamation List Flag (H). This bit is set by System Software to mark a queue head as being the head of the reclamation list.	
14	Data Toggle Control (DTC). This bit specifies where the host controller should get the initial data toggle on an overlay transition.  0b Ignore DT bit from incoming qTD. Host controller preserves DT bit in the queue head.  1b Initial data toggle comes from incoming qTD DT bit. Host controller replaces DT bit in the queue head from the DT bit in the qTD.	
13-12	Endpoint Speed (EPS). This is the speed of the associated endpoint. Bit combinations are:	
	Value	Meaning
	00b	Full-Speed (12 Mbits/sec)
	01b	Low-Speed (1.5 Mbits/sec)
	10b	High-Speed (480 Mbits/sec)
	11b	Reserved
This field must not be modified by the host controller.		
11-8	Endpoint Number (Endpt). This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.	
7	Inactivate on Next Transaction (I). This bit is used by system software to request that the host controller set the Active bit to zero. See <a href="#">Rebalancing the periodic schedule</a> , for full operational details. This field is only valid when the queue head is in the Periodic Schedule and the <i>EPS</i> field indicates a Full or Low-speed endpoint. Setting this bit to one when the queue head is in the Asynchronous Schedule or the <i>EPS</i> field indicates a high-speed device yields undefined results.	
6-0	Device Address. This field selects the specific device serving as the data source or sink.	

The table below describes the Endpoint capabilities: Queue head DWord 2 field descriptions.

**Table 41-29. Endpoint Capabilities: Queue Head DWord 2**

Bit	Description
31-30	High-Bandwidth Pipe Multiplier (Mult). This field is a multiplier used to key the host controller as the number of successive packets the host controller may submit to the endpoint in the current execution. The host controller makes the simplifying assumption that software properly initializes this field (regardless of location of queue head in the schedules or other run time parameters). The valid values are:  Value Meaning

*Table continues on the next page...*

**Table 41-29. Endpoint Capabilities: Queue Head DWord 2 (continued)**

	<p>00b Reserved. A zero in this field yields undefined results.</p> <p>01b One transaction to be issued for this endpoint per micro-frame.</p> <p>10b Two transactions to be issued for this endpoint per micro-frame.</p> <p>11b Three transactions to be issued for this endpoint per micro-frame.</p>
29-23	Port Number. This field is ignored by the host controller unless the <i>EPS</i> field indicates a full- or low-speed device. The value is the port number identifier on the USB 2.0 Hub (for hub at device address <i>Hub Addr</i> below), below which the full- or low-speed device associated with this endpoint is attached. This information is used in the split-transaction protocol.
22-16	Hub Addr. This field is ignored by the host controller unless the <i>EPS</i> field indicates a full- or low-speed device. The value is the USB device address of the USB 2.0 Hub below which the full- or low-speed device associated with this endpoint is attached. This field is used in the split-transaction protocol.
15-8	Split Completion Mask ( $\mu$ Frame C-Mask). This field is ignored by the host controller unless the <i>EPS</i> field indicates this device is a low- or full-speed device and this queue head is in the periodic list. This field (along with the <i>Active</i> and <i>SplitX-state</i> fields) is used to determine during which micro-frames the host controller should execute a complete-split transaction. When the criteria for using this field are met, a zero value in this field has undefined behavior. This field is used by the host controller to match against the three low-order bits of the FRINDEX register. If the FRINDEX register bits decode to a position where the $\mu$ Frame C- Mask field is a one, then this queue head is a candidate for transaction execution. There may be more than one bit in this mask set.
7-0	Interrupt Schedule Mask ( $\mu$ Frame S-mask). This field is used for all endpoint speeds. Software should set this field to a zero when the queue head is on the asynchronous schedule. A non-zero value in this field indicates an interrupt endpoint. The host controller uses the value of the three low-order bits of the FRINDEX register as an index into a bit position in this bit vector. If the $\mu$ Frame S-mask field has a one at the indexed bit position then this queue head is a candidate for transaction execution. If the <i>EPS</i> field indicates the endpoint is a high-speed endpoint, then the transaction executed is determined by the <i>PID_Code</i> field contained in the execution area. This field is also used to support split transaction types: Interrupt (IN/OUT). This condition is true when this field is non-zero and the <i>EPS</i> field indicates this is either a full- or low-speed device. A zero value in this field, in combination with existing in the periodic frame list has undefined results.

### 41.5.2.6.3 Transfer Overlay-Queue Head

The nine DWords in this area represent a transaction working space for the host controller. The general operational model is that the host controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, then it follows the Queue Head Horizontal Link Pointer to the next queue head. The host controller will never follow the Next Transfer Queue Element or Alternate Queue Element pointers unless it is actively attempting to advance the queue. For the duration of the transfer, the host controller keeps the incremental status of the transfer in the overlay area. When the transfer is complete, the results are written back to the original queue element.

The DWord3 of a Queue Head contains a pointer to the source qTD currently associated with the overlay. The host controller uses this pointer to write back the overlay area into the source qTD after the transfer is complete.

The following table describes the current qTD link pointer field descriptions.

**Table 41-30. Current qTD Link Pointer**

Bit	Description
31-5	Current Element Transaction Descriptor Link Pointer. This field contains the address Of the current transaction being processed in this queue and corresponds to memory address signals [31:5], respectively.
4-0	Reserved (R). These bits are ignored by the host controller when using the value as an address to write data. The actual value may vary depending on the usage.

The DWords 4-11 of a queue head are the transaction overlay area. This area has the same base structure as a Queue Element Transfer Descriptor. The queue head utilizes the reserved fields of the page pointers to implement tracking the state of split transactions.

This area is characterized as an overlay because when the queue is advanced to the next queue element, the source queue element is merged onto this area. This area serves as execution cache for the transfer.

The table below describes the Host-controller rules for bits in overlay.

**Table 41-31. Host-Controller Rules for Bits in Overlay (DWords 5, 6, 8 and 9)**

DWord	Bit	Description
5	4-1	Nak Counter (NakCnt) $\mu$ RW. This field is a counter the host controller decrements whenever a transaction for the endpoint associated with this queue head results in a Nak or Nyet response. This counter is reloaded from <i>RL</i> before a transaction is executed during the first pass of the reclamation list (relative to an Asynchronous List Restart condition). It is also loaded from <i>RL</i> during an overlay.
6	31	Data Toggle. The <i>Data Toggle Control</i> controls whether the host controller preserves this bit when an overlay operation is performed.
6	15	Interrupt On Complete (IOC). The IOC control bit is always inherited from the source qTD when the overlay operation is performed.
6	11-10	Error Counter (C_ERR). This two-bit field is copied from the qTD during the overlay and written back during queue advancement.
6	0	Ping State (P)/ERR. If the <i>EPS</i> field indicates a high-speed endpoint, then this field should be preserved during the overlay operation.
8	7-0	Split-transaction Complete-split Progress (C-prog-mask). This field is initialized to zero during any overlay. This field is used to track the progress of an interrupt split-transaction.
9	4-0	Split-transaction Frame Tag (Frame Tag). This field is initialized to zero during any overlay. This field is used to track the progress of an interrupt split-transaction.
9	11-5	S-bytes. Software must ensure that the <i>S-bytes</i> field in a <i>qTD</i> is zero before activating the <i>qTD</i> . This field is used to keep track of the number of bytes sent or received during an IN or OUT split transaction.

### 41.5.2.7 Periodic Frame Span Traversal Node (FSTN)

This data structure is to be used only for managing Full- and Low-speed transactions that span a Host-frame boundary.

See [Host Controller Operational Model for FSTNs](#) for full operational details. Software must not use an FSTN in the Asynchronous Schedule. An FSTN in the Asynchronous schedule results in undefined behavior. Software must not use the FSTN feature with a host controller whose USB\_HCIVERSION register indicates a revision implementation below 0096h. FSTNs are not defined for implementations before 0.96 and their use yields undefined results.

**Table 41-32. Frame Span Traversal Node Structure Layout**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Addr

1. Must be set to indicate a queue head

Host Controller Read/Write

Host Controller Read Only

#### 41.5.2.7.1 FSTN Normal Path Pointer

The first DWord of an FSTN contains a link pointer to the next schedule object. This object can be of any valid periodic schedule data type.

The following table describes the FSTN normal path pointer fields.

**Table 41-33. FSTN Normal Path Pointer Field Descriptions**

Bit	Description
31-5	Normal Path Link Pointer (NPLP). This field contains the address of the next data object to be processed in the periodic list and corresponds to memory address signals [31:5], respectively.
4-3	Reserved
2-1	QH/(s)iTD/FSTN Select (Typ). This field indicates to the Host Controller whether the item referenced is a iTD/siTD, a QH or an FSTN. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are:  Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor) 11b FSTN (Frame Span Traversal Node)
0	Terminate (T).  1 = Link Pointer field is not valid. 0 = Link Pointer is valid.

### 41.5.2.7.2 FSTN Back Path Link Pointer

The second DWord of an FSTN node contains a link pointer to a queue head.

If the T-bit in this pointer is zero, then this FSTN is a Save-Place indicator. Its Typ field must be set by software to indicate the target data structure is a queue head. If the T-bit in this pointer is set to one, then this FSTN is the Restore indicator. When the T-bit is one, the host controller ignores the Typ field.

The following table describes the FSTN back path link pointer fields.

**Table 41-34. FSTN Back Path Link Pointer Field Descriptions**

Bit	Description
31-5	Back Path Link Pointer (BPLP). This field contains the address of a Queue Head. This field corresponds to memory address signals [31:5], respectively.
4-3	Reserved
2-1	Typ. Software must ensure this field is set to indicate the target data structure is a Queue Head. Any other value in this field yields undefined results.
0	Terminate (T). 1=Link Pointer field is not valid (that is the host controller must not use bits [31:5] as a valid memory address). This value also indicates that this FSTN is a Restore indicator.  0=Link Pointer is valid (that is the host controller may use bits [31:5] (in combination with the CTRLDSSEGMENT register if applicable) as a valid memory address). This value also indicates that this FSTN is a Save-Place indicator.

## 41.5.3 Host Operational Model

The general operational model is for the enhanced interface host controller hardware and enhanced interface host controller driver (generally referred to as system software).

Each significant operational feature of the EHCI host controller is discussed in a separate section. Each section presents the operational model requirements for the host controller hardware. Where appropriate, recommended system software operational models for features are also presented.

### 41.5.3.1 Host Controller Initialization

After initial power-on or HCRreset (hardware or through HCRreset bit in the USB\_USBCMD register), all of the operational registers are at their default values. After a hardware reset, only the operational registers not contained in the Auxiliary power well are at their default values.

The following table describes the default values of operational registers.

**Table 41-35. Default Values of Operational Register Space**

Operational Register	Default Value (after Reset)
USB_USBCMD	00080000h (00080B00h, if <i>Asynchronous Schedule Park Capability is one</i> )
USB_USBSTS	00001000h
USB_USBINTR	00000000h
USB_FRINDEX	00000000h
USB_CTRLDSSEGMENT	00000000h
USB_PERIODICLISTBASE	Undefined
USB_ASYNC_LISTADDR	Undefined
USB_CONFIGFLAG	00000000h
USB_PORTSC1	00002000h (w/PPC set to one); 00003000h (w/PPC set to zero)

To initialize the host controller, software should perform the following steps:

- Write the appropriate value to the USB\_USBINTR register to enable the appropriate interrupts.
- Write the base address of the Periodic Frame List to the USB\_PERIODICLIST BASE register. If no work items are in the periodic schedule, all elements of the Periodic Frame List should have their T-Bits set to one.
- Write the USB\_USBCMD register to set the desired interrupt threshold, frame list size (if applicable) and turn the host controller ON through setting the Run/Stop bit.

At this point, the host controller is up and running and the port registers begin reporting device connects, and so on. System software can enumerate a port through the reset process (where the port is in the enabled state). At this point, the port is active with SOFs occurring down the enabled ports, but the schedules have not enabled. To communicate with devices through the asynchronous schedule, system software must write the USB\_ASYNC\_LISTADDR register with the address of a control or bulk queue head. Software must then enable the asynchronous schedule by writing one to the Asynchronous Schedule Enable bit in the USB\_USBCMD register. To communicate with devices through the periodic schedule, system software must enable the periodic schedule by writing one to the Periodic Schedule Enable bit in the USB\_USBCMD register.

#### **NOTE**

The schedules can be turned on before the first port is reset (and enabled).

When the USB\_USBCMD register is written, system software must ensure the appropriate bits are preserved, depending on the intended operation.

### 41.5.3.2 Port Routing and Control

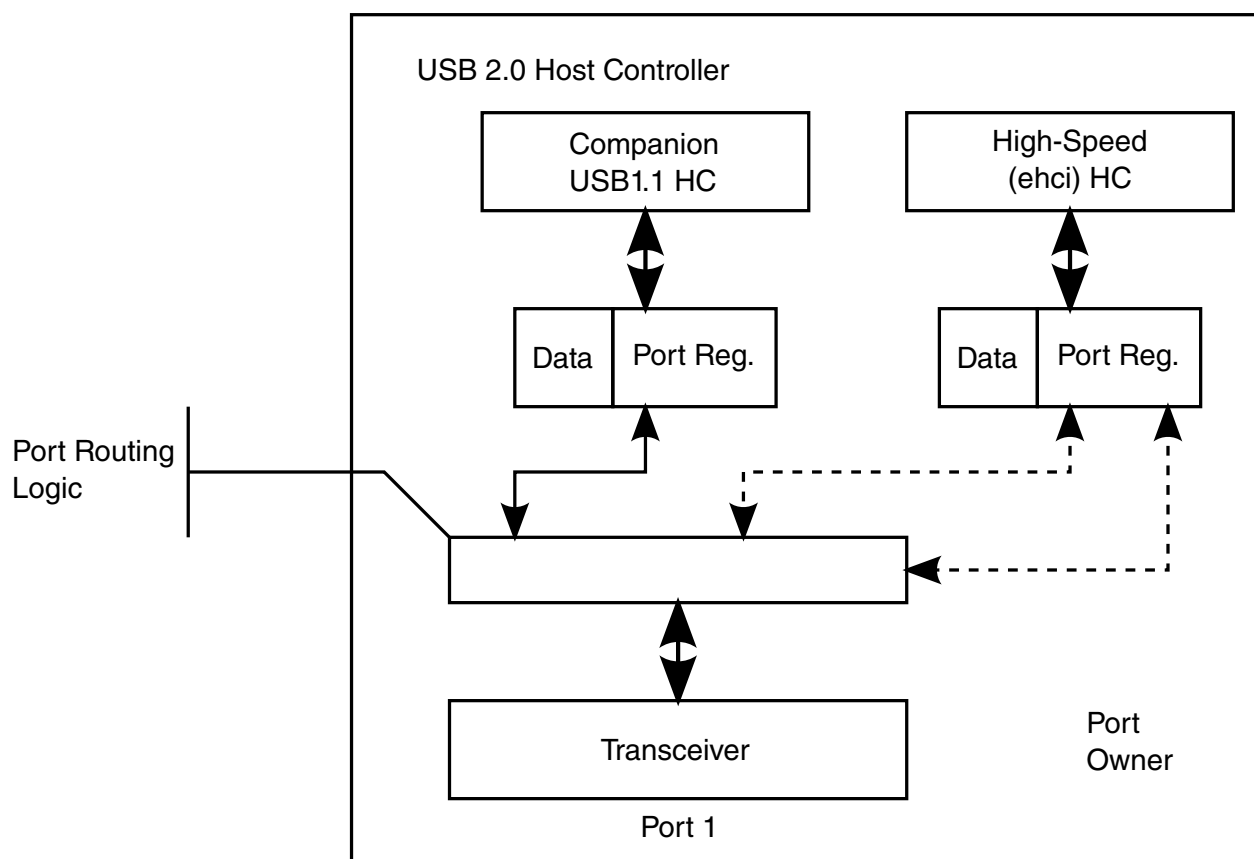

The EHCI specification defines that a USB 2.0 Host controller is comprised of one high-speed host controller, which implements the EHCI programming interface and 0 to N USB 1.1 companion host controllers.

Companion host controllers (cHCs) may be implementations of either Universal or Open host controller specifications. This configuration is used to deliver the required full USB 2.0-defined port capability; for example, Low-, Full-, and High-speed capability for every port.

#### NOTE

The USB controllers do not require nor support companion controllers to support Full and Low Speed devices. Full and Low Speed devices are supported within the USB controller by emulating the functionality of a high-speed HUB. Therefore, no port routing is present in the controller. Please refer to [Embedded Transaction Translator Function](#) for details.

The following figure illustrates a simple block diagram of the port routing logic and its relationship to the high-speed and companion host controllers within a USB 2.0 host controller.

**Figure 41-4. Example USB 2.0 Host Controller Port Routing Block Diagram**

There exists one transceiver per physical port and each host controller block has its own port status and control registers. The EHCI controller has port status and control registers for every port. Each companion host controller has only the port control and status registers it is required to operate. Either the EHCI host controller or one companion host controller controls each transceiver. Routing logic lies between the transceiver, the port status and control registers.<sup>1</sup>

The port routing logic is controlled from signals originating in the EHCI host controller. The EHCI host controller has a global routing policy control field and per-port ownership control fields. The Configured Flag (CF) bit is the global routing policy control. At power-on or reset, the default routing policy is to the companion controllers (if they exist). If the system does not include a driver for the EHCI host controller and the host controller includes Companion Controllers, then the ports still work in Full- and Low-speed mode (assuming the system includes a driver for the companion controllers). In general, when the EHCI owns the ports, the companion host controllers' port registers do not see a connect indication from the transceiver. Similarly, when a companion host controller owns a port, the EHCI controller's port registers do not see a connect indication

1. The routing logic should not be implemented in the 480 MHz clock domain of the transceiver.

from the transceiver. The details on the rules for the port routing logic are described in the following sections. The USB 2.0 host controller must be implemented as a multi-function PCI device if the implementation includes companion controllers. The companion host controllers' function numbers must be less than the EHCI host controller function number. The EHCI host controller must be a larger function number with respect to the companion host controllers associated with this EHCI host controller. If a PCI device implementation contains only an EHCI controller (that is no companion controllers or other PCI functions), then the EHCI host controller must be function zero, in accordance with the PCI Specification. The N\_CC field in the Structural Parameter register (HCSPARAMS) indicates whether the controller implementation includes companion host controllers. When N\_CC has a non-zero value there exists companion host controllers. If N\_CC has a value of zero, then the host controller implementation does not include companion host controllers. If the host controller root ports are exposed to attachment of full- or low-speed devices, the ports always fails the high-speed chirp during reset and the ports are not enabled. System software can notify the user of the illegal condition. This type of implementation requires a USB 2.0 hub be connected to a root port to provide full and low-speed device connectivity.

System software uses information in the host controller capability registers to determine how the ports are routed to the companion host controllers. See [Host Controller Structural Parameters \(USB\\_nHCSPARAMS\)](#)

#### 41.5.3.2.1 Port Routing Control through EHCI Configured (CF) Bit

Each port in the USB 2.0 host controller are routed either to a single companion host controller or to the EHCI host controller.

The port routing logic is controlled by two mechanisms in the EHCI HC: a host controller global flag and per-port control. The Configured Flag (CF) bit, is used to globally set the policy of the routing logic. Each port register has a Port Owner control bit which allows the EHCI Driver to explicitly control the routing of individual ports. Whenever the CF bit transitions from zero to one (this transition is only available under program control) the port routing unconditionally routes all of the port registers to the EHCI HC (all Port Owner bits go to zero). While the CF-bit is one, the EHCI Driver controls individual ports' routing through the Port Owner control bit. Likewise, whenever the CF bit transitions from one to zero (as a result of Aux power application, HCRESET, or software writing zero to CF-bit), the port routing unconditionally routes all of the port registers to the appropriate companion HC. The default value for the EHCI HC's CF bit (after Aux power application or HCRESET) is zero.

The *view* of the port depends on the current owner. A Universal or Open companion host controller will see port register bits consistent with the appropriate specification. Port bit definitions that are required for EHCI host controllers are not visible to companion host controllers.

The following table summarizes the default routing for all the ports, based on the value of the EHCI HC's CF bit.

**Table 41-36. Default Port Routing Depending on EHCI HC CF Bit**

HS CF Bit	Default Port Ownership	Explanation
0B	Companion HCs	The companion host controllers own the ports and only Full- and Low-speed devices are supported in the system. The exact port assignments are implementation dependent. The ports behave only as Full- and Low-speed ports in this configuration
1B	EHCI HC	The EHCI host controller has default ownership over all of the ports. The routing logic inhibits device connect events from reaching the companion HCs' port status and control registers when the port owner is the EHCI HC. The EHCI HC has access to the additional port status and control bits defined in this specification (see <a href="#">Port Status &amp; Control (USB_nPORTSC1)</a> ). The EHCI HC can temporarily release control of the port to a companion HC by setting the <i>PortOwner</i> bit in the PORTSC1 register to one.

#### 41.5.3.2.2 Port Routing Control through PortOwner and Disconnect Event

Manipulating the port routing through the CF-bit is an extreme process and not intended to be used during normal operation.

The normal mode of port ownership transferal is on the granularity of individual ports using the Port Owner bit in the EHCI HC's USB\_PORTSC1 register (for hand-offs from EHCI to companion host controllers). Individual port ownership is returned to the EHCI controller when the port registers a device disconnect. When the disconnect is detected, the port routing logic immediately returns the port ownership to the EHCI controller. The companion host controller port register detects the device disconnect and operates normally.

Under normal operating conditions (assuming all HC drivers loaded and operational and the EHCI *CF-bit* is set to one), the typical port enumeration sequence proceeds as illustrated below:

- Initial condition is that EHCI is port owner. A device is connected causing the port to detect a connect, set the port connect change bit and issue a port-change interrupt (if enabled).
- EHCI Driver identifies the port with the new connect change bit asserted and sends a change report to the hub driver. Hub driver issues a GetPortStatus() request and

identifies the connect change. It then issues a request to clear the connect change, followed by a request to reset and enable the port.

- When the EHCI Driver receives the request to reset and enable the port, it first checks the value reported by the LineStatus bits in the USB\_PORTSC1 register. If they indicate the attached device is a full-speed device (for example, D+ is asserted), then the EHCI Driver sets the PortReset control bit to one (and sets the PortEnable bit to zero) which begins the reset-process. Software times the duration of the reset, then terminates reset signaling by writing zero to the port reset bit. The reset process is actually complete when software reads zero in the PortReset bit. The EHCI Driver checks the PortOwner bit in the USB\_PORTSC1 register. If set to one, the connected device is a high-speed device and EHCI Driver (root hub emulator) issues a change report to the hub driver and the hub driver continues to enumerate the attached device.
- At the time the EHCI Driver receives the port reset and enable request the LineStatus bits might indicate a low-speed device. Additionally, when the port reset process is complete, the PortEnable field may indicate that a full-speed device is attached. In either case the EHCI driver sets the PortOwner bit in the USB\_PORTSC1 register to one to release port ownership to a companion host controller.
- When the EHCI Driver sets PortOwner bit to one, the port routing logic makes the connection state of the transceiver available to the companion host controller port register and removes the connection state from the EHCI HC port. The EHCI USB\_PORTSC1 register observes and reports a disconnect event through the disconnect change bit. The EHCI Driver detects the connection status change (either by polling or by port change interrupt) and then sends a change report to the hub driver. When the hub driver requests that port-state, the EHCI Driver responds with a reset complete change set to one, a connect change set to one and a connect status set to zero. This information is derived directly from the EHCI port register. This allows the hub driver to assume the device was disconnected during reset. It acknowledges the change bits and wait for the next change event. While the EHCI controller does not own the port, it simply remains in a state where the port reports no device connected. The device-connect evaluation circuitry of the companion HC activates and detects the device, the companion Driver detects the connection and enumerates the port.

When a port is routed to a companion HC, it remains under the control of the companion HC until the device is disconnected from the root port (ignoring for now the scenario where EHCI's CF-bit transitions from 1b to 0b). When a disconnect occurs, the disconnect event is detected by both the companion HC port control and the EHCI port ownership control. On the event, the port ownership is returned immediately to the EHCI controller. The companion HC stack detects the disconnect and acknowledges as it would in an ordinary standalone implementation. Subsequent connects is detected by the EHCI port register and the process repeats.

### 41.5.3.2.3 Example Port Routing State Machine

The following figure illustrates an example of how the port ownership should be managed. The following sections describe the entry conditions to each state.

Figure 41-5. Port Owner Handoff State Machine

#### 41.5.3.2.3.1 EHCI HC Owner

Entry to this state occurs when one of the following events occur:

- When the EHCI HC's Configure Flag (CF) bit in the USB\_CONFIGFLAG register transitions from zero to one. This signals the fact that the system has a host controller driver for the EHCI HC and that all ports in the USB 2.0 host controller must default route to the EHCI controller.
- When the port is owned by a companion HC and the device is disconnected from the port. The EHCI port routing control logic is notified of the disconnect, and returns port routing to the EHCI controller. The connection state of the companion HC goes immediately to the disconnected state (with appropriate side effect to connect change, enable and enable change). The companion HC driver acknowledges the disconnect by setting the connect status change bit to zero. This allows the companion HC's driver to interact with the port completely through the disconnect process.
- When system software writes zero to the PortOwner bit in the USB\_PORTSC1 register. This allows software to take ownership of a port from a companion host controller. When this occurs, the routing logic to the companion HC effectively signals a disconnect to the companion HC's port status and control register.

### 41.5.3.2.3.2 Companion HC Owner

Entry to this state occurs whenever one of the following events occur:

- When the PortOwner field transitions from zero to one.
- When the HS-mode HC's Configure Flag (CF) is equal to zero.

On entry to this state, the routing logic allows the companion HC port register to detect a device connect. Normal port enumeration proceeds.

### 41.5.3.2.4 Port Power

The Port Power Control (PPC) bit in the USB\_HCSPARAMS register indicates whether the USB 2.0 host controller has port power control (see [Host Controller Structural Parameters \(USB\\_nHCSPARAMS\)](#)).

When this bit is zero, then the host controller does not support software control of port power switches. When in this configuration, the port power is always available and the companion host controllers must implement functionality consistent with port power always on. When the *PPC* bit is one, then the host controller implementation includes port power switches. Each available switch has an output enable, which is referred to in this discussion as PortPowerOutputEnable (PPE). PPE is controlled based on the state of the combination bits PPC bit, EHCI Configured (CF)-bit and individual Port Power (PP) bits.

The following table describes the summary behavioral model.

**Table 41-37. Port Power Enable Control Rules**

CF	CHC <sup>1</sup> (PP)	EHC <sup>2</sup> (PP)	Owner	PPE <sup>3</sup>	Description
0	0	X	CHC	0	When the EHCI controller is not configured, the port is owned by the companion host controller. When the companion HC's port power select is off, then the port power is off.
0	1	X	CHC	1	Similar to previous entry. When the companion HC's port power select is on, then the port power is on.
1	0	0	CHC	0	Port owner has port power turned off, the power to port is off.
1	0	0	EHC	0	Port owner has port power turned off, the power to port is off.
1	0	1	EHC	1	Port owner has port power on, so power to port is on.
1	0	1	CHC	1	If either HC has port power turned on, the power to the port is on.

*Table continues on the next page...*

**Table 41-37. Port Power Enable Control Rules (continued)**

1	1	0	EHC	1	If either HC has port power turned on, the power to the port is on.
1	1	0	CHC	1	Port owner has port power on, so power to port is on.
1	1	1	CHC	1	Port owner has port power on, so power to port is on.
1	1	1	EHC	1	Port owner has port power on, so power to port is on.

1. CHC (Companion Host Controller).
2. EHC (EHCI Host Controller).
3. PPE (Port Power Enable). This bit actually turns on the port power switch (if one exists).

### 41.5.3.2.5 Port Reporting Over-Current

Host controllers are by definition power providers on USB. Whether the ports are considered high- or low-powered is a platform implementation issue. Each EHCI USB\_PORTSC1 register has an over-current status and over-current change bit.

The functionality of these bits are specified in the USB Specification Revision 2.0.

The over current detection and limiting logic usually resides outside the host controller logic. This logic may be associated with one or more ports. When this logic detects an over-current condition it is made available to both the companion and EHCI ports. The effect of an over-current status on a companion host controller port is beyond the scope of this document.

The over-current condition effects the following bits in the USB\_PORTSC1 register on the EHCI port:

- Over-current Active bits are set to one. When the over-current condition goes away, the Over-current Active bit transitions from one to zero.
- Over-current Change bits are set to one. On every transition of the Over-current Active bit the host controller sets the Over-current Change bit to one. Software sets the Over-current Change bit to zero by writing one to this bit.
- Port Enabled/Disabled bit is set to zero. When this change bit gets set to one, then the Port Change Detect bit in the USB\_USBSTS register is set to one.
- Port Power (PP) bits may optionally be set to zero. There is no requirement in USB that a power provider shut off power in an over current condition. It is sufficient to limit the current and leave power applied. When the Over-current Change bit transitions from zero to one, the host controller also sets the Port Change Detect bit in the USB\_USBSTS register to one. In addition, if the Port Change Interrupt Enable bit in the USB\_USBINTR register is one, then the host controller issues an interrupt to the system. Refer to [Table 41-38](#) for summary behavior for over-current detection

when the host controller is halted (suspended from a device component point of view).

### 41.5.3.3 Suspend/Resume-Host Operational Model

The EHCI host controller provides an equivalent suspend and resume model as that defined for individual ports in a USB 2.0 Hub.

Control mechanisms are provided to allow system software to suspend and resume individual ports. The mechanisms allow the individual ports to be resumed completely through software initiation. Other control mechanisms are provided to parameterize the host controller's response (or sensitivity) to external resume events. In this discussion, host-initiated, or software initiated resumes are called Resume Events/Actions. Bus-initiated resume events are called wake-up events. The classes of wake-up events are:

- Remote-wake-up enabled device asserts resume signaling. In similar kind to USB 2.0 Hubs, EHCI controllers must always respond to explicit device resume signaling and wake-up the system (if necessary).
- Port connect and disconnect and over-current events. Sensitivity to these events can be turned on or off by using the per-port control bits in the USB\_PORTSC1 registers.

Selective suspend is a feature supported by every USB\_PORTSC1 register. It is used to place specific ports into a suspend mode. This feature is used as a functional component for implementing the appropriate power management policy implemented in a particular operating system. When system software intends to suspend the entire bus, it should selectively suspend all enabled ports, then shut off the host controller by setting the Run/Stop bit in the USB\_USBCMD register to zero. The EHCI sub-block can then be placed into a lower device state through the PCI power management interface (see Appendix A, Enhanced Host Controller Interface Specification for Universal Serial Bus, Revision 0.95, November 2000, Intel Corporation. <http://www.intel.com>).

When a wake event occurs, the system resumes operation and system software eventually set the Run/Stop bit to one and resume the suspended ports. Software must not set the Run/Stop bit to one until it is confirmed that the clock to the host controller is stable. This is usually confirmed in a system implementation in that all of the clocks in the system are stable before the Arm platform is restarted. So, by definition, if software is running, clocks in the system are stable and the Run/Stop bit in the USB\_USBCMD register can be set to one. Minimum system software delays are also defined in the PCI Power Management Specification. Refer to PCI Power Management Specification for more information.

### 41.5.3.3.1 Port Suspend/Resume

System software places individual ports into suspend mode by writing one into the appropriate USB\_PORTSC1 Suspend bit. Software must only set the Suspend bit when the port is in the enabled state (Port Enabled bit is one) and the EHCI is the port owner (PortOwner bit is zero).

The host controller may evaluate the Suspend bit immediately or wait until a micro-frame or frame boundary occurs. If evaluated immediately, the port is not suspended until the current transaction (if one is executing) completes. Therefore, there may be several micro-frames of activity on the port until the host controller evaluates the Suspend bit. The host controller must evaluate the Suspend bit at least every frame boundary.

System software can initiate a resume on a selectively suspended port by writing one to the Force Port Resume bit. Software should not attempt to resume a port unless the port reports that it is in the suspended state (see [Port Status & Control \(USB\\_nPORTSC1\)](#)). If system software sets Force Port Resume bit to one when the port is not in the suspended state, the resulting behavior is undefined. In order to assure proper USB device operation, software must wait for at least 10 ms after a port indicates that it is suspended (Suspend bit is one) before initiating a port resume through the Force Port Resume bit. When Force Port Resume bit is one, the host controller sends resume signaling down the port. System software times the duration of the resume (nominally 20 ms) then sets the Force Port Resume bit to zero. When the host controller receives the write to transition Force Port Resume to zero, it completes the resume sequence as defined in the USB specification, and sets both the Force Port Resume and Suspend bits to zero. Software-initiated port resumes do not affect the Port Change Detect bit in the USB\_USBSTS register nor do they cause an interrupt if the Port Change Interrupt Enable bit in the USB\_USBINTR register is one. An external USB event may also initiate a resume. The wake events are defined above. When a wake event occurs on a suspended port, the resume signaling is detected by the port and the resume is reflected downstream within 100  $\mu$ sec. The port's Force Port Resume bit is set to one and the Port Change Detect bit in the USB\_USBSTS register is set to one. If the Port Change Interrupt Enable bit in the USB\_USBINTR register is one the host controller issues a hardware interrupt.

System software observes the resume event on the port, delays a port resume time (nominally 20 ms), then terminates the resume sequence by writing zero to the Force Port Resume bit in the port. The host controller receives the write of zero to Force Port Resume, terminates the resume sequence and sets Force Port Resume and Suspend port bits to zero. Software can determine that the port is enabled (not suspended) by sampling the USB\_PORTSC1 register and observing that the Suspend and Force Port Resume bits are zero. Software must ensure that the host controller is running (that is HCHalted bit in the USB\_USBSTS register is zero), before terminating a resume by writing zero to a

port's Force Port Resume bit. If HCHalted is one when Force Port Resume is set to zero, then SOFs do not occur down the enabled port and the device returns to suspend mode in a maximum of 10 msec.

The table below summarizes the wake-up events. Whenever a resume event is detected, the Port Change Detect bit in the USB\_USBSTS register is set to one. If the Port Change Interrupt Enable bit is one in the USB\_USBINTR register, the host controller generates an interrupt on the resume event. Software acknowledges the resume event interrupt by clearing the Port Change Detect status bit in the USB\_USBSTS register.

**Table 41-38. Behavior During Wake-up Events**

Port Status and Signaling Type	Signaled Port Response	Device State	
		D0	Not D0
Port disabled, resume K-State received	No Effect	N/A	N/A
Port suspended, resume K-State received	Resume reflected downstream on signaled port. Force Port Resume status bit in USB_PORTSC1 register is set to one. Port Change Detect bit in USB_USBSTS register set to one.	[1], [2]	[2]
Port is enabled, disabled or suspended, and the port's WKDSCNNT_E bit is one. A disconnect is detected.	Depending in the initial port state, the USB_PORTSC1 Connected Enable status bits are set to zero, and the Connect Change status bit is set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [2]	[2]
Port is enabled, disabled or suspended, and the port's WKDSCNNT_E bit is zero. A disconnect is detected.	Depending on the initial port state, the USB_PORTSC1 Connect and Enable status bits are set to zero, and the Connect Change status bit is set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [3]	[3]
Port is not connected and the port's WKCNTNT_E bit is one. A connect is detected.	USB_PORTSC1 Connect Status and Connect Status Change bits are set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [2]	[2]
Port is not connected and the port's WKCNTNT_E bit is zero. A connect is detected.	USB_PORTSC1 Connect Status and Connect Status Change bits are set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [3]	[3]
Port is connected and the port's WKOC_E bit is one. An over-current condition occurs.	USB_PORTSC1 Over-current Active, Over-current Change bits are set to one. If Port Enable/Disable bit is one, it is set to zero. Port Change Detect bit in the USB_USBSTS register is set to one	[1], [2]	[2]
Port is connected and the port's WKOC_E bit is zero. An over-current condition occurs.	USB_PORTSC1 Over-current Active, Over-current Change bits are set to one. If Port Enable/Disable bit is one, it is set to zero. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [3]	[3]

[1] Hardware interrupt issued if Port Change Interrupt Enable bit in the USB\_USBINTR register is one.

[2] PME# asserted if enabled (Note: PME Status must always be set to one).

[3] PME# not asserted.

### 41.5.3.4 Schedule Traversal Rules

The host controller executes transactions for devices using a simple, shared-memory schedule.

The schedule is comprised of a few data structures, organized into two distinct lists. The data structures are designed to provide the maximum flexibility required by USB, minimize memory traffic and hardware / software complexity.

System software maintains two schedules for the host controller: a periodic schedule and an asynchronous schedule. The root of the periodic schedule is the USB\_PERIODICLISTBASE register (see [Frame List Base Address \(USB\\_nPERIODICLISTBASE\)](#))/ [Device Address \(USB\\_nDEVICEADDR\)](#)). The USB\_PERIODICLISTBASE register is the physical memory base address of the periodic frame list. The periodic frame list is an array of physical memory pointers. The objects referenced from the frame list must be valid schedule data structures as defined in [Host Data Structures](#). In each micro-frame, if the periodic schedule is enabled (see [Periodic scheduling threshold](#)) then the host controller must execute from the periodic schedule before executing from the asynchronous schedule. It only executes from the asynchronous schedule after it encounters the end of the periodic schedule. The host controller traverses the periodic schedule by constructing an array offset reference from the USB\_PERIODICLISTBASE and the USB\_FRINDEX registers (see the following figure). It fetches the element and begins traversing the graph of linked schedule data structures.

The end of the periodic schedule is identified by a next link pointer of a schedule data structure having its T-bit set to one. When the host controller encounters a T-Bit set to one during a horizontal traversal of the periodic list, it interprets this as an End-Of-Periodic-List mark. This causes the host controller to cease working on the periodic schedule and transitions immediately to traversing the asynchronous schedule. After the transition, the host controller executes from the asynchronous schedule until the end of the micro-frame.

The following figure illustrates the derivation of pointer into frame list array.

**Figure 41-6. Derivation of Pointer into Frame List Array**

When the host controller determines that it is the time to execute from the asynchronous list, it uses the operational register `USB_ASYNC_LIST_ADDR` to access the asynchronous schedule, see the figure below.

**Figure 41-7. General Format of Asynchronous Schedule List**

The `USB_ASYNC_LIST_ADDR` register contains a physical memory pointer to the next queue head. When the host controller makes a transition to executing the asynchronous schedule, it begins by reading the queue head referenced by the `USB_ASYNC_LIST_ADDR` register. Software must set queue head horizontal pointer T-bits to zero for queue heads in the asynchronous schedule. See [Asynchronous Schedule](#) for complete operational details.

#### 41.5.3.4.1 Example - Preserving Micro-Frame Integrity

One of the requirements of a USB host controller is to maintain Frame Integrity. This means that the HC must preserve the micro-frame boundaries.

For example, SOF packets must be generated on time (within the specified allowable jitter), and High-speed EOF1,2 thresholds must be enforced. The end of micro-frame timing points EOF1 and EOF2 are clearly defined in the USB Specification Revision 2.0. One implication of this responsibility is that the HC must ensure that it does not start transactions that do not complete before the end of the micro-frame. More precisely, no transactions should be started by the host controller, which do not complete in their entirety before the EOF1 point. In order to enforce this rule, the host controller must check each transaction before it starts to ensure that it completes before the end of the micro-frame.

So, what exactly needs to be involved in this check? Fundamentally, the transaction data payload, plus bit stuffing, plus transaction overhead must be taken into consideration. It is possible to be extremely accurate on how much time the next transaction takes. Take OUTs for an example. The host controller must fetch all of the OUT data from memory in order to send it onto the USB bus. A host controller implementation could pre-fetch all of the OUT data, and pre-compute the actual number of bits in the token and data packets. In addition, the system knows the depth of the target endpoint, so it could closely estimate turnaround time for handshake. In addition, the host controller knows the size of a handshake packet. Pre-computing effects of bit stuffing and summing up the other overhead numbers can allow the host controller to know exactly whether there is enough bus time, before EOF1 to complete the OUT transaction. To accomplish this particular approach takes an inordinate amount of time and hardware complexity.

The alternative is to make a reasonable guess whether the next transaction can be started. An example approximation algorithm is described below. This example algorithm relies on the EHCI policy that periodic transactions are scheduled first in the micro-frame. It is a reasonable assumption that software never over-commits the micro-frame to periodic transactions greater than the specification allowable 80%. In the available remaining 20% bandwidth, the host controller has some ability (in this example) to decide whether or not to execute a transaction. The result of this algorithm is that sometimes, under some circumstances a transaction is not executed that could have been executed. However, under all circumstances, a transaction is never started unless there is enough time in the frame to complete the transaction.

##### 41.5.3.4.1.1 Transaction Fit - A Best-Fit Approximation Algorithm

A curve is calculated which represents the latest start time for every packet size, at which software schedules the start of a periodic transaction.

This curve is the 80% bandwidth curve. Another curve is calculated which is the absolute, latest permitted start time for every packet size. This curve represents the absolute latest time, that a transaction of each packet size can be started and completed, in the micro-frame. A plot of these two curves are illustrated in Figure 41-8. The plot Y-axis represents the number of byte-times left in a frame.

The space between the 80% and the Last Start plots is bandwidth reclamation area. In this algorithm the host controller may skip transactions during this time if it is prudent.

The Best-Fit Approximation method plots a function ( $f(x)$ ) between the 80% and Last Start curves. The function  $f(x)$  adds a constant to every transaction's maximum packet size and the result compared with the number of bytes left in the frame. The constant represents an approximation of the effects of bit stuffing and protocol overhead. The host controller starts transactions whose results land above the function curve. The host controller will not start transactions whose results land below the function curve.

The following figure illustrates the Best-Fit Approximation.

**Figure 41-8. Best Fit Approximation**

The LastStart line was calculated in this example to assume the absolute worst-case bus overhead per transaction. The particular transaction used is a start-split, zero-length OUT transaction with a handshake. Summaries of the component parts are listed in the table below. The component times were derived from the protocol timings defined in the USB Specification Revision 2.0.

**Table 41-39. Example Worse-case Transaction Timing Components**

Component	Bit time	Byte Time	Explanation
-----------	----------	-----------	-------------

*Table continues on the next page...*

**Table 41-39. Example Worse-case Transaction Timing Components (continued)**

Split Token	76	9.5	Split token as defined in USB core specification. Includes sync, token, eop, and so on.
Host 2 Host IPG	88	11	Number of bit times required between consecutive host packets.
Token	67	8.375	Token as defined in USB core specification. Includes sync, token, eop, and so on.
Host 2 Host IPG	88	11	Token as defined in USB core specification. Includes sync, token, eop, and so on.
Data Packet (0 data bytes)	66.7	8.34	Zero-length data packet. Includes sync, PID, crc16, eop, and so on.
Turnaround time	721	90.125	Time for packet initiator (Host) to see the beginning of a response to a transmitted packet.
Handshake packet	48	6	Handshake packet as defined in USB core specification. Includes sync, PID, eop, and so on.
		144	Total

The exact details of the function ( $f(x)$ ) are up to the particular implementation. However, it should be obvious that the goal is to minimize the area under the curve between the approximation function and the Last Start curve, without dipping below the LastStart line, while at the same time keeping the check as simple as possible for hardware implementation. The  $f(x)$  in [Figure 41-8](#) was constructed using the following pseudo-code test on each transaction size data point. This algorithm assumes that the host controller keeps track of the remaining bits in the frame.

```

Algorithm CheckTransactionWillFit (MaximumPacketSize, HC_BytesLeftInFrame)
Begin
Local Temp = MaximumPacketSize + 192
Local rvalue = TRUE
If MaximumPacketSize >= 128 then
    Temp += 128
End If
If Temp > HC_BytesLeftInFrame then
    Rvalue = FALSE
End If
Return rvalue
End

```

This algorithm takes two inputs, the current maximum packet size of the transaction and the hardware counter of the number of bytes left in the current micro-frame. It unconditionally adds a simple constant of 192 to the maximum packet size to account for a first-order effect of transaction overhead and bit stuffing. If the transaction size is greater than or equal to 128 bytes, then an additional constant of 128 is added to the running sum to account for the additional worst-case bit stuffing of payloads larger than 128. An inflection point was inserted at 128 because the  $f(x)$  plot was getting close to the LastStart line.

### 41.5.3.5 Periodic Schedule Frame Boundaries vs Bus Frame Boundaries

The USB Specification Revision 2.0 requires that the frame boundaries (SOF frame number changes) of the high-speed bus and the full- and low-speed bus(s) below USB 2.0 Hubs be strictly aligned.

Super-imposed on this requirement is that USB 2.0 Hubs manage full- and low-speed transactions through a micro-frame pipeline (see start- (SS) and complete- (CS) splits illustrated in the following figure). A simple, direct projection of the frame boundary model into the host controller interface schedule architecture creates tension (complexity for both hardware and software) between the frame boundaries and the scheduling mechanisms required to service the full- and low-speed transaction translator periodic pipelines.

**Figure 41-9. Frame Boundary Relationship between HS bus and FS/LS Bus**

The simple projection, as the above figure illustrates, introduces frame-boundary wrap conditions for scheduling on both the beginning and end of a frame. In order to reduce the complexity for hardware and software, the host controller is required to implement one micro-frame phase shift for its view of frame boundaries. The phase shift eliminates the beginning of frame and frame-wrap scheduling boundary conditions.

The implementation of this phase shift requires that the host controller use one register value for accessing the periodic frame list and another value for the frame number value included in the SOF token. These two values are separate, but tightly coupled. The periodic frame list is accessed through the Frame List Index Register (USB\_FRINDEX) documented in [USB Frame Index \(USB\\_nFRINDEX\)](#) and initially illustrated in [Schedule Traversal Rules](#). Bits FRINDEX[2:0], represent the micro-frame number. The SOF value is coupled to the value of FRINDEX[13:3]. Both FRINDEX[13:3] and the SOF value are increment based on FRINDEX[2:0]. It is required that the SOF value be delayed from the FRINDEX value by one micro-frame. The one micro-frame delay yields host controller periodic schedule and bus frame boundary relationship as illustrated in the following figure. This adjustment allows software to trivially schedule the periodic start and

complete-split transactions for full-and low-speed periodic endpoints, using the natural alignment of the periodic schedule interface. The reasons for selecting this phase-shift are beyond the scope of this specification.

The following figure illustrates how periodic schedule data structures relate to schedule frame boundaries and bus frame boundaries. To aid the presentation, two terms are defined: The host controller's view of the 1 msec boundaries is called H-Frames. The high-speed bus's view of the 1 msec boundaries is called B-Frames.

**Figure 41-10. Relationship of Periodic Schedule Frame Boundaries to Bus Frame Boundaries**

H-Frame boundaries for the host controller correspond to increments of  $FRINDEX[13:3]$ . Micro-frame numbers for the H-Frame are tracked by  $FRINDEX[2:0]$ . B-Frame boundaries are visible on the high-speed bus through changes in the SOF token's frame number. Micro-frame numbers on the high-speed bus are only derived from the SOF token's frame number (that is the high-speed bus sees eight SOFs with the same frame number value). H-Frames and B-Frames have the fixed relationship (that is B-Frames lag H-Frames by one micro-frame time) illustrated in the figure above. The host controller's periodic schedule is naturally aligned to H-Frames. Software schedules transactions for full- and low-speed periodic endpoints relative the H-Frames. The result is these transactions execute on the high-speed bus at exactly the right time for the USB 2.0 Hub periodic pipeline. As described in [USB Frame Index \( \$USB\_nFRINDEX\$ \)](#), the SOF Value can be implemented as a shadow register (in this example, called SOFV), which lags the  $FRINDEX$  register bits  $[13:3]$  by one micro-frame count. This lag behavior can be accomplished by incrementing  $FRINDEX[13:3]$  based on carry-out on the 7 to 0 increment of  $FRINDEX[2:0]$  and incrementing SOFV based on the transition of 0 to 1 of  $FRINDEX[2:0]$ .

Software is allowed to write to FRINDEX. [USB Frame Index \(USB\\_nFRINDEX\)](#) provides the requirements that software should adhere when writing a new value in FRINDEX.

The table below illustrates the required relationship between the value of FRINDEX and the value of SOFV.

**Table 41-40. Operation of FRINDEX and SOFV (SOF Value Register)**

Current			Next		
FRINDEX[F]	SOFV	FRINDEX[mF]	FRINDEX[F]	SOFV	FRINDEX[mF]
N	N	111b	N+1	N	000b

N+1	N+1	011b	N+1	N+1	100b
N+1	N+1	100b	N+1	N+1	101b
N+1	N+1	101b	N+1	N+1	110b
N+1	N+1	110b	N+1	N+1	111b

**NOTE**

Where [F] = [13:3]; [mF] = [2:0]

**41.5.3.6 Periodic Schedule**

The periodic schedule traversal is enabled or disabled through the Periodic Schedule Enable bit in the USB\_USBCMD register. If the Periodic Schedule Enable bit is set to zero, then the host controller simply does not try to access the periodic frame list through the USB\_PERIODICLISTBASE register. Likewise, when the Periodic Schedule Enable bit is one, then the host controller does use the USB\_PERIODICLISTBASE register to traverse the periodic schedule.

The host controller will not react to modifications to the Periodic Schedule Enable immediately. In order to eliminate conflicts with split transactions, the host controller evaluates the Periodic Schedule Enable bit only when FRINDEX[2:0] is zero. System software must not disable the periodic schedule if the schedule contains an active split transaction work item that spans the 000b micro-frame. These work items must be removed from the schedule before the Periodic Schedule Enable bit is written to zero.

The Periodic Schedule Status bit in the USB\_USBSTS register indicates status of the periodic schedule. System software enables (or disables) the periodic schedule by writing one (or zero) to the Periodic Schedule Enable bit in the USB\_USBCMD register. Software then can poll the Periodic Schedule Status bit to determine when the periodic

schedule has made the desired transition. Software must not modify the Periodic Schedule Enable bit unless the value of the Periodic Schedule Enable bit equals that of the Periodic Schedule Status bit.

The periodic schedule is used to manage all isochronous and interrupt transfer streams. The base of the periodic schedule is the periodic frame list. Software links schedule data structures to the periodic frame list to produce a graph of scheduled data structures. The graph represents an appropriate sequence of transactions.

The following figure illustrates isochronous transfers (using iTDs and siTDs) with a period of one are linked directly to the periodic frame list. Interrupt transfers (are managed with queue heads) and isochronous streams with periods other than one are linked following the period-one iTD/siTDs. Interrupt queue heads are linked into the frame list ordered by poll rate. Longer poll rates are linked first (for example, closest to the periodic frame list), followed by shorter poll rates, with queue heads with a poll rate of one, on the very end.

**Figure 41-11. Example Periodic Schedule**

### 41.5.3.7 Managing Isochronous Transfers Using iTDs

The structure of an iTD is presented in [Isochronous \(High-Speed\) Transfer Descriptor \(iTD\)](#). The four distinct sections to an iTD:

- The first field is the Next Link Pointer. This field is for schedule linkage purposes only.
- Transaction description array. This area is an eight-element array. Each element represents control and status information for one micro-frame's worth of transactions for a single high-speed isochronous endpoint.
- The buffer page pointer array is a 7-element array of physical memory pointers to data buffers. These are 4 K aligned pointers to physical memory.
- Endpoint capabilities. This area utilizes the unused low-order 12 bits of the buffer page pointer array. The fields in this area are used across all transactions executed for this iTD, including endpoint addressing, transfer direction, maximum packet size and high-bandwidth multiplier.

#### 41.5.3.7.1 Host Controller Operational Model for iTDs

The host controller uses FRINDEX register bits [12:3] to index into the periodic frame list. This means that the host controller visits each frame list element eight consecutive times before incrementing to the next periodic frame list element. Each iTD contains eight transaction descriptions, which map directly to FRINDEX register bits [2:0]. Therefore, each transaction descriptor corresponds to one micro-frame. Each iTD can span 8 micro-frames worth of transactions.

When the host controller fetches an iTD, it uses FRINDEX register bits [2:0] to index into the transaction description array.

If the active bit in the Status field of the indexed transaction description is set to zero, the host controller ignores the iTD and follows the Next pointer to the next schedule data structure.

When the indexed active bit is one, the host controller continues to parse the iTD. It stores the indexed transaction description and the general endpoint information (device address, endpoint number, maximum packet size, and so on.). It also uses the Page Select (PG) field to index the buffer pointer array, storing the selected buffer pointer and the next sequential buffer pointer. For example, if PG field is 0, then the host controller stores Page 0 and Page 1.

The host controller constructs a physical data buffer address by concatenating the current buffer pointer (as selected using the current transaction description's PG field) and the transaction description's Transaction Offset field. The host controller uses the endpoint addressing information and I/O-bit to execute a transaction to the appropriate endpoint. When the transaction is complete, the host controller clears the active bit and writes back any additional status information to the Status field in the currently selected transaction description.

The data buffer associated with the iTD must be virtually contiguous memory. Seven page pointers are provided to support eight high-bandwidth transactions regardless of the starting packet's offset alignment into the first page. A starting buffer pointer (physical memory address) is constructed by concatenating the page pointer (for example, page 0 pointer) selected by the active transaction descriptions' PG (for example, value: 00B) field with the transaction offset field. As the transaction moves data, the host controller must detect when an increment of the current buffer pointer crosses a page boundary. When this occurs the host controller simply replaces the current buffer pointer's page portion with the next page pointer (for example, page 1 pointer) and continues to move data. The size of each bus transaction is determined by the value in the Maximum Packet Size field. An iTD supports high-bandwidth pipes through the Mult (multiplier) field. When the Mult field is 1, 2, or 3, the host controller executes the specified number of Maximum Packet sized bus transactions for the endpoint in the current micro-frame. In other words, the Mult field represents a transaction count for the endpoint in the current micro-frame. If the Mult field is zero, the operation of the host controller is undefined. The transfer description is used to service all transactions indicated by the Mult field.

For OUT transfers, the value of the Transaction X Length field represents the total bytes to be sent during the micro-frame. The Mult field must be set by software to be consistent with Transaction X Length and Maximum Packet Size. The host controller sends the bytes in Maximum Packet Size'd portions. After each transaction, the host controller decrements its local copy of Transaction X Length by Maximum Packet Size. The number of bytes the host controller sends is always Maximum Packet Size or Transaction X Length, whichever is less. The host controller advances the transfer state in the transfer description, updates the appropriate record in the iTD and moves to the next schedule data structure. The maximum sized transaction supported is 3 x 1024 bytes.

For IN transfers, the host controller issues Mult transactions. It is assumed that software has properly initialized the iTD to accommodate all of the possible data. During each IN transaction, the host controller must use Maximum Packet Size to detect packet babble errors. The host controller keeps the sum of bytes received in the Transaction X Length field. After all transactions for the endpoint have completed for the micro-frame, Transaction X Length contains the total bytes received. If the final value of Transaction X Length is less than the value of Maximum Packet Size, then less data than was allowed for was received from the associated endpoint. This short packet condition does not set

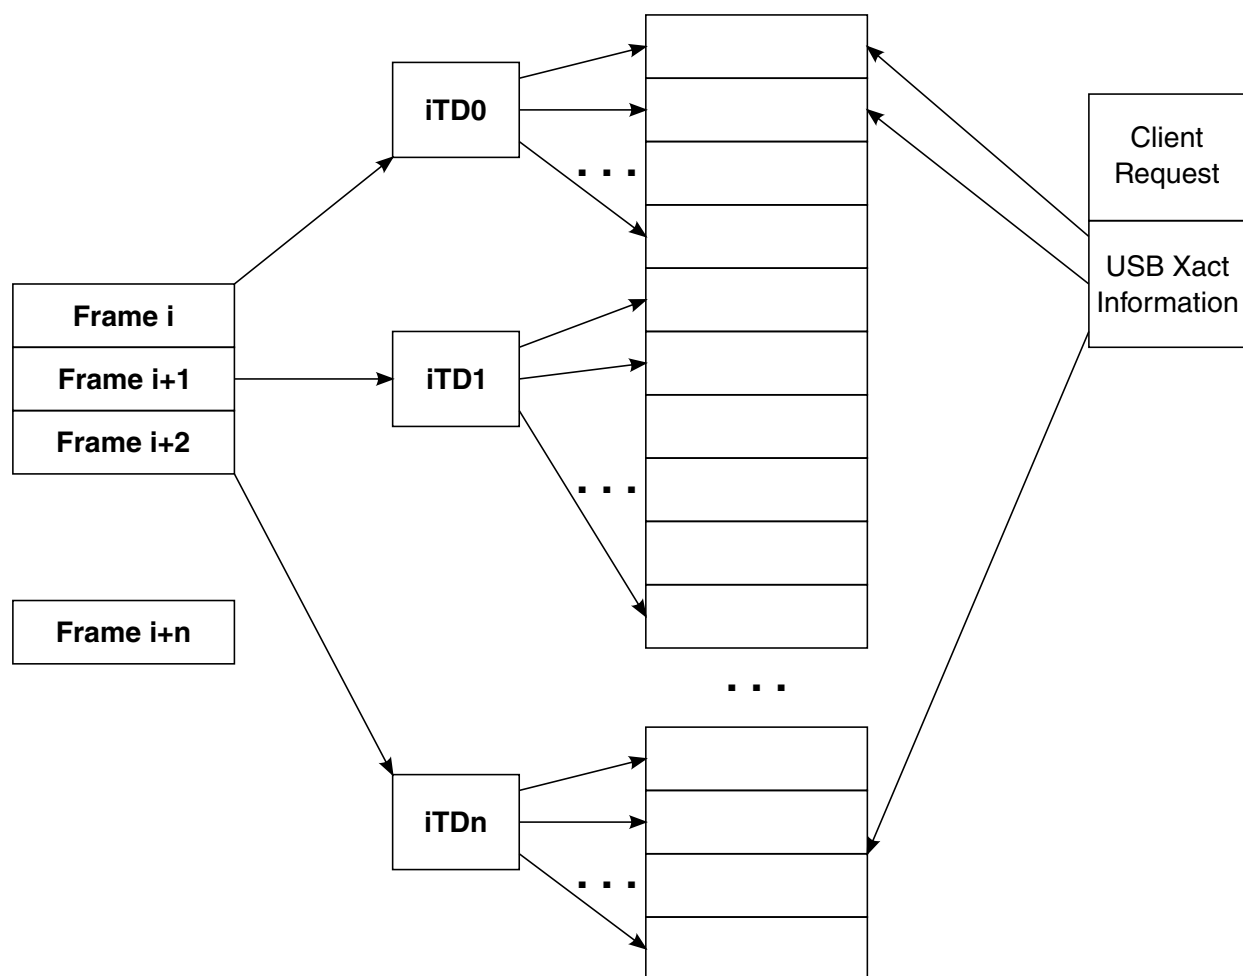

the USBINT bit in the USB\_USBSTS register to one. The host controller will not detect this condition. If the device sends more than Transaction X Length or Maximum Packet Size bytes (whichever is less), then the host controller sets the Babble Detected bit to one and set the Active bit to zero. Note, that the host controller is not required to update the iTD field Transaction X Length in this error scenario. If the Mult field is greater than one, then the host controller automatically executes the value of Mult transactions. The host controller will not execute all Mult transactions if:

- The endpoint is an OUT and Transaction X Length goes to zero before all the Mult transactions have executed (ran out of data), or
- The endpoint is an IN and the endpoint delivers a short packet, or an error occurs on a transaction before Mult transactions have been executed. The end of micro-frame may occur before all of the transaction opportunities have been executed. When this happens, the transfer state of the transfer description is advanced to reflect the progress that was made, the result written back to the iTD and the host controller proceeds to processing the next micro-frame. Refer to Appendix D for a table summary of the host controller required behavior for all the high-bandwidth transaction cases.

#### 41.5.3.7.2 Software Operational Model for iTDs

A client buffer request to an isochronous endpoint may span 1 to N micro-frames. When N is larger than one, system software may have to use multiple iTDs to read or write data with the buffer (if N is larger than eight, it must use more than one iTD).

The following figure illustrates the simple model of how a client buffer is mapped by system software to the periodic schedule (that is the periodic frame list and a set of iTDs). On the right is the client description of its request. The description includes a buffer base address plus additional annotations to identify which portions of the buffer should be used with each bus transaction. In the middle is the iTD data structures used by the system software to service the client request. Each iTD can be initialized to service up to 24 transactions, organized into eight groups of up to three transactions each. Each group maps to one micro-frame's worth of transactions. The EHCI controller does not provide per-transaction results within a micro-frame. It treats the per-micro-frame transactions as a single logical transfer. On the left is the host controller's frame list. System software establishes references from the appropriate locations in the frame list to each of the appropriate iTDs. If the buffer is large, then system software can use a small set of iTDs to service the entire buffer. System software can activate the transaction description records (contained in each iTD) in any pattern required for the particular data stream.

**Figure 41-12. Example Association of iTDs to Client Request Buffer**

As noted above, the client request includes a pointer to the base of the buffer and offsets into the buffer to annotate which buffer sections are to be used on each bus transaction that occurs on this endpoint. System software must initialize each transaction description in an iTD to ensure it uses the correct portion of the client buffer. For example, for each transaction description, the PG field is set to index the correct physical buffer page pointer and the Transaction Offset field is set relative to the correct buffer pointer page (for example, the same one referenced by the PG field). When the host controller executes a transaction it selects a transaction description record based on FRINDEX[2:0]. It then uses the current Page Buffer Pointer (as selected by the PG field) and concatenates to the transaction offset field. The result is a starting buffer address for the transaction. As the host controller moves data for the transaction, it must watch for a page wrap condition and properly advance to the next available Page Buffer Pointer. System software must not use the Page 6 buffer pointer in a transaction description where the length of the transfer wraps a page boundary. Doing so yields undefined behavior. The host controller hardware is not required to 'alias' the page selector to Page zero. USB 2.0 isochronous

endpoints can specify a period greater than one. Software can achieve the appropriate scheduling by linking iTDs into the appropriate frames (relative to the frame list) and by setting appropriate transaction description elements active bits to one.

#### 41.5.3.7.2.1 Periodic scheduling threshold

The Isochronous Scheduling Threshold field in the USB\_HCCPARAMS capability register is an indicator to system software as to how the host controller pre-fetches and effectively caches schedule data structures.

It is used by system software when adding isochronous work items to the periodic schedule. The value of this field indicates to system software the minimum distance it can update isochronous data (relative to the current location of the host controller execution in the periodic list) and still have the host controller process them.

The iTD and siTD data structures each describe 8 micro-frames worth of transactions. The host controller is allowed to cache one (or more) of these data structures in order to reduce memory traffic. Three basic caching models that account for the fact the isochronous data structures span 8 micro-frames. The three caching models are: no caching, micro-frame caching and frame caching.

When software is adding new isochronous transactions to the schedule, it always performs a read of the USB\_FRINDEX register to determine the current frame and micro-frame the host controller is currently executing. Of course, there is no information about where in the micro-frame the host controller is, so a constant uncertainty-factor of one micro-frame has to be assumed. Combining the knowledge of where the host controller is executing with the knowledge of the caching model allows the definition of simple algorithms for how closely software can reliably work to the executing host controller.

No caching is indicated with a value of zero in the Isochronous Scheduling Threshold field. The host controller may pre-fetch data structures during a periodic schedule traversal (per micro-frame) but always dumps any accumulated schedule state at the end of the micro-frame. At the appropriate time relative to the beginning of every micro-frame, the host controller always begins schedule traversal from the frame list. Software can use the value of the USB\_FRINDEX register (plus the constant 1 uncertainty-factor) to determine the approximate position of the executing host controller. When no caching is selected, software can add an isochronous transaction as near as 2 micro-frames in front of the current executing position of the host controller.

Frame caching is indicated with a non-zero value in bit [7] of the Isochronous Scheduling Threshold field. In the frame-caching model, system software assumes that the host controller caches one (or more) isochronous data structures for an entire frame (8 micro-frames). Software uses the value of the USB\_FRINDEX register (plus the constant 1

uncertainty) to determine the current micro-frame/frame (assume modulo 8 arithmetic in adding the constant 1 to the micro-frame number). For any current frame N, if the current micro-frame is 0 to 6, then software can safely add isochronous transactions to Frame N + 1. If the current micro-frame is 7, then software can add isochronous transactions to Frame N + 2.

Micro-frame caching is indicated with a non-zero value in the least-significant 3 bits of the Isochronous Scheduling Threshold field. System software assumes the host controller caches one or more periodic data structures for the number of micro-frames indicated in the Isochronous Scheduling Threshold field. For example, if the count value were 2, then the host controller keeps a window of 2 micro-frames worth of state (current micro-frame, plus the next) on-chip. On each micro-frame boundary, the host controller releases the current micro-frame state and begins accumulating the next micro-frame state.

### 41.5.3.8 Asynchronous Schedule

The Asynchronous schedule traversal is enabled or disabled through the Asynchronous Schedule Enable bit in the USB\_USBCMD register.

If the Asynchronous Schedule Enable bit is set to zero, then the host controller simply does not try to access the asynchronous schedule through the USB\_ASYNCLISTADDR register. Likewise, when the Asynchronous Schedule Enable bit is one, then the host controller does use the USB\_ASYNCLISTADDR register to traverse the asynchronous schedule. Modifications to the Asynchronous Schedule Enable bit are not necessarily immediate. Rather the new value of the bit is taken into consideration the next time the host controller needs to use the value of the USB\_ASYNCLISTADDR register to get the next queue head.

The Asynchronous Schedule Status bit in the USB\_USBSTS register indicates status of the asynchronous schedule. System software enables (or disables) the asynchronous schedule by writing one (or zero) to the Asynchronous Schedule Enable bit in the USB\_USBCMD register. Software then can poll the Asynchronous Schedule Status bit to determine when the asynchronous schedule has made the desired transition. Software must not modify the Asynchronous Schedule Enable bit unless the value of the Asynchronous Schedule Enable bit equals that of the Asynchronous Schedule Status bit.

The asynchronous schedule is used to manage all Control and Bulk transfers. Control and Bulk transfers are managed using queue head data structures. The asynchronous schedule is based at the USB\_ASYNCLISTADDR register. The default value of the USB\_ASYNCLISTADDR register after reset is undefined and the schedule is disabled when the Asynchronous Schedule Enable bit is zero.

Software may only write this register with defined results when the schedule is disabled. For example, Asynchronous Schedule Enable bit in the USB\_USBCMD and the Asynchronous Schedule Status bit in the USB\_USBSTS register are zero. System software enables execution from the asynchronous schedule by writing a valid memory address (of a queue head) into this register. Then software enables the asynchronous schedule by setting the Asynchronous Schedule Enable bit to one. The asynchronous schedule is actually enabled when the Asynchronous Schedule Status bit is one.

When the host controller begins servicing the asynchronous schedule, it begins by using the value of the USB\_ASYNCLISTADDR register. It reads the first referenced data structure and begins executing transactions and traversing the linked list as appropriate. When the host controller completes processing the asynchronous schedule, it retains the value of the last accessed queue head's horizontal pointer in the USB\_ASYNCLISTADDR register. Next time the asynchronous schedule is accessed, this is the first data structure that is serviced. This provides round-robin fairness for processing the asynchronous schedule.

A host controller completes processing the asynchronous schedule when one of the following events occur:

- The end of a micro-frame occurs.
- The host controller detects an empty list condition (see [Empty Asynchronous Schedule Detection](#) )
- The schedule has been disabled through the Asynchronous Schedule Enable bit in the USB\_USBCMD register.

The queue heads in the asynchronous list are linked into a simple circular list as shown in [Figure 41-7](#). Queue head data structures are the only valid data structures that may be linked into the asynchronous schedule. An isochronous transfer descriptor (iTd or siTD) in the asynchronous schedule yields undefined results.

The maximum packet size field in a queue head is sized to accommodate the use of this data structure for all non-isochronous transfer types. The USB Specification, Revision 2.0 specifies the maximum packet sizes for all transfer types and transfer speeds. System software should always parameterize the queue head data structures according to the core specification requirements.

#### 41.5.3.8.1 Adding Queue Heads to Asynchronous Schedule

This is a software requirement section.

There are two independent events for adding queue heads to the asynchronous schedule. The first is the initial activation of the asynchronous list. The second is inserting a new queue head into an activated asynchronous list.

Activation of the list is simple. System software writes the physical memory address of a queue head into the USB\_ASYNC\_LIST\_ADDR register, then enables the list by setting the Asynchronous Schedule Enable bit in the USB\_USBCMD register to one.

When inserting a queue head into an active list, software must ensure that the schedule is always coherent from the host controllers' point of view. This means that the system software must ensure that all queue head pointer fields are valid. For example, qTD pointers have T-Bits set to one or reference valid qTDs and the Horizontal Pointer references a valid queue head data structure. The following algorithm represents the functional requirements:

```

InsertQueueHead (pQHeadCurrent, pQueueHeadNew)
--
-- Requirement: all inputs must be properly initialized.
--
-- pQHeadCurrent is a pointer to a queue head that is
-- already in the active list
-- pQHeadNew is a pointer to the queue head to be added
--
-- This algorithm links a new queue head into a existing
-- list
--
pQueueHeadNew.HorizontalPointer = pQueueHeadCurrent.HorizontalPointer
pQueueHeadCurrent.HorizontalPointer = physicalAddressOf (pQueueHeadNew)
End InsertQueueHead

```

### 41.5.3.8.2 Removing Queue Heads from Asynchronous Schedule

This is a software requirement section.

There are two independent events for removing queue heads from the asynchronous schedule. The first is shutting down (deactivating) the asynchronous list. The second is extracting a single queue head from an activated list.

Software deactivates the asynchronous schedule by setting the Asynchronous Schedule Enable bit in the USB\_USBCMD register to zero. Software can determine when the list is idle when the Asynchronous Schedule Status bit in the USB\_USBSTS register is zero. The normal mode of operation is that software removes queue heads from the asynchronous schedule without shutting it down. Software must not remove an active queue head from the schedule. Software should first deactivate all active qTDs, wait for the queue head to go inactive, then remove the queue head from the asynchronous list. Software removes a queue head from the asynchronous list through the following algorithm. As illustrated, the unlinking is quite easy. Software merely must ensure all of the link pointers reachable by the host controller are kept consistent.

```

UnlinkQueueHead (pQHeadPrevious, pQueueHeadToUnlink, pQHeadNext)
--
-- Requirement: all inputs must be properly initialized.
--
-- pQHeadPrevious is a pointer to a queue head that
-- references the queue head to remove
-- pQHeadToUnlink is a pointer to the queue head to be

```

## USB Operation Model

```
-- removed
-- pQheadNext is a pointer to a queue head still in the
-- schedule. Software provides this pointer with the
-- following strict rules:
--     if the host software is one queue head, then
--     pQheadNext must be the same as
--     QueueheadToUnlink.HorizontalPointer. If the host
--     software is unlinking a consecutive series of
--     queue heads, QheadNext must be set by software to
--     the queue head remaining in the schedule.
--
-- This algorithm unlinks a queue head from a circular list
--
pQueueHeadPrevious.HorizontalPointer = pQueueHeadToUnlink.HorizontalPointer
pQueueHeadToUnlink.HorizontalPointer = pQheadNext
```

End UnlinkQueueHead

If software removes the queue head with the H-bit set to one, it must select another queue head still linked into the schedule and set its H-bit to one. This should be completed before removing the queue head. The requirement is that software keep one queue head in the asynchronous schedule, with its H-bit set to one. At the point software has removed one or more queue heads from the asynchronous schedule, it is unknown whether the host controller has a cached pointer to them. Similarly, it is unknown how long the host controller might retain the cached information, as it is implementation dependent and may be affected by the actual dynamics of the schedule load. Therefore, once software has removed a queue head from the asynchronous list, it must retain the coherency of the queue head (link pointers, and so on). It cannot disturb the removed queue heads until it knows that the host controller does not have a local copy of a pointer to any of the removed data structures.

The method software uses to determine when it is safe to modify a removed queue head is to handshake with the host controller. The handshake mechanism allows software to remove items from the asynchronous schedule, then execute a simple, lightweight handshake that is used by software as a key that it can free (or reuse) the memory associated the data structures it has removed from the asynchronous schedule.

The handshake is implemented with three bits in the host controller. The first bit is a command bit (Interrupt on Async Advance Doorbell bit in the USB\_USBCMD register) that allows software to inform the host controller that something has been removed from its asynchronous schedule. The second bit is a status bit (Interrupt on Async Advance bit in the USB\_USBSTS register) that the host controller sets after it has released all on-chip state that may potentially reference one of the data structures just removed. When the host controller sets this status bit to one, it also sets the command bit to zero. The third bit is an interrupt enable (Interrupt on Async Advance bit in the USB\_USBINTR register) that is matched with the status bit. If the status bit is one and the interrupt enable bit is one, then the host controller asserts a hardware interrupt.

The figure below illustrates a general example. In this example, consecutive queue heads (B and C) are unlinked from the schedule using the algorithm above. Before the unlink operation, the host controller has a copy of queue head A.

The unlink algorithm requires that as software unlinks each queue head, the unlinked queue head is loaded with the address of a queue head that remains in the asynchronous schedule.

When the host controller observes that doorbell bit being set to one, it makes a note of the local reachable schedule information. In this example, the local reachable schedule information includes both queue heads (A and B). It is sufficient that the host controller can set the status bit (and clear the doorbell bit) as soon as it has traversed beyond current reachable schedule information (that is traversed beyond queue head (B) in this example). The following figure illustrates the generic queue head unlink scenario.

**Figure 41-13. Generic Queue Head Unlink Scenario**

Alternatively, a host controller implementation is allowed to traverse the entire asynchronous schedule list (for example, observed the head of the queue (twice)) before setting the Advance on Async status bit to one.

Software may re-use the memory associated with the removed queue heads after it observes the Interrupt on Async Advance status bit is set to one, following assertion of the doorbell. Software should acknowledge the Interrupt on Async Advance status as indicated in the `USB_USBSTS` register, before using the doorbell handshake again.

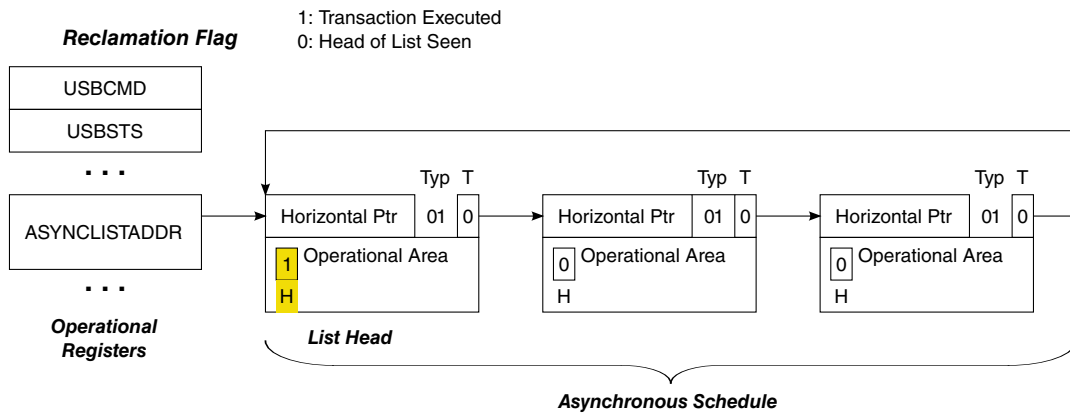

### 41.5.3.8.3 Empty Asynchronous Schedule Detection

The Enhanced Host Controller Interface uses two bits to detect when the asynchronous schedule is empty.

The queue head data structure (see [Table 41-26](#)) defines an *H-bit* in the queue head, which allows software to mark a queue head as being the *head* of the reclaim list. The Enhanced Host Controller Interface also keeps a 1-bit flag in the USB\_USBSTS register (*Reclamation*) that is set to zero when the Enhanced Interface Host Controller observes a queue head with the H-bit set to one. The reclamation flag in the status register is set to one when any USB transaction from the asynchronous schedule is executed (or whenever the asynchronous schedule starts, see [Asynchronous schedule traversal: Start Event](#)).

If the Enhanced Host Controller Interface ever encounters an *H-bit* of one and a *Reclamation* bit of zero, the EHCI controller simply stops traversal of the asynchronous schedule.

An example illustrating the H-bit in a schedule is shown in the following figure.

**Figure 41-14. Asynchronous Schedule List w/Annotation to Mark Head of List**

Software must ensure there is at most one queue head with the *H-bit* set to one, and that it is always coherent with respect to the schedule.

#### 41.5.3.8.4 Restarting Asynchronous Schedule Before EOF

There are many situations where the host controller will detect an empty list *long* before the end of the micro-frame.

It is important to remember that under many circumstances the schedule traversal has stopped due to Nak/Nyet responses from all endpoints.

An example of particular interest is when a start-split for a bulk endpoint occurs early in the micro-frame. Given the EHCI simple traversal rules, the complete-split for that transaction may Nak/Nyet out very quickly. If it is the only item in the schedule, then the host controller ceases traversal of the Asynchronous schedule very early in the micro-frame. In order to provide reasonable service to this endpoint, the host controller should issue the complete-split before the end of the current micro-frame, instead of waiting

until the next micro-frame. When the reason for host controller idling asynchronous schedule traversal is because of empty list detection, it is mandatory the host controller implement a 'waking' method to resume traversal of the asynchronous schedule. An example method is described below.

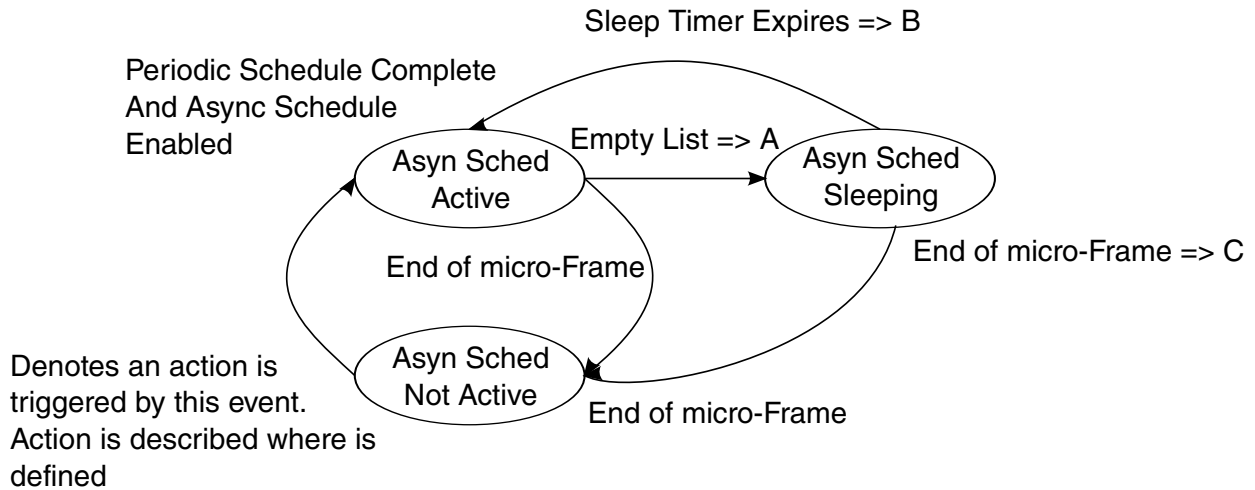

#### 41.5.3.8.4.1 Example Method for Restarting Asynchronous Schedule Traversal

The reason for idling the host controller when the list is empty is to keep the host controller from unnecessarily occupying too much memory bandwidth. The question is: *how long should the host controller stay idle before restarting?*

The answer in this example is based on deriving a manifest constant, which is the amount of time the host controller will stay idle before restarting traversal. In this example, the manifest constant is called *AsyncSchedSleepTime*, and has a value of 10  $\mu$ sec. The value is derived based on the analysis in [Example Derivation for AsyncSchedSleepTime](#). The traversal algorithm is simple:

- Traverse the Asynchronous schedule until the either an End-Of-micro-Frame event occurs, or an empty list is detected. If the event is an End-of-micro-Frame, go attempt to traverse the Periodic schedule. If the event is an empty list, then set a sleep timer and go to a *schedule sleep* state.
- When the sleep timer expires, set working context to the Asynchronous Schedule start condition and go to *schedule active* state. The start context allows the HC to reload *Nakcnt* fields, and so on. So the HC has a chance to run for more than one iteration through the schedule.

This process simply repeats itself each micro-frame. The figure below illustrates a sample state machine to manage the active and sleep states of the Asynchronous Schedule traversal policy. There are three states: Actively traversing the Asynchronous schedule, Sleeping, and Not Active. The last two are similar in terms of interaction with the Asynchronous schedule, but the Not Active state means that the host controller is busy with the Periodic schedule or the Asynchronous schedule is not enabled. The Sleeping state is specifically a special state where the host controller is just waiting for a period of time before resuming execution of the Asynchronous schedule.

**Figure 41-15. Example State Machine for Managing Asynchronous Schedule Traversal**

The actions referred to in the figure above are defined in the following table.

**Table 41-41. Asynchronous Schedule SM Transition Actions**

Action	Action Description Label
A	On detection of the empty list, the host controller sets the <i>AsynchronousTraversalSleepTimer</i> to <i>AsyncSchedSleepTime</i> .
B	When the <i>AsynchronousTraversalSleepTimer</i> expires, the host controller sets the <i>Reclamation</i> bit in the USBSTS register to one and moves the Nak Counter reload state machine to WaitForListHead (see <a href="#">Nak Count Reload Control</a> ).
C	The host controller cancels the sleep timer ( <i>AsynchronousTraversalSleepTimer</i> ).

**41.5.3.8.4.2 Async Sched Not Active**

This is the initial state of the traversal state machine after a host controller reset. The traversal state machine does not leave this state when the *Asynchronous Schedule Enable* bit in the USB\_USBCMD register is zero.

This state is entered from Async Sched Active or Async Sched Sleeping states when the end-of-micro-frame event is detected.

**41.5.3.8.4.3 Async Sched Active**

This state is entered from the Async Sched Not Active state when the periodic schedule is not active. It is also entered from the Async Sched Sleeping states when the *AsynchrhonousTraversalSleepTimer* expires. On every transition into this state, the host controller sets the *Reclamation* bit in the USB\_USBSTS register to one.

While in this state, the host controller continually traverses the asynchronous schedule until either the end of micro-frame or an empty list condition is detected.

#### 41.5.3.8.4.4 Async Sched Sleeping

The state is entered from the Async Sched Active state when a schedule empty condition is detected. On entry to this state, the host controller sets the *AsynchronousTraversalSleepTimer* to *AsyncSchedSleepTime*.

#### 41.5.3.8.4.5 Example Derivation for AsyncSchedSleepTime

The derivation is based on analysis of what work the host controller could be doing next.

It assumes the host controller does not keep any state about what work is possibly pending in the asynchronous schedule. The schedule could contain any mix of the possible combinations of high- full- or low-speed control and bulk requests.

The table below summarizes some of the typical 'next transactions' that could be in the schedule, and the amount of time (for example *footprint*, or *wall clock*) the transaction takes to complete.

**Table 41-42. Typical Low-/Full-speed Transaction Times**

Transaction Attributes		Footprint (time)	Description
Speed	HS	11.9 ms	Maximum foot print for a worst-case, full-sized bulk data transaction.
Size	512	9.45 ms	Maximum footprint for an approximate best-case, full-sized bulk data transaction.
Type	Bulk		
Speed	FS	~50 ms	Approximate typical for full-sized bulk data. An 8-byte low-speed is about 2x, or between 90 and 100 ms.
Size	64		
Type	Bulk		
Speed	FS	~12 ms	Approximate typical for 8-byte bulk/control (that is setup)
Size	8		
Type	Cntrl		

A *AsyncSchedSleepTime* value of 10  $\mu$ s provides a reasonable relaxation of the system memory load and still provides a good level of service for the various transfer types and payload sizes. For example, say we detect an empty list after issuing a start-split for a 64-byte full-speed bulk request. Assuming this is the only thing in the list, the host controller gets the results of the full-speed transaction from the hub during the fifth complete-split request. If the full-speed transaction was an IN and it nak'd, the 10  $\mu$ s sleep period would allow the host controller to get the NAK results on the first complete-split.

#### 41.5.3.8.5 Asynchronous schedule traversal: *Start Event*

Once the HC has *idled* itself through the empty schedule detection (Section 0), it will naturally *activate* and begin processing from the Periodic Schedule at the beginning of each micro-frame.

In addition, it may have idled itself early in a micro-frame. When this occurs (idles early in the micro-frame) the HC must occasionally *re-activate* during the micro-frame and traverse the asynchronous schedule to determine whether any progress can be made. The requirements and method for this restart are described in [Restarting Asynchronous Schedule Before EOF](#). Asynchronous schedule *Start Events* are defined to be:

- Whenever the host controller transitions from the periodic schedule to the asynchronous schedule. If the periodic schedule is disabled and the asynchronous schedule is enabled, then the beginning of the micro-frame is equivalent to the transition from the periodic schedule, or
- The asynchronous schedule traversal restarts from a sleeping state (see [Restarting Asynchronous Schedule Before EOF](#)).

#### 41.5.3.8.6 Reclamation Status Bit (USBSTS Register)

The operation of the empty asynchronous schedule detection feature (see [Empty Asynchronous Schedule Detection](#)) depends on the proper management of the *Reclamation* bit in the USB\_USBSTS register. The host controller tests for an empty schedule just after it fetches a new queue head while traversing the asynchronous schedule (see [Fetch Queue Head](#)).

The host controller is required to set the *Reclamation* bit to one whenever an asynchronous schedule traversal *Start Event*, as documented in [Asynchronous schedule traversal: Start Event](#), occurs. The *Reclamation* bit is also set to one whenever the host controller executes a transaction while traversing the asynchronous schedule (see [Execute Transaction](#)). The host controller sets the *Reclamation* bit to zero whenever it finds a queue head with its *H-bit* set to one. Software should only set a queue head's *H-bit* if the queue head is in the asynchronous schedule. If software sets the *H-bit* in an interrupt queue head to one, the resulting behavior is undefined. The host controller may set the *Reclamation* bit to zero when executing from the periodic schedule.

#### 41.5.3.9 Operational Model for Nak Counter

This section describes the operational model for the *NakCnt* field defined in a queue head.

See [Queue Head Initialization](#) for more information. Software should not use this feature for interrupt queue heads. This rule is not required to be enforced by the host controller.

USB protocol has built-in flow control through the Nak response by a device. There are several scenarios, beyond the Ping feature, where an endpoint may naturally Nak or Nyet the majority of the time. An example is the host controller management of the split transaction protocol for control and bulk endpoints. All bulk endpoints (High- or Full-speed) are serviced through the same asynchronous schedule. The time between the *Start-split* transaction and the first *Complete-split* transaction could be very short (that is like when the endpoint is the only one in the asynchronous schedule). The hub NYETs (effectively Naks) the *Complete-split* transaction until the classic transaction is complete. This could result in the host controller thrashing memory, repeatedly fetching the queue head and executing the transaction to the Hub, which does not complete until after the transaction on the classic bus completes.

The two component fields in a queue head to support the throttling feature: a counter field (*NakCnt*), and a counter reload field (*RL*). *NakCnt* is used by the host controller as one of the criteria to determine whether or not to execute a transaction to the endpoint. The two operational modes associated with this counter:

- Not Used- This mode is set when the *RL* field is zero. The host controller ignores the *NakCnt* field for any execution of transactions through a queue head with an *RL* field of zero. Software must use this selection for interrupt endpoints.
- Nak Throttle Mode- This mode is selected when the *RL* field is non-zero. In this mode, the value in the *NakCnt* field represents the maximum number of Nak or Nyet responses the host controller tolerates on each endpoint. In this mode, the HC decrements the *NakCnt* field based on the token/handshake criteria listed in the table below. The host controller must reload *NakCnt* when the endpoint successfully moves data (for example, policy to reward device for moving data).

The following table describes the *NakCnt* field adjustment rules.

**Table 41-43. NakCnt Field Adjustment Rules**

Token	Handshake	
	Handshake NAK	NYET
IN/PING	decrement <i>NakCnt</i>	N/A (protocol error)
OUT	decrement <i>NakCnt</i>	No Action <sup>1</sup> Start
Split	decrement <i>NakCnt</i>	N/A (protocol error)
Complete Split	No Action	Decrement <i>NakCnt</i>

1. Recommended behavior on this response is to reload *NakCnt*

In summary, system software enables the counter by setting the reload field (*RL*) to a non-zero value. The host controller may execute a transaction if *NakCnt* is non-zero. The host controller does not execute a transaction if *NakCnt* is zero. The reload mechanism is described in detail in [Nak Count Reload Control](#) .

### NOTE

When all queue heads in the Asynchronous Schedule either exhausts all transfers or all *NakCnt*'s go to zero, then the host controller detects an empty Asynchronous Schedule and idle schedule traversal (see [Empty Asynchronous Schedule Detection](#) ).

Any time the host controller begins a new traversal of the Asynchronous Schedule, a *Start Event* is assumed, see [Asynchronous schedule traversal: Start Event](#). Every time a Start-Event occurs, the Nak Count reload procedure is enabled.

#### 41.5.3.9.1 Nak Count Reload Control

When the host controller reaches the *Execute Transaction* state for a queue head (meaning that it has an active operational state), it checks to determine whether the *NakCnt* field should be reloaded from *RL* (see [Execute Transaction](#) ). If the answer is yes, then *RL* is copied into *NakCnt*. After the reload or if the reload is not active, the host controller evaluates whether to execute the transaction.

The host controller must reload nak counters (*NakCnt* see [Table 41-26](#)) in queue heads during the first pass through the reclamation list after an asynchronous schedule Start Event (see [Asynchronous schedule traversal: Start Event](#) for the definition of the Start Event). The Asynchronous Schedule should have at most one queue head marked as the head (see [Figure 41-14](#)).

The following figure illustrates an example state machine that satisfies the operational requirements of the host controller detecting the first pass through the Asynchronous Schedule. This state machine is maintained internal to the host controller and is only used to gate reloading of the nak counter during the queue head traversal state: *Execute Transaction* (see the figure below). The host controller does not perform the nak counter reload operation if the *RL* field (see [Table 41-26](#)) is set to zero.

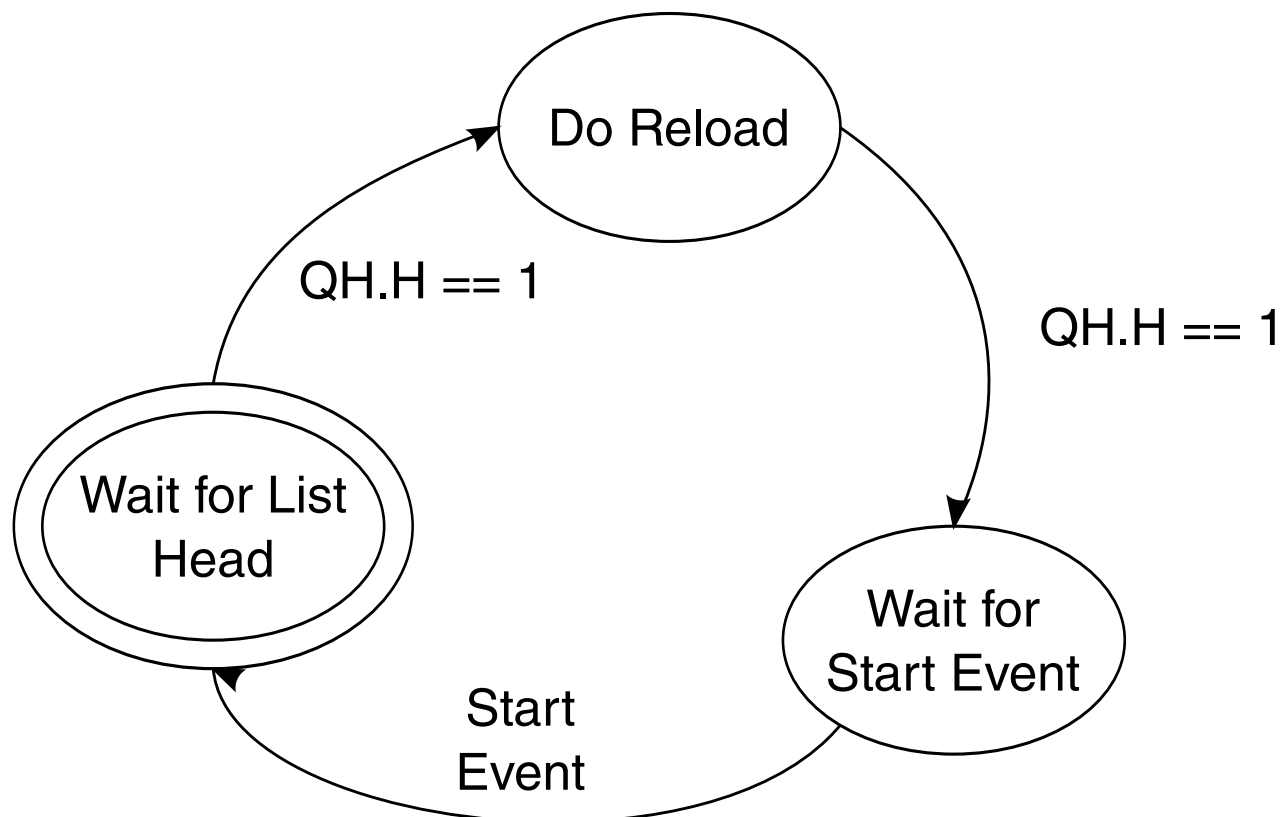

Figure 41-16. Example HC State Machine for Controlling Nak Counter Reloads

#### 41.5.3.9.1.1 Wait for List Head

This is the initial state.

The state machine enters this state from Wait for Start Event when a start event as defined in [Asynchronous schedule traversal: Start Event](#) occurs.

The purpose of this state is to wait for the first observation of the head of the Asynchronous Schedule.

This occurs when the host controller fetches a queue head whose *H-bit* is set to one.

#### 41.5.3.9.1.2 Do Reload

This state is entered from the Wait for List Head state when the host controller fetches a queue head with the *H-bit* set to one. While in this state, the host controller performs nak counter reloads for every queue head visited that has a non-zero nak reload value (*RL*) field.

### 41.5.3.9.1.3 Wait for Start Event

This state is entered from the *Do Reload* state when a queue head with the *H-bit* set to one is fetched. While in this state, the host controller does not perform nak counter reloads.

## 41.5.3.10 Managing Control/Bulk/Interrupt Transfers through Queue Heads

This section presents an overview of how the host controller interacts with queuing data structures.

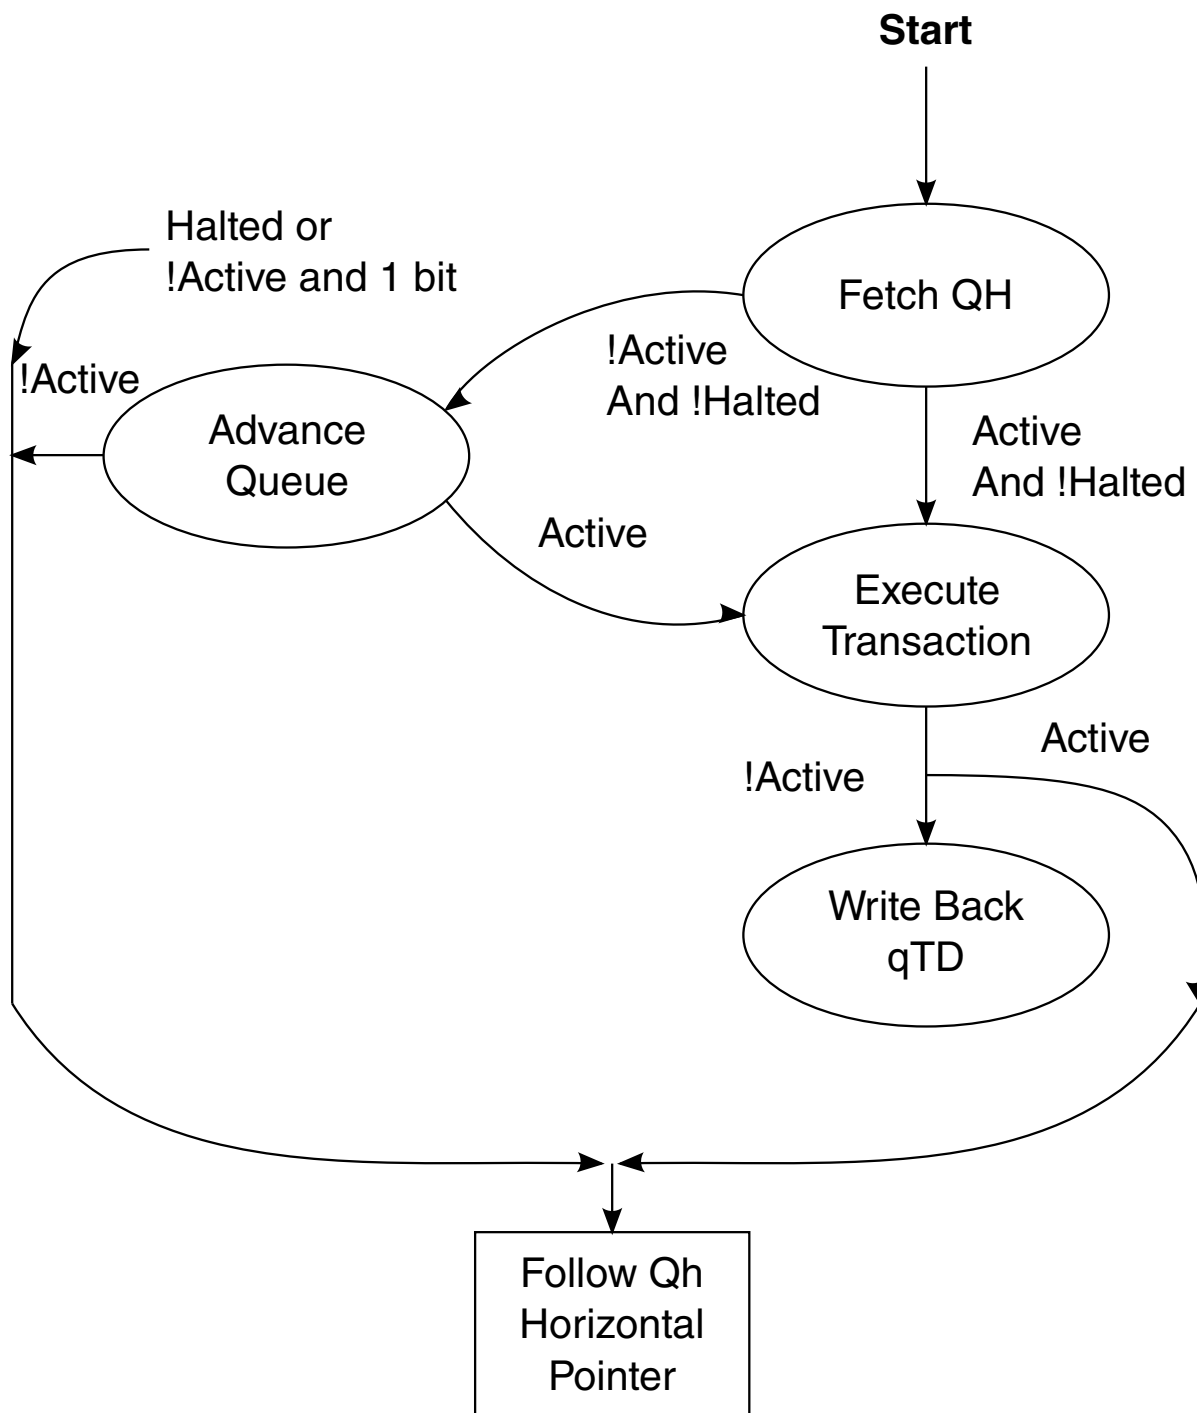

Queue heads use the Queue Element Transfer Descriptor (qTD) structure. One queue head is used to manage the data stream for one endpoint. The queue head structure contains static endpoint characteristics and capabilities. It also contains a working area from where individual bus transactions for an endpoint are executed (see Overlay area defined in [Table 41-26](#)). Each qTD represents one or more bus transactions, which is defined in the context of this specification as a *transfer*.

The general processing model for the host controller's use of a queue head is simple:

- read a queue head,
- execute a transaction from the overlay area,
- write back the results of the transaction to the overlay area,
- move to the next queue head.

If the host controller encounters errors during a transaction, the host controller sets one (or more) of the error reporting bits in the queue head's *Status* field. The *Status* field accumulates all errors encountered during the execution of a qTD (for example, the error bits in the queue head *Status* field are 'sticky' until the transfer (qTD) has completed). This state is always written back to the source qTD when the transfer is complete. On transfer (for example, buffer or halt conditions) boundaries, the host controller must auto-advance (without software intervention) to the next qTD. Additionally, the hardware must be able to halt the queue so no additional bus transactions occurs for the endpoint and the host controller does not advance the queue.

An example host controller operational state machine of a queue head traversal is illustrated in the following figure. This state machine is a model for how a host controller should traverse a queue head. The host controller must be able to advance the queue from the *Fetch QH* state in order to avoid all hardware/software race conditions. This simple mechanism allows software to simply link qTDs to the queue head and *activate* them, then the host controller always *find* them if/when they are reachable. The figure below illustrates the Host Controller Queue Head Traversal State Machine.

**Figure 41-17. Host Controller Queue Head Traversal State Machine**

This traversal state machine applies to all queue heads, regardless of transfer type or whether split transactions are required. The following sections describe each state. Each state description describes the entry criteria. The Execute Transaction state (see [Execute](#)

[Transaction](#) ) describes the basic requirements for all endpoints. [Split Transactions for Asynchronous Transfers](#) and [Split Transaction Interrupt](#) describe details of the required extensions to the Execute Transaction state for endpoints requiring split transactions.

### NOTE

Prior to software placing a queue head into either the periodic or asynchronous list, software must ensure the queue head is properly initialized. Minimally, the queue head should be initialized to the following (see Section Queue Head for layout of a queue head):

Valid static endpoint state.

- For the very first use of a queue head, software may zero-out the queue head transfer overlay, then set the *Next qTD Pointer* field value to reference a valid qTD.

#### 41.5.3.10.1 Fetch Queue Head

A queue head can be referenced from the physical address stored in the ASYNCLISTADDR Register (see [Next Asynch. Address \(USB\\_nASYNCLISTADDR\)](#))/ [Endpoint List Address \(USB\\_nENDPTLISTADDR\)](#) Additionally, it may be referenced from the *Next LinkPointer* field of an iTD, siTD, FSTN or another Queue Head. If the referencing link pointer has the *Typ* field set to indicate a queue head, it is assumed to reference a queue head structure as defined in [Table 41-26](#).

While in this state, the host controller performs operations to implement empty schedule detection (see [Empty Asynchronous Schedule Detection](#) ) and Nak Counter reloads (see [Operational Model for Nak Counter](#)). After the queue head has been fetched, the host controller conducts the following queries for empty schedule detection:

- If queue head is not an interrupt queue head (that is *S-mask* is zero), and
- The *H-bit* is one, and
- The *Reclamation* bit in the USBSTS register is zero.

When these criteria are met, the host controller stops traversing the asynchronous list (as described in [Empty Asynchronous Schedule Detection](#) ). When the criteria are not met, the host controller continues schedule traversal. If the queue head is not an interrupt and the *H-bit* is one and the *Reclamation* bit is one, then the host controller sets the *Reclamation* bit in the USBSTS register to zero before completing this state. The operations for reloading of the Nak Counter are described in detail in [Operational Model for Nak Counter](#).

This state is complete when the queue head has been read on-chip.

### 41.5.3.10.2 Advance Queue

To advance the queue, the host controller must find the next qTD, adjust pointers, perform the overlay and write back the results to the queue head.

This state is entered from the FetchQHD state if the overlay *Active* and *Halt* bits are set to zero. On entry to this state, the host controller determines which next pointer to use to fetch a qTD, fetches a qTD and determines whether or not to perform an overlay.

#### NOTE

If the *I-bit* is one and the *Active* bit is zero, the host controller immediately skips processing of this queue head, exits this state and uses the horizontal pointer to the next schedule data structure. If the field *Bytes to Transfer* is not zero and the *T-bit* in the *Alternate Next qTD Pointer* is set to zero, then the host controller uses the *Alternate Next qTD Pointer*. Otherwise, the host controller uses the *NextqTD Pointer*. If *NextqTD Pointer's T-bit* is set to one, then the host controller exits this state and uses the horizontal pointer to the next schedule data structure.

Using the selected pointer the host controller fetches the referenced qTD. If the fetched qTD has its *Active* bit set to one, the host controller moves the pointer value used to reach the qTD (*Next* or *Alternate Next*) to the *Current qTD Pointer* field, then performs the overlay. If the fetched qTD has its *Active* bit set to zero, the host controller aborts the queue advance and follows the queue head's horizontal pointer to the next schedule data structure.

The host controller performs the overlay based on the following rules:

- The value of the data toggle (*dt*) field in the overlay area depends on the value of the *data toggle control (dtc)* bit (see [Table 41-28](#)).
- If the *EPS* field indicates the endpoint is a high-speed endpoint, the *Ping* state field is preserved by the host controller. The value of this field is not changed as a result of the overlay.
- *C-prog-mask* field is set to zero (field from incoming qTD is ignored, as is the current contents of the overlay area).
- *Frame Tag* field is set to zero (field from incoming qTD is ignored, as is the current contents of the overlay area).
- *NakCnt* field in the overlay area is loaded from the *RL* field in the queue head's Static Endpoint State.
- All other areas of the overlay are set by the incoming qTD.

The host controller exits this state when it has committed the write to the queue head.

### 41.5.3.10.3 Execute Transaction

The host controller enters this state from the Fetch Queue Head state only if the *Active* bit in *Status* field of the queue head is set to one.

On entry to this state, the host controller executes a few pre-operations, then checks some pre-condition criteria before committing to executing a transaction for the queue head.

The pre-operations performed and the pre-condition criteria depend on whether the queue head is an interrupt endpoint. The host controller can determine that a queue head is an interrupt queue head when the queue head's *S-mask* field contains a non-zero value. It is the responsibility of software to ensure the *S-mask* field is appropriately initialized based on the transfer type. There are other criteria that must be met if the *EPS* field indicates that the endpoint is a low- or full-speed endpoint, see [Split Transactions for Asynchronous Transfers](#) and [Split Transaction Interrupt](#) .

#### 41.5.3.10.3.1 Interrupt Transfer Pre-condition Criteria

If the queue head is for an interrupt endpoint (for example, non-zero *S-mask* field), then the FRINDEX[2:0] field must identify a bit in the *S-mask* field that has one in it.

For example, an *S-mask* value of 00100000b would evaluate to true only when FRINDEX[2:0] is equal to 101b. If this condition is met then the host controller considers this queue head for a transaction.

#### 41.5.3.10.3.2 Asynchronous Transfer Pre-operations and Pre-condition Criteria

If the queue head is not for an interrupt endpoint (for example, zero *S-mask* field), then the host controller performs one pre-operation and then evaluates one pre-condition criteria.

The pre-operation is:

Checks the Nak counter reload state ([Operational Model for Nak Counter](#)). It may be necessary for the host controller to reload the Nak Counter field. The reload is performed at this time.

The pre-condition evaluated is:

- Whether or not the *NakCnt* field has been reloaded, the host controller checks the value of the *NakCnt* field in the queue head. If *NakCnt* is non-zero, or if the *Reload Nak Counter* field is zero, then the host controller considers this queue head for a transaction.

### 41.5.3.10.3.3 Transfer Type Independent Pre-operations

Regardless of the transfer type, the host controller always performs at least one pre-operation and evaluates one pre-condition. The pre-operation is:

- A host controller internal transaction (down) counter *qHTransactionCounter* is loaded from the queue head's *Mult* field. A host controller implementation is allowed to ignore this for queue heads on the asynchronous list. It is mandatory for interrupt queue heads. Software should ensure that the *Mult* field is set appropriately for the transfer type.

The pre-conditions evaluated are:

- The host controller determines whether there is enough time in the micro-frame to complete this transaction (see [Transaction Fit - A Best-Fit Approximation Algorithm](#) for an example evaluation method). If there is not enough time to complete the transaction, the host controller exits this state.
- If the value of *qHTransactionCounter* for an interrupt endpoint is zero, then the host controller exits this state.

When the pre-operations are complete and pre-conditions are met, the host controller sets the *Reclamation* bit in the USBSTS register to one and then begins executing one or more transactions using the endpoint information in the queue head. The host controller iterates *qHTransactionCounter* times in this state executing transactions. After each transaction is executed, *qHTransactionCounter* is decremented by one. The host controller exits this state when one of the following events occurs:

- The *qHTransactionCounter* decrements to zero, or
- The endpoint responds to the transaction with any handshake other than an ACK,<sup>4</sup> or
- The transaction experiences a transaction error, or
- The *Active* bit in the queue head goes to zero, or
- There is not enough time in the micro-frame left to execute the next transaction(see [Transaction Fit - A Best-Fit Approximation Algorithm](#) ) for example method for implementing the frame boundary test).

#### NOTE

For a high-bandwidth interrupt OUT endpoint, the host controller may optionally immediately retry the transaction if it fails.

The results of each transaction is recorded in the on-chip overlay area. If data was successfully moved during the transaction, the transfer state in the overlay area is advanced. To advance queue head's transfer state, the *Total Bytes to Transfer* field is decremented by the number of bytes moved in the transaction, the data toggle bit (*dt*) is toggled, the current page offset is advanced to the next appropriate value (for example,

advanced by the number of bytes successfully moved), and the *C\_Page* field is updated to the appropriate value (if necessary). See [Buffer Pointer List Use for Data Streaming with qTDs](#) .

### NOTE

The *Total Bytes To Transfer* field may be zero when all the other criteria for executing a transaction are met. When this occurs, the host controller executes zero-length transaction to the endpoint. If the *PID\_Code* field indicates an IN transaction and the device delivers data, the host controller detects a packet babble condition, set the *babble* and *halted* bits in the *Status* field, set the *Active* bit to zero, write back the results to the source qTD, then exit this state.

In the event an IN token receives a data PID mismatch response, the host controller must ignore the received data (for example not advance the transfer state for the bytes received). Additionally, if the endpoint is an interrupt IN, then the host controller must record that the transaction occurred (for example, decrement *qHTransactionCounter*). It is recommended (but not required) the host controller continue executing transactions for this endpoint if the resultant value of *qHTransactionCounter* is greater than one.

If the response to the IN bus transaction is a Nak (or Nyet) and *RL* is non-zero, *NakCnt* is decremented by one. If *RL* is zero, then no write-back by the host controller is required (for a transaction receiving a Nak or Nyet response and the value of *CErr* did not change). Software should set the *RL* field to zero if the queue head is an interrupt endpoint. Host controller hardware is not required to enforce this rule or operation.

After the transaction has finished and the host controller has completed the post processing of the results (advancing the transfer state and possibly *NakCnt*, the host controller writes back the results of the transaction to the queue head's overlay area in main memory).

The number of bytes moved during an IN transaction depends on how much data the device endpoint delivers. The maximum number of bytes a device can send is *MaximumPacket Size*. The number of bytes moved during an OUT transaction is either *Maximum Packet Length* bytes or *Total Bytes to Transfer*, whichever is less.

If there was a transaction error during the transaction, the transfer state (as defined above) is not advanced by the host controller. The *CErr* field is decremented by one and the status field is updated to reflect the type of error observed. Transaction errors are summarized in [Transaction Error](#) .

The following events causes the host controller to clear the *Active* bit in the queue head's overlay status field. When the *Active* bit transitions from one to zero, the transfer in the overlay is considered complete. The reason for the transfer completion (clearing the *Active* bit) determines the next state.

- *CErr* field decrements to zero. When this occurs the *Halted* bit is set to one and *Active* is set to zero. This results in the hardware not advancing the queue and the pipe halts. Software must intercede to recover.
- The device responds to the transaction with a STALL PID. When this occurs, the *Halted* bit is set to one and the *Active* bit is set to zero. This results in the hardware not advancing the queue and the pipe halts. Software must intercede to recover.
- The *Total Bytes to Transfer* field is zero after the transaction completes.
  - For a zero length transaction, it was zero before the transaction was started. When this condition occurs, the *Active* bit is set to zero.
- The PID code is an IN, and the number of bytes moved during the transaction is less than the *Maximum Packet Length*. When this occurs, the *Active* bit is set to zero and a short packet condition exists. The short-packet condition is detected during the Advance Queue state. Refer to [Split Transactions](#) for additional rules for managing low- and full-speed transactions.

With the exception of a NAK response (when *RL* field is zero), the host controller always writes the results of the transaction back to the overlay area in main memory. This includes when the transfer completes. For a high-speed endpoint, the queue head information written back includes minimally the following fields: The *PID Code* field indicates an IN and the device sends more than the expected number of bytes (for example *Maximum Packet Length* or *Total Bytes to Transfer* bytes, whichever is less) (for example a packet babble). This results in the host controller setting the *Halted* bit to one.

- NakCnt, dt, Total Bytes to Transfer, C\_Page, Status, CERR, and Current Offset

For a low- or full-speed device the queue head information written back also includes the fields:

- C-prog-mask, FrameTag and S-bytes.

The duration of this state depends on the time it takes to complete the transaction(s) and the status write to the overlay is committed.

#### 41.5.3.10.3.4 Halting a Queue Head

A halted endpoint is defined only for the transfer types that are managed through queue heads (control, bulk and interrupt).

The following events indicate that the endpoint has reached a condition where no more activity can occur without intervention from the driver:

- An endpoint may return a STALL handshake during a transaction,
- A transaction had three consecutive error conditions, or
- A Packet Babble error occurs on the endpoint.

When any of these events occur (for a queue head) the Host Controller halts the queue head and set the USBERRINT status bit in the USB\_n\_USBSTS register to one. To halt the queue head, the *Active* bit is set to zero and the *Halted* bit is set to one. There may be other error status bits that are set when a queue is halted. The host controller always writes back the overlay area to the source qTD when the transfer is complete, regardless of the reason (normal completion, short packet or halt). The host controller does not advance the transfer state on a transaction that results in a *Halt* condition (for example no updates necessary for *Total Bytes to Transfer*, *C\_Page*, *Current Offset*, and *dt*). The host controller must update *CErr* as appropriate. When a queue head is halted, the *USB Error Interrupt* bit in the USB\_n\_USBSTS register is set to one. If the *USB Error Interrupt Enable* bit in the USB\_n\_USBINTR register is set to one, a hardware interrupt is generated at the next interrupt threshold.

#### 41.5.3.10.3.5 Asynchronous Schedule Park Mode

Asynchronous Schedule Park mode is a special execution mode that can be enabled by system software, where the host controller is permitted to execute more than one bus transaction from a high-speed queue head in the Asynchronous schedule before continuing horizontal traversal of the Asynchronous schedule.

This feature has no effect on queue heads or other data structures in the Periodic schedule. This feature is similar in intent as the *Mult* feature that is used in the Periodic schedule. Where-as the *Mult* feature is a characteristic that is tunable for each endpoint; park-mode is a policy that is applied to all high-speed queue heads in the asynchronous schedule. It is essentially the specification of an iterator for consecutive bus transactions to the same endpoint. All of the rules for managing bus transactions and the results of those as defined in [Execute Transaction](#) apply. This feature merely specifies how many consecutive times the host controller is permitted to execute from the same queue head before moving to the next queue head in the Asynchronous List. This feature should allow the host controller to attain better bus utilization for those devices that are capable of moving data at maximum rate, while at the same time providing a fair service to all endpoints.

A host controller exports its capability to support this feature to system software by setting the *Asynchronous Schedule Park Capability* bit in the USB\_n\_HCCPARAMs register to one. This information keys system software that the *Asynchronous Schedule Park Mode Enable* and *Asynchronous Schedule Park Mode Count* fields in the USB\_n\_USBCMD register are modifiable. System software enables the feature by writing a one to the *Asynchronous Schedule Park Mode Enable* bit.

When park-mode is not enabled (for example *Asynchronous Schedule Park Mode Enable* bit in the USB\_n\_USBCMD register is zero), the host controller must not execute more than one bus transaction per high-speed queue head, per traversal of the asynchronous schedule. When park-mode is enabled, the host controller must not apply the feature to a queue head whose *EPS* field indicates a Low/Full-speed device (for example only one bus transaction is allowed from each Low/Full-speed queue head per traversal of the asynchronous schedule). Park-mode may only be applied to queue heads in the Asynchronous schedule whose *EPS* field indicates that it is a high-speed device.

The host controller must apply park mode to queue heads whose *EPS* field indicates a high-speed endpoint. The maximum number of consecutive bus transactions a host controller may execute on a high-speed queue head is determined by the value in the *Asynchronous Schedule Park Mode Count* field in the USB\_n\_USBCMD register. Software must not set *Asynchronous Schedule Park Mode Enable* bit to one and also set *Asynchronous Schedule Park Mode Count* field to zero. The resulting behavior is not defined. An example behavioral example describes the operational requirements for the host controller implementing park-mode. This feature does not affect how the host controller handles the bus transaction as defined in [Execute Transaction](#) . It only effects how many consecutive bus transactions for the current queue head can be executed. All boundary conditions, error detection and reporting applies as usual. This feature is similar in concept to the use of the *Mult* field for high-bandwidth Interrupt for queue heads in the Periodic Schedule.

The host controller effectively loads an internal down-counter *PM-Count* from *Asynchronous Schedule Park Mode Count* when *Asynchronous Schedule Park Mode Enable* bit is one, and a high-speed queue head is first fetched and meets all the criteria for executing a bus transaction. After the bus transaction, *PM-Count* is decremented. The host controller may continue to execute bus transactions from the current queue head until *PM-Count* goes to zero, an error is detected, the buffer for the current transfer is exhausted or the endpoint responds with a flow-control or STALL handshake.

The following table summarizes the responses that effect whether the host controller continues with another bus transaction for the current queue head.

**Table 41-44. Actions for Park Mode, based on Endpoint Response and Residual Transfer State**

PID	Endpoint Response	Transfer State after Transaction		Action
		PM-Count	Bytes to Transfer	
IN	DATA[0,1] w/Maximum Packet sized data	Not zero	Not Zero	Allowed to perform another bus transaction. <sup>1, 2</sup>
		Not zero	Zero	Retire qTD and move to next QH
		Zero	Don't care	Move to next QH.

*Table continues on the next page...*

**Table 41-44. Actions for Park Mode, based on Endpoint Response and Residual Transfer State (continued)**

	DATA[0,1] w/short packet	Don't care	Don't care	Retire qTD and move to next QH.
	NAK	Don't care	Don't care	Move to next QH.
	STALL, XactErr	Don't care	Don't care	Move to next QH.
OUT	ACK	Not zero	Not Zero	Allowed to perform another bus transaction. <sup>2</sup>
		Not zero	Zero	Retire qTD and move to next QH
		Zero	Don't care	Move to next QH.
	NYET, NAK	Don't care	Don't care	Move to next QH.
	STALL, XactErr	Don't care	Don't care	Move to next QH
PING	ACK	Not Zero	Not Zero	Allowed to perform another bus transaction. <sup>2</sup>
	NAK	Don't care	Don't care	Move to next QH
	STALL, XactErr	Don't care	Don't care	Move to next QH

1. The host controller may continue to execute bus transactions from the current high-speed queue head (if *PM-Count* is not equal to zero), if a PID mismatch is detected (for example expected DATA1 and received DATA0, or visa-versa).
2. This specification does not *require* that the host controller execute another bus transaction when *PM-Count* is non-zero. Implementations are encouraged to make appropriate complexity and performance trade-offs.

#### 41.5.3.10.4 Write Back qTD

This state is entered from the Execute Transaction state when the *Active* bit is set to zero.

The source data for the write-back is the transfer results area of the queue head overlay area (see [Table 41-44](#)).

The host controller uses the *Current qTD Pointer* field as the target address for the qTD.

The queue head transfer result area is written back to the transfer result area of the target qTD. This state is also referred to as: qTD retirement. The fields that must be written back to the source qTD include *Total Bytes to Transfer*, *Cerr*, and *Status*.

The duration of this state depends on when the qTD write-back is committed.

#### 41.5.3.10.5 Follow Queue Head Horizontal Pointer

The host controller must use the horizontal pointer in the queue head to the next schedule data structure when any of the following conditions exist:

- If the *Active* bit is one on exit from the Execute Transaction state, or
- When the host controller exits the Write Back qTD state, or
- If the Advance Queue state fails to advance the queue because the target qTD is not active, or
- If the *Halted* bit is one on exit from the Fetch QH state.

There is no functional requirement that the host controller wait until the current transaction is complete before using the horizontal pointer to read the next linked data structure. However, it must wait until the current transaction is complete before executing the next data structure.

#### 41.5.3.10.6 Buffer Pointer List Use for Data Streaming with qTDs

A qTD has an array of buffer pointers, which is used to reference the data buffer for a transfer. This specification requires that the buffer associated with the transfer be *virtually contiguous*.

This means: if the buffer spans more than one physical page, it must obey the following rules (the figure below illustrates an example):

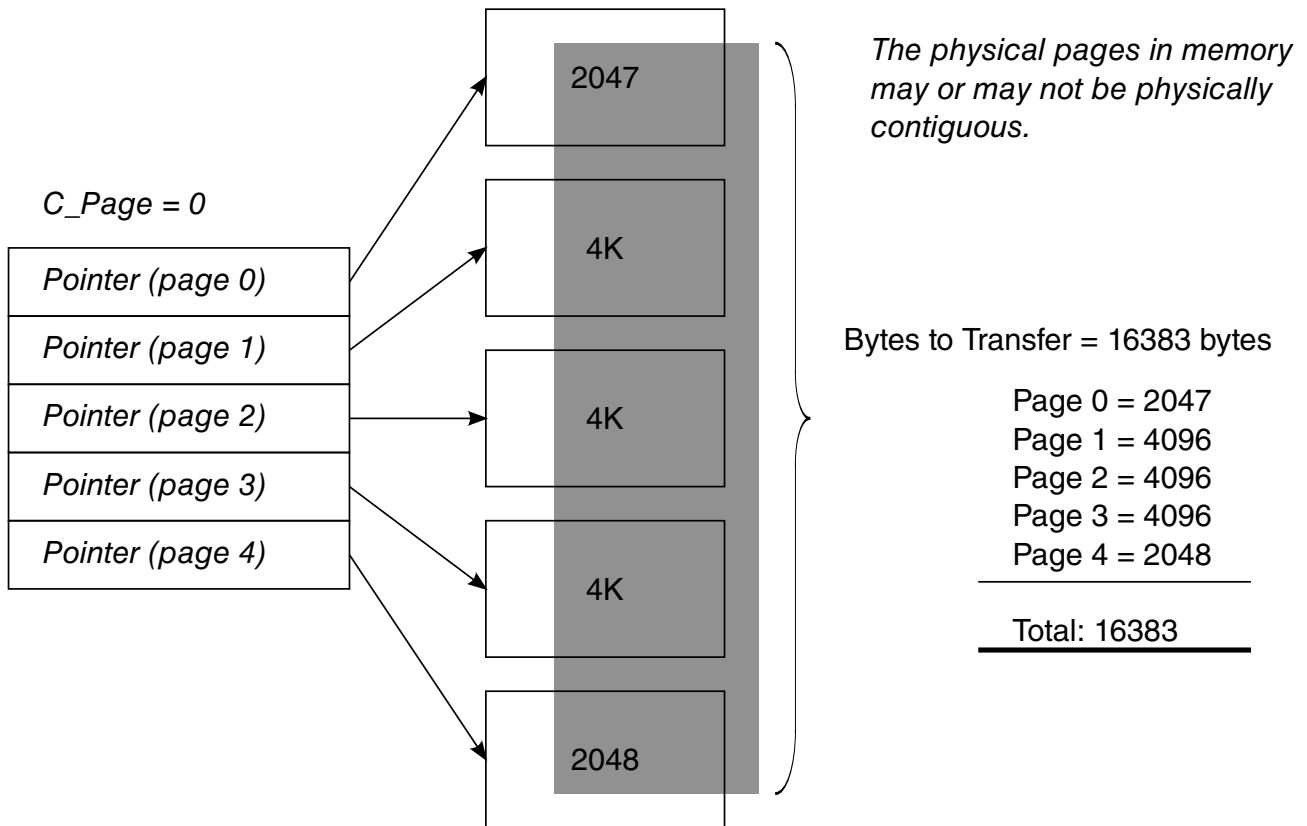

- The first portion of the buffer must begin at some offset in a page and extend through the end of the page.
- The remaining buffer cannot be allocated in small chunks scattered around memory. For each 4 K chunk beyond the first page, each buffer portion matches to a full 4 K page. The final portion, which may only be large enough to occupy a portion of a page, must start at the top of the page and be contiguous within that page.

The buffer pointer list in the qTD is long enough to support a maximum transfer size of 20 K bytes. This case occurs when all five buffer pointers are used and the first offset is zero. A qTD handles a 16 Kbyte buffer with any starting buffer alignment.

The host controller uses the field *C\_Page* field as an index value to determine which buffer pointer in the list should be used to start the current transaction. The host controller uses a different buffer pointer for each physical page of the buffer. This is always true, even if the buffer is physically contiguous.

The host controller must detect when the current transaction spans a page boundary and automatically move to the next available buffer pointer in the page pointer list. The next available pointer is reached by incrementing *C\_Page* and pulling the next page pointer from the list. Software must ensure there are sufficient buffer pointers to move the amount of data specified in the *Bytes to Transfer* field.

The following figure illustrates a nominal example of how System software would initialize the buffer pointers list and the *C\_Page* field for a transfer size of 16383 bytes. *C\_Page* is set to zero. The upper 20-bits of Page 0 references the start of the physical page. *Current Offset* (the lower 12-bits of queue head Dword 7) holds the offset in the page for example 2049 (for example 4096-2047). The remaining page pointers are set to reference the beginning of each subsequent 4 K page.

**Figure 41-18. Example Mapping of qTD Buffer Pointers to Buffer Pages**

For the first transaction on the qTD (assuming a 512-byte transaction), the host controller uses the first buffer pointer (page 0 because *C\_Page* is set to zero) and concatenates the *Current Offset* field. The 512 bytes are moved during the transaction, the *Current Offset* and *Total Bytes to Transfer* are adjusted by 512 and written back to the queue head working area.

During the 4<sup>th</sup> transaction, the host controller needs 511 bytes in page 0 and one byte in page 1. The host controller increments *C\_Page* (to 1) and use the page 1 pointer to move the final byte of the transaction. After the 4<sup>th</sup> transaction, the active page pointer is the page 1 pointer and *Current Offset* has rolled to one, and both are written back to the overlay area. The transactions continue for the rest of the buffer, with the host controller automatically moving to the next page pointer (that is *C\_Page*) when necessary. The three conditions for how the host controller handles *C\_Page*:

- The current transaction does not span a page boundary. The value of *C\_Page* is not adjusted by the host controller.

- The current transaction does span a page boundary. The host controller must detect the page cross condition and advance to the next buffer while streaming data to/from the USB.
- The current transaction completes on a page boundary (that is the last byte moved for the current transaction is the last byte in the page for the current page pointer). The host controller must increment *C\_Page* before writing back status for the transaction.

### NOTE

The only valid adjustment the host controller may make to *C\_Page* is to increment by one.

#### 41.5.3.10.7 Adding Interrupt Queue Heads to the Periodic Schedule

The link path(s) from the periodic frame list to a queue head establishes in which frames a transaction can be executed for the queue head. Queue heads are linked into the periodic schedule so they are polled at the appropriate rate.

System software sets a bit in a queue head's *S-Mask* to indicate which micro-frame within 1 msec period a transaction should be executed for the queue head. Software must ensure that all queue heads in the periodic schedule have *S-Mask* set to a non-zero value. An *S-mask* with zero value in the context of the periodic schedule yields undefined results.

If the desired poll rate is greater than one frame, system software can use a combination of queue head linking and *S-Mask* values to spread interrupts of equal poll rates through the schedule so that the periodic bandwidth is allocated and managed in the most efficient manner possible. Some examples are illustrated in the following table.

**Table 41-45. Example Periodic Reference Patterns for Interrupt Transfers with 2ms Poll Rate**

Frame # Reference Sequence	Description
0, 2, 4, 6, 8, and so on <i>S-Mask</i> = 01h	A queue head for the <i>bInterval</i> of 2 msec (16 micro-frames) is linked into the periodic schedule so that it is reachable from the periodic frame list locations indicated in the previous column. In addition, the <i>S-Mask</i> field in the queue head is set to 01h, indicating that the transaction for the endpoint should be executed on the bus during micro-frame 0 of the frame.
0, 2, 4, 6, 8, and so on <i>S-Mask</i> = 02h	Another example of a queue head with a <i>bInterval</i> of 2 msec is linked into the periodic frame list at exactly the same interval as the previous example. However, the <i>S-Mask</i> is set to 02h indicating that the transaction for the endpoint should be executed on the bus during micro-frame 1 of the frame.

### 41.5.3.10.8 Managing Transfer Complete Interrupts from Queue Heads

The host controller sets an interrupt to be signaled at the next interrupt threshold when the completed transfer (qTD) has an *Interrupt on Complete (IOC)* bit set to one, or whenever a transfer (qTD) completes with a short packet.

If system software needs multiple qTDs to complete a client request (that is like a control transfer) the intermediate qTDs do not require interrupts. System software may only need a single interrupt to notify it that the complete buffer has been transferred. System software may set IOC's to occur more frequently. A motivation for this may be that it wants early notification so that interface data structures can be re-used in a timely manner.

### 41.5.3.11 Ping Control

USB 2.0 defines an addition to the protocol for high-speed devices called Ping. Ping is required for all USB 2.0 High-speed bulk and control endpoints.

Ping is not allowed for a split-transaction stream. This extension to the protocol eliminates the bad side-effects of Naking OUT endpoints. The *Status* field has a *Ping State* bit, which the host controller uses to determine the *next* actual PID it uses in the next transaction to the endpoint (see the table below).

The Ping State bit is only managed by the host controller for queue heads that meet the following criteria:

- Queue head is not an interrupt and
- *EPS* field equals High-Speed and
- *PIDCode* field equals OUT

The following table illustrates the state transition table for the host controller's responsibility for maintaining the PING protocol. Refer to Chapter 8 in the USB Specification Revision 2.0 for detailed description on the Ping protocol.

**Table 41-46. Ping Control State Transition Table**

Event	Host	Device	Next
Current	Host	Device	Next
Do Ping	PING	Nak	Do Ping
Do Ping	PING	Ack	Do OUT
Do Ping	PING	XactErr <sup>1</sup>	Do Ping
Do Ping	PING	Stall	N/C <sup>2</sup> Do
OUT	OUT	Nak	Do Ping
Do OUT	OUT	Nyet	Do Ping

*Table continues on the next page...*

**Table 41-46. Ping Control State Transition Table (continued)**

Do OUT	OUT	Ack	Do OUT
Do OUT	OUT	XactErr <sup>1</sup>	Do Ping
Do OUT	OUT	Stall	N/C <sup>2</sup>

1. Transaction Error (XactErr) is any time the host misses the handshake.
2. No transition change required for the Ping State bit. The Stall handshake results in the endpoint being halted (for example Active set to zero and Halt set to one). Software intervention is required to restart queue. 3 A Nyet response to an OUT means that the device has accepted the data, but cannot receive any more at this time. Host must advance the transfer state and additionally, transition the Ping State bit to Do Ping. The Ping State bit has the following encoding:

**Table 41-47. Ping State bit Encoding**

Value	Meaning
0B	Do OUT The host controller uses an OUT PID during the next bus transaction to this endpoint.
1B	Do Ping The host controller uses a PING PID during the next bus transaction to this endpoint.

The defined ping protocol (see USB 2.0 Specification, Chapter 8) allows the host to be *imprecise* on the initialization of the ping protocol (that is start in *Do OUT* when we don't know whether there is space on the device or not). The host controller manages the *Ping State* bit. System software sets the initial value in the queue head when it initializes a queue head. The host controller preserves the *Ping State* bit across all queue advancements. This means that when a new qTD is written into the queue head overlay area, the previous value of the *Ping State* bit is preserved.

### 41.5.3.12 Split Transactions

USB 2.0 defines extensions to the bus protocol for managing USB 1.x data streams through USB 2.0 Hubs.

This section describes how the host controller uses the interface data structures to manage data streams with full- and low-speed devices, connected below USB 2.0 hub, utilizing the split transaction protocol.

Refer to USB 2.0 Specification for the complete definition of the split transaction protocol. Full- and Low-speed devices are enumerated identically as high-speed devices, but the transactions to the Full- and Low-speed endpoints use the split-transaction protocol on the high-speed bus. The split transaction protocol is an encapsulation of (or wrapper around) the Full- or Low-speed transaction. The high-speed wrapper portion of the protocol is addressed to the USB 2.0 Hub and Transaction Translator below which the Full- or Low-speed device is attached.

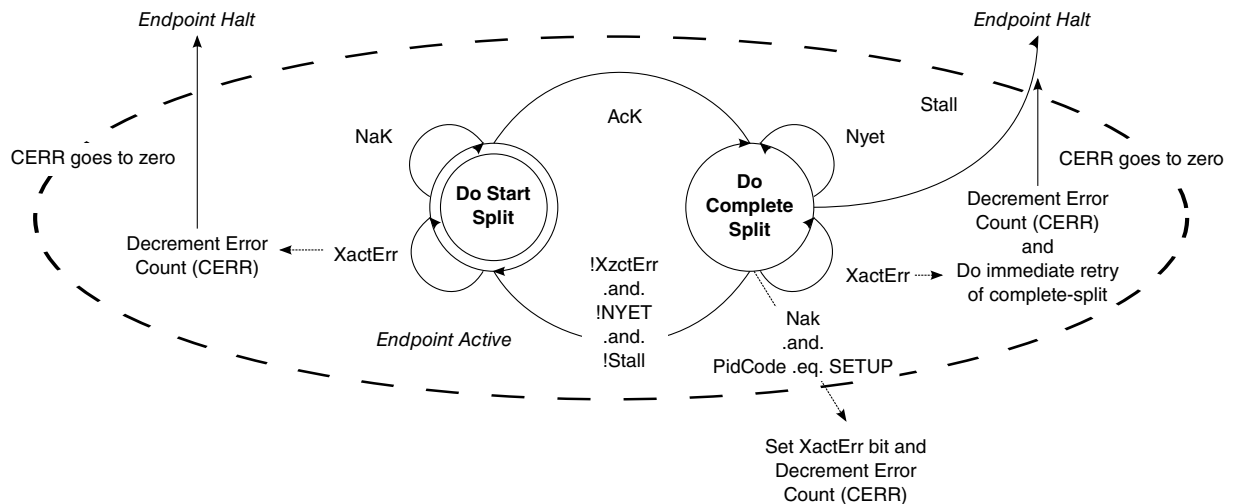

The EHCI interface uses dedicated data structures for managing full-speed isochronous data streams (see [Split Transaction Isochronous Transfer Descriptor \(siTD\)](#)). Control, Bulk and Interrupt are managed using the queuing data structures (see [Queue Head](#)). The interface data structures need to be programmed with the device address and the Transaction Translator number of the USB 2.0 Hub operating as the Low-/Full-speed host controller for this link. The following sections describe the details of how the host controller must process and manage the split transaction protocol.

### 41.5.3.12.1 Split Transactions for Asynchronous Transfers

A queue head in the asynchronous schedule with an *EPS* field indicating a full-or low-speed device indicates to the host controller that it must use split transactions to stream data for this queue head.

All full-speed bulk and full-, low-speed control are managed through queue heads in the asynchronous schedule.

Software must initialize the queue head with the appropriate device address and port number for the transaction translator that is serving as the full/low-speed host controller for the links connecting the endpoint. Software must also initialize the split transaction state bit (*SplitXState*) to Do-Start-Split. Finally, if the endpoint is a control endpoint, then system software must set the *Control Transfer Type (C)* bit in the queue head to one. If this is not a control transfer type endpoint, the *C* bit must be initialized by software to be zero. This information is used by the host controller to properly set the Endpoint Type (ET) field in the split transaction bus token. When the *C* bit is zero, the split transaction token's ET field is set to indicate a bulk endpoint. When the *C* bit is one, the split transaction token's ET field is set to indicate a control endpoint. Refer to Chapter 8 of USB Specification Revision 2.0 for details.

**Figure 41-19. Host Controller Asynchronous Schedule Split-Transaction State Machine**

#### 41.5.3.12.1.1 Asynchronous - Do Start Split

This is the state which software must initialize a full- or low-speed asynchronous queue head. This state is entered from the Do Complete Split state only after a complete-split transaction receives a valid response from the transaction translator that is not a Nyet handshake.

For queue heads in this state, the host controller executes a start-split transaction to the appropriate transaction translator. If the bus transaction completes without an error and *PidCode* indicates an IN or OUT transaction, then the host controller reloads the error counter (*CErr*). If it is a successful bus transaction and the *PidCode* indicates a SETUP, the host controller does not reload the error counter. If the transaction translator responds with a Nak, the queue head is left in this state, and the host controller proceeds to the next queue head in the asynchronous schedule.

If the host controller times out the transaction (no response, or bad response) the host controller decrements *Cerr* and proceeds to the next queue head in the asynchronous schedule.

#### 41.5.3.12.1.2 Asynchronous - Do Complete Split

This state is entered from the Do Start Split state only after a start-split transaction receives an Ack handshake from the transaction translator.

For queue heads in this state, the host controller executes a complete-split transaction to the appropriate transaction translator. If the transaction translator responds with a Nyet handshake, the queue head is left in this state, the error counter is reset and the host controller proceeds to the next queue head in the asynchronous schedule. When a Nyet handshake is received for a bus transaction where the queue head's *PidCode* indicates an IN or OUT, the host controller reloads the error counter (*CErr*). When a Nyet handshake is received for a complete-split bus transaction where the queue head's *PidCode* indicates a SETUP, the host controller must not adjust the value of *CErr*.

Independent of *PIDCode*, the following responses have the effects:

- Transaction Error (XactErr). Timeout or data CRC failure, and so on. The error counter (*Cerr*) is decremented by one and the complete split transaction is *immediately* retried (if possible). If there is not enough time in the micro-frame to execute the retry, the host controller **MUST** ensure that the next time the host controller begins executing from the Asynchronous schedule, it must begin executing from this queue head. If another start-split (for some other endpoint) is sent to the transaction translator before the complete-split is really completed, the transaction translator could dump the results (which were never delivered to the host). This is why the core specification states the retries must be immediate. A method to

accomplish this behavior is to not advance the asynchronous schedule. When the host controller returns to the asynchronous schedule in the next micro-frame, the first transaction from the schedule is the retry for this endpoint.

If *Cerr* went to zero, the host controller must halt the queue.

- **NAK.** The target endpoint Nak'd the full- or low-speed transaction. The state of the transfer is not advanced and the state is exited. If the *PidCode* is a SETUP, then the Nak response is a protocol error. The *XactErr* status bit is set to one and the *CErr* field is decremented.
- **STALL.** The target endpoint responded with a STALL handshake. The host controller sets the *halt* bit in the status byte, retires the qTD but does not attempt to advance the queue.

If the *PidCode* indicates an IN, then any of following responses are expected:

- **DATA0/1.** On reception of data, the host controller ensures the PID matches the expected data toggle and checks CRC. If the packet is *good*, the host controller advances the state of the transfer, for example move the data pointer by the number of bytes received, decrement *BytesToTransfer* field by the number of bytes received, and toggle the *dt* bit. The host controller then exit this state. The response and advancement of transfer may trigger other processing events, such as retirement of the qTD and advancement of the queue.

If the data sequence PID does not match the expected, the data is ignored, the transfer state is not advanced and this state is exited. If the *PidCode* indicates an OUT/SETUP, then any of following responses are expected:

- **ACK.** The target endpoint accepted the data, so the host controller must advance the state of the transfer. The *Current Offset* field is incremented by *Maximum Packet Length* or *Bytes to Transfer*, whichever is less. The field *Bytes To Transfer* is decremented by the same amount and the data toggle bit (*dt*) is toggled. The host controller then exit this state.
- Advancing the transfer state may cause other processing events such as retirement of the qTD and advancement of the queue (see [Managing Control/Bulk/Interrupt Transfers through Queue Heads](#)).

#### 41.5.3.12.2 Split Transaction Interrupt

Split-transaction Interrupt-IN/OUT endpoints are managed through the same data structures used for high-speed interrupt endpoints. They both co-exist in the periodic schedule.

Queue heads/qTDs offer the set of features required for reliable data delivery, which is characteristic to interrupt transfer types. The split-transaction protocol is managed completely within this defined functional transfer framework. For example, for a high-speed endpoint, the host controller visits a queue head, execute a high-speed transaction (if criteria are met) and advance the transfer state (or not) depending on the results of the entire transaction. For low- and full-speed endpoints, the details of the *execution* phase are different (that is takes more than one bus transaction to complete), but the remainder of the operational framework is intact. This means that the transfer advancement, and so on, occurs as defined in [Managing Control/Bulk/Interrupt Transfers through Queue Heads](#), but only occurs on the completion of a split transaction.

#### 41.5.3.12.2.1 Split Transaction Scheduling Mechanisms for Interrupt

Full- and low-speed Interrupt queue heads have an *EPS* field indicating full- or low-speed and have a non-zero *S-mask* field.

The host controller can detect this combination of parameters and assume the endpoint is a periodic endpoint. Low- and full-speed interrupt queue heads require the use of the split transaction protocol. The host controller sets the Endpoint Type (ET) field in the split token to indicate the transaction is an interrupt. These transactions are managed through a transaction translator's periodic pipeline. Software should not set these fields to indicate the queue head is an interrupt unless the queue head is used in the periodic schedule.

System software manages the per/transaction translator periodic pipeline by budgeting and scheduling exactly during which micro-frames the start-splits and complete-splits for each endpoint occurs. The characteristics of the transaction translator are such that the high-speed transaction protocol must execute during explicit micro-frames, or the data or response information in the pipeline is lost.

The following figure illustrates the general scheduling boundary conditions that are supported by the EHCI periodic schedule and queue head data structure. The S and <sup>C</sup>X labels indicate micro-frames where software can schedule start-splits and complete splits (respectively).

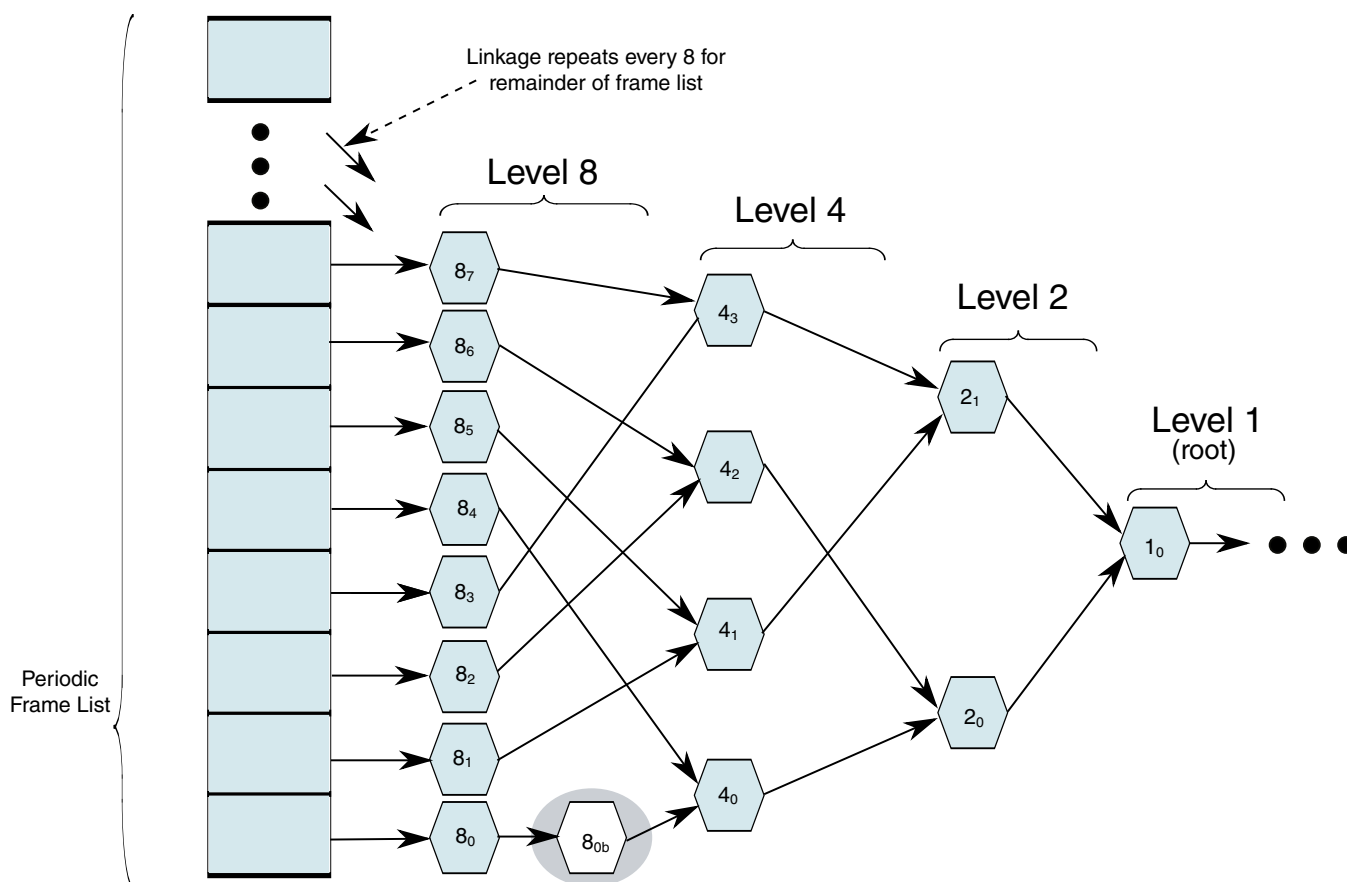

**Figure 41-20. Split Transaction, Interrupt Scheduling Boundary Conditions**

The scheduling cases are:

- Case 1: The normal scheduling case is where the entire split transaction is completely bounded by a frame (*H-Frame* in this case).
- Case 2a through Case 2c: The USB 2.0 Hub pipeline rules states clearly, when and how many complete-splits must be scheduled to account for earliest to latest execution on the full/low-speed link. The complete-splits may span the *H-Frame* boundary when the start-split is in micro-frame 4 or later. When this occurs, the *H-Frame* to *B-Frame* alignment requires that the queue head be reachable from consecutive periodic frame list locations. System software cannot build an efficient schedule that satisfies this requirement unless it uses FSTNs.

The figure below illustrates the general layout of the periodic schedule.

**Figure 41-21. General Structure of EHCI Periodic Schedule Utilizing Interrupt Spreading**

The periodic frame list is effectively the leaf level a binary tree, which is always traversed leaf to root. Each level in the tree corresponds to a  $2^N$  poll rate. Software can efficiently manage periodic bandwidth on the USB by *spreading* interrupt queue heads that have the same poll rate requirement across all the available paths from the frame list. For example, system software can schedule eight poll rate 8 queue heads and account for them once in the high-speed bus bandwidth allocation.

When an endpoint is allocated an execution footprint that spans a frame boundary, the queue head for the endpoint must be reachable from consecutive locations in the frame list. An example would be if 8<sub>0b</sub> where such an endpoint. Without additional support on the interface, to get 8<sub>0b</sub> reachable at the correct time, software would have to link 8<sub>1</sub> to 8<sub>0b</sub>. It would then have to move 4<sub>1</sub> and everything linked after into the same path as 4<sub>0</sub>. This upsets the integrity of the binary tree and disallows the use of the spreading technique.

FSTN data structures are used to preserve the integrity of the binary-tree structure and enable the use of the spreading technique. [Host Controller Operational Model for FSTNs](#) defines the hardware and software operational model requirements for using FSTNs.

The following queue head fields are initialized by system software to instruct the host controller when to execute portions of the split-transaction protocol:

- *SplitXState*. This is single bit residing in the *Status* field of a queue head (see [Table 41-24](#)). This bit is used to track the current state of the split transaction.
- *Frame S-mask*. This is a bit-field where-in system software sets a bit corresponding to the micro-frame (within an *H-Frame*) that the host controller should execute a start-split transaction. This is always qualified by the value of the *SplitXState* bit in the *Status* field of the queue head. For example, referring to [Figure 41-20](#), case one, the *S-mask* would have a value of 00000001b indicating that if the queue head is traversed by the host controller, and the *SplitXState* indicates Do\_Start, and the current micro-frame as indicated by FRINDEX[2:0] is 0, then execute a start-split transaction.
- *Frame C-mask*. This is a bit-field where system software sets one or more bits corresponding to the micro-frames (within an *H-Frame*) that the host controller should execute complete-split transactions. The interpretation of this field is always qualified by the value of the *SplitXState* bit in the *Status* field of the queue head. For example, referring to [Figure 41-20](#), case one, the *C-mask* would have a value of 00011100b indicating that if the queue head is traversed by the host controller, and the *SplitXState* indicates Do\_Complete, and the current micro-frame as indicated by FRINDEX[2:0] is 2, 3, or 4, then execute a complete-split transaction. It is software's responsibility to ensure that the translation between *H-Frames* and *B-Frames* is correctly performed when setting bits in *S-mask* and *C-mask*

#### 41.5.3.12.2.2 Host Controller Operational Model for FSTNs

The FSTN data structure is used to manage Low/Full-speed interrupt queue heads that need to be reached from consecutive frame list locations (that is boundary cases 2a through 2c).

An FSTN is essentially a *back pointer*, similar in intent to the back pointer field in the siTD data structure (see [siTD Back Link Pointer](#)).

This feature provides software a simple primitive to save a schedule position, redirect the host controller to traverse the necessary queue heads in the previous frame, then restore the original schedule position and complete normal traversal.

The four components to the use of FSTNs:

- FSTN data structure.
- A *Save Place* indicator. This is always an FSTN with its *Back Path Link Pointer.T-bit* set to zero.

- A *Restore* indicator. This is always an FSTN with its *Back Path Link Pointer.T-bit* set to one.
- Host controller FSTN traversal rules.

When the host controller encounters an FSTN during micro-frames 2 through 7 it simply follows the node's *Normal Path Link Pointer* to access the next schedule data structure.

### NOTE

The FSTN's *Normal Path Link Pointer.T-bit* may set to one, which the host controller must interpret as the end of periodic list mark.

When the host controller encounters a *Save-Place* FSTN in micro-frames 0 or 1, it saves the value of the *Normal Path Link Pointer* and set an internal flag indicating that it is executing in *Recovery Path* mode. *Recovery Path* mode modifies the host controller's rules for how it traverses the schedule and limits which data structures is considered for execution of bus transactions. The host controller continues executing in *Recovery Path* mode until it encounters a *Restore* FSTN or it determines that it has reached the end of the micro-frame (see details in the list below).

The rules for schedule traversal and limited execution while in *Recovery Path* mode are:

- Always follow the *Normal Path Link Pointer* when it encounters an FSTN that is a *Save-Place* indicator. The host controller must not recursively follow *Save-Place* FSTNs. Therefore, while executing in *Recovery Path* mode, it must never follow an FSTN's *Back Path Link Pointer*.
- Do not process an siTD or, iTD data structure. Simply follow its *Next Link Pointer*.
- Do not process a QH (Queue Head) whose *EPS* field indicates a high-speed device. Simply follow its *Horizontal Link Pointer*.
- When a QH's *EPS* field indicates a Full/Low-speed device, the host controller considers only it for execution if its *SplitXState* is DoComplete (note: this applies whether the *PID Code* indicates an IN or an OUT). See [Execute Transaction](#) and [Tracking Split Transaction Progress for Interrupt Transfers](#) for a complete list of additional conditions that must be met in general for the host controller to issue a bus transaction.
  - The host controller must not execute a Start-split transaction while executing in *Recovery Path* mode. See [Periodic Isochronous - Do Complete Split](#) for special handling when in *Recovery Path* mode.
- Stop traversing the *recovery path* when it encounters an FSTN that is a *Restore* indicator. The host controller unconditionally uses the saved value of the *Save-Place* FSTN's *Normal Path Link Pointer* when returning to the normal path traversal. The

host controller must clear the context of executing a *Recovery Path* when it restores schedule traversal to the *Save-Place* FSTN's *Normal Path Link Pointer*.

- If the host controller determines that there is not enough time left in the micro-frame to complete processing of the periodic schedule, it abandons traversal of the recovery path, and clears the context of executing a recovery path. The result is that at the start of the next consecutive micro-frame, the host controller starts traversal at the frame list.

An example traversal of a periodic schedule that includes FSTNs is illustrated in the following figure.

**Figure 41-22. Example Host Controller Traversal of Recovery Path via FSTNs**

In frame N+1 (micro-frames 0 and 1), when the host controller encounters Save-Path FSTN (Save-N), it observes that Save-N.Back Path Link Pointer.T-bit is zero (definition of a Save-Path indicator). The host controller saves the value of Save-N.Normal Path Link Pointer and follows Save-N.Back Path Link Pointer. At the same time, it sets an internal flag indicating that it is now in *Recovery Path* mode (the recovery path is annotated in the figure above with a large dashed line). The host controller continues traversing data structures on the recovery path and executing only those bus transactions as noted above, on the recovery path until it reaches Restore FSTN (Restore-N). Restore-N.Back Path Link Pointer.T-bit is set to one (definition of a Restore indicator), so the host controller exits *Recovery Path* mode by clearing the internal *Recovery Path* mode flag and commences (restores) schedule traversal using the saved value of the *Save-Place* FSTN's *Normal Path Link Pointer* (for example Save-N.Normal Path Link Pointer). The nodes traversed during these micro-frames include: {83,0, 83,1, 83,2, Save-A, 82,2, 82,3, 42,

$2_0$ , Restore-N,  $4_3$ ,  $2_1$ , Restore-N,  $1_0 \dots$ }. The nodes on the recovery-path are in bold. In frame N (micro-frames 0-7), for this example, the host controller traverses all of the schedule data structures utilizing the *Normal Path Link Pointers* in any FSTNs it encounters. This is because the host controller has not yet encountered a *Save-Place* FSTN so it not executing in *Recovery Path* mode. When it encounters the *Restore* FSTN, (Restore-N), during micro-frames 0 and 1, it uses Restore-N.Normal Path Link Pointer to traverse to the next data structure (that is normal schedule traversal). This is because the host controller must use a Restore FSTN's *Normal Path Link Pointer* when not executing in a *Recovery-Path* mode. The nodes traversed during frame N include:  $\{8_{2,0}$ ,  $8_{2,1}$ ,  $8_{2,2}$ ,  $8_{2,3}$ ,  $4_2$ ,  $2_0$ , Restore-N,  $1_0 \dots\}$ .

In frame N+1 (micro-frames 2-7), when the host controller encounters Save-Path FSTN Save-N, it unconditionally follows Save-N.Normal Path Link Pointer. The nodes traversed during these micro-frames include:  $\{8_{3,0}$ ,  $8_{3,1}$ ,  $8_{3,2}$ , Save-A,  $4_3$ ,  $2_1$ , Restore-N,  $1_0 \dots\}$ .

#### 41.5.3.12.2.3 Software Operational Model for FSTNs

Software must create a consistent, coherent schedule for the host controller to traverse.

When using FSTNs, system software must adhere to the following rules:

- Each *Save-Place* indicator requires a matching *Restore* indicator.
  - The *Save-Place* indicator is an FSTN with a valid *Back Path Link Pointer* and *T-bit* equal to zero.
    - *Back Path Link Pointer.Type* field must be set to indicate the referenced data structure is a queue head. The *Restore* indicator is an FSTN with its *Back Path Link Pointer.T-bit* set to one.
  - A *Restore* FSTN may be matched to one or more *Save-Place* FSTNs. For example, if the schedule includes a poll-rate 1 level, then system software only needs to place a *Restore* FSTN at the beginning of this list in order to match all possible *Save-Place* FSTNs.
- If the schedule does not have elements linked at a poll-rate level of one, and one or more *Save-Place* FSTNs are used, then System Software must ensure the *Restore* FSTN's *Normal Path Link Pointer's T-bit* is set to one, as this is used to mark the end of the periodic list.
- When the schedule does have elements linked at a poll rate level of one, a *Restore* FSTN must be the first data structure on the poll rate one list. All traversal paths from the frame list converge on the poll-rate one list. System software must ensure that *Recovery Path* mode is exited before the host controller is allowed to traverse the poll rate level one list.
- A *Save-Place* FSTN's *Back Path Link Pointer* must reference a queue head data structure. The referenced queue head must be reachable from the previous frame list

location. In other words, if the *Save-Place* FSTN is reachable from frame list offset N, then the FSTN's *Back Path Link Pointer* must reference a queue head that is reachable from frame list offset N-1.

Software should make the schedule as efficient as possible. What this means in this context is that software should have no more than one *Save-Place* FSTN reachable in any single frame. Note there is times when two (or more, depending on the implementation) could exist as full/low-speed footprints change with bandwidth adjustments. This could occur, for example when a bandwidth re-balance causes system software to move the *Save-Place* FSTN from one poll rate level to another. During the transition, software must preserve the integrity of the previous schedule until the new schedule is in place.

#### 41.5.3.12.2.4 Tracking Split Transaction Progress for Interrupt Transfers

To correctly maintain the data stream, the host controller must be able to detect and report errors where data is lost.

For interrupt-IN transfers, data is lost when it makes it into the USB 2.0 hub, but the USB 2.0 host system is unable to get it from the USB 2.0 Hub and into the system before it expires from the transaction translator pipeline.

When a lost data condition is detected, the queue must be halted, thus signaling system software to recover from the error. A data-loss condition exists whenever a start-split is issued, accepted and successfully executed by the USB 2.0 Hub, but the complete-splits get unrecoverable errors on the high-speed link, or the complete-splits do not occur at the correct times. One reason complete-splits might not occur at the right time would be due to host-induced system hold-offs that cause the host controller to miss bus transactions because it cannot get timely access to the schedule in system memory.

The same condition can occur for an interrupt-OUT, but the result is not an endpoint halt condition, but rather effects only the progress of the transfer. The queue head has the following fields to track the progress of each split transaction. These fields are used to keep incremental state about which (and when) portions have been executed.

- *C-prog-mask*. This is an eight-bit bit-vector where the host controller keeps track of which complete-splits have been executed. Due to the nature of the Transaction Translator periodic pipeline, the complete-splits need to be executed in-order. The host controller needs to detect when the complete-splits have not been executed in order. This can only occur due to system hold-offs where the host controller cannot get to the memory-based schedule. *C-prog-mask* is a simple bit-vector that the host controller sets one of the *C-prog-mask* bits for each complete-split executed. The bit position is determined by the micro-frame number in which the complete-split was executed. The host controller always checks *C-prog-mask* before executing a

complete-split transaction. If the previous complete-splits have not been executed then it means one (or more) have been skipped and data has potentially been lost.

- *FrameTag*. This field is used by the host controller during the complete-split portion of the split transaction to tag the queue head with the frame number (*H-Frame* number) when the next complete split must be executed.
- *S-bytes*. This field can be used to store the number of data payload bytes sent during the start-split (if the transaction was an OUT). The *S-bytes* field must be used to accumulate the data payload bytes received during the complete-splits (for an IN).

#### 41.5.3.12.2.5 Split Transaction Execution State Machine for Interrupt

In the following presentation, all references to micro-frame are in the context of a micro-frame within an *H-Frame*.

As with asynchronous Full- and Low-speed endpoints, a split-transaction state machine is used to manage the split transaction sequence.

Aside from the fields defined in the queue head for scheduling and tracking the split transaction, the host controller calculates one internal mechanism that is also used to manage the split transaction. The internal calculated mechanism is:

- *cMicroFrameBit* is a single-bit encoding of the current micro-frame number. It is an eight-bit value calculated by the host controller at the beginning of every micro-frame. It is calculated from the three least significant bits of the *FRINDEX* register (that is,  $cMicroFrameBit = (1 \text{ shifted-left}(FRINDEX[2:0]))$ ). The *cMicroFrameBit* has at most one bit asserted, which always corresponds to the current micro-frame number. For example, if the current micro-frame is 0, then *cMicroFrameBit* will equal 00000001b. The variable *cMicroFrameBit* is used to compare against the *S-mask* and *C-mask* fields to determine whether the queue head is marked for a start- or complete-split transaction for the current micro-frame.

The following figure illustrates the state machine for managing a complete interrupt split transaction. There are two phases to each split transaction. The first is a single start-split transaction, which occurs when the *SplitXState* is at *Do\_Start* and the single bit in *cMicroFrameBit* has a corresponding bit active in *QH.S-mask*. The transaction translator does not acknowledge the receipt of the periodic start-split, so the host controller unconditionally transitions the state to *Do\_Complete*. Due to the available jitter in the transaction translator pipeline, there will be more than one complete-split transaction scheduled by software for the *Do\_Complete* state. This translates simply to the fact that there are multiple bits set to a one in the *QH.C-mask* field.

The host controller keeps the queue head in the *Do\_Complete* state until the split transaction is complete (see definition below), or an error condition triggers the *three-strikes-rule* (for example, after the host tries the same transaction three times, and each

encounters an error, the host controller will stop retrying the bus transaction and halt the endpoint, thus requiring system software to detect the condition and perform system-dependent recovery).

Figure 41-23. Split Transaction State Machine for Interrupt

See Previous Section for the frame tag management rules.

Periodic Interrupt - Do Start Split

This is the state software must initialize a full- or low-speed interrupt queue head *StartXState* bit. This state is entered from the Do\_Complete Split state only after the split transaction is complete. This occurs when one of the following events occur: The transaction translator responds to a complete-split transaction with one of the following:

- NAK. A NAK response is a propagation of the full- or low-speed endpoint's NAK response.
- ACK. An ACK response is a propagation of the full- or low-speed endpoint's ACK response. Only occurs on an OUT endpoint.
- DATA 0/1. Only occurs for INs. Indicates that this is the last of the data from the endpoint for this split transaction.
- ERR. The transaction on the low-/full-speed link below the transaction translator had a failure (for example, timeout, bad CRC, etc.).
- NYET (and Last). The host controller issued the last complete-split and the transaction translator responded with a NYET handshake. This means that the start-split was not correctly received by the transaction translator, so it never executed a transaction to the full- or low-speed endpoint, see Section [Periodic Isochronous - Do Complete Split](#) for the definition of 'Last'.

Each time the host controller visits a queue head in this state (once within the Execute Transaction state), it performs the following test to determine whether to execute a start-split.

- *QH.S-mask* is bit-wise anded with *cMicroFrameBit*.

If the result is non-zero, then the host controller will issue a start-split transaction. If the *PIDCode* field indicates an IN transaction, the host controller must zero-out the *QH.S-bytes* field. After the split-transaction has been executed, the host controller sets up state in the queue head to track the progress of the complete-split phase of the split transaction. Specifically, it records the expected frame number into *QH.FrameTag* field (see Section ), set *C-prog-mask* to zero (00h), and exits this state. Note that the host controller must not adjust the value of *CErr* as a result of completion of a start-split transaction.

### Periodic Interrupt - Do Complete Split

This state is entered unconditionally from the Do Start Split state after a start-split transaction is executed on the bus. Each time the host controller visits a queue head in this state (once within the Execute Transaction state), it checks to determine whether a complete-split transaction should be executed now.

There are four tests to determine whether a complete-split transaction should be executed.

- Test A. *cMicroFrameBit* is bit-wise anded with *QH.C-mask* field. A non-zero result indicates that software scheduled a complete-split for this endpoint, during this micro-frame.
- Test B. *QH.FrameTag* is compared with the current contents of *FRINDEX[7:3]*. An equal indicates a match.
- Test C. The complete-split progress bit vector is checked to determine whether the previous bit is set, indicating that the previous complete-split was appropriately executed. An example algorithm for this test is provided below:

```
Algorithm Boolean CheckPreviousBit(QH.C-prog-mask, QH.C-mask, cMicroFrameBit)
Begin
-- Return values:
-- TRUE - no error
-- FALSE - error
--
Boolean rvalue = TRUE;
previousBit = cMicroframeBit logical-rotate-right(1)
-- Bit-wise anding previousBit with C-mask indicates
-- whether there was an intent
-- to send a complete split in the previous micro-frame. So,
-- if the
-- 'previous bit' is set in C-mask, check C-prog-mask to
-- make sure it
-- happened.
If (previousBit bitAND QH.C-mask) then
    If not(previousBit bitAND QH.C-prog-mask) then
        rvalue = FALSE;
    End if
End If
-- If the C-prog-mask already has a one in this bit position,
```

## USB Operation Model

```
-- then an aliasing
-- error has occurred. It will probably get caught by the
-- FrameTag Test, but
-- at any rate it is an error condition that as detectable here
-- should not allow
-- a transaction to be executed.
If (cMicroFrameBit bitAND QH.C-prog-mask) then
  rvalue = FALSE;
End if
return (rvalue)
End Algorithm
```

- Test D. Check to see if a start-split should be executed in this micro-frame. Note this is the same test performed in the Do Start Split state (see Section [Periodic Isochronous - Do Start Split](#)). Whenever it evaluates to TRUE and the controller is NOT processing in the context of a *Recovery Path* mode, it means a start-split should occur in this micro-frame. Test D and Test A evaluating to TRUE at the same time is a system software error. Behavior is undefined.

If (A .and. B .and. C .and. not(D)) then the host controller will execute a complete-split transaction. When the host controller commits to executing the complete-split transaction, it updates *QH.C-prog-mask* by bit-ORing with *cMicroFrameBit*. On completion of the complete-split transaction, the host controller records the result of the transaction in the queue head and sets *QH.FrameTag* to the expected *H-Frame* number (see Section ). The effect to the state of the queue head and thus the state of the transfer depends on the response by the transaction translator to the complete-split transaction. The following responses have the effects (note that any responses that result in decrementing of the *CErr* will result in the queue head being halted by the host controller if the result of the decrement is zero):

- NYET (and Last). On each NYET response, the host controller checks to determine whether this is the last complete-split for this split transaction. Last is defined in this context as the condition where all of the scheduled complete-splits have been executed. If it is the last complete-split (with a NYET response), then the transfer state of the queue head is not advanced (never received any data) and this state exited. The transaction translator must have responded to all the complete-splits with NYETs, meaning that the start-split issued by the host controller was not received. The start-split should be retried at the next poll period.
- The test for whether this is the Last complete split can be performed by XOR *QH.C-mask* with *QH.C-prog-mask*. If the result is all zeros then all complete-splits have been executed. When this condition occurs, the *XactErr* status bit is set to a one and the *CErr* field is decremented.
- NYET (and not Last). See above description for testing for Last. The complete-split transaction received a NYET response from the transaction translator. Do not update any transfer state (except for *C-prog-mask* and *FrameTag*) and stay in this state. The host controller must not adjust *CErr* on this response.

- Transaction Error (XactErr). Timeout, data CRC failure, etc. The *CErr* field is decremented and the *XactErr* bit in the *Status* field is set to a one. The complete split transaction is *immediately* retried (if *CErr* is non-zero). If there is not enough time in the micro-frame to complete the retry and the endpoint is an IN, or *CErr* is decremented to a zero from a one, the queue is halted. If there is not enough time in the micro-frame to complete the retry and the endpoint is an OUT and *CErr* is not zero, then this state is exited (that is, return to Do Start Split). This results in a retry of the entire OUT split transaction, at the next poll period. Refer to Chapter 11 Hubs (specifically the section full- and low-speed Interrupts) in the USB Specification Revision 2.0 for detailed requirements on why these errors must be immediately retried.
- ACK. This can only occur if the target endpoint is an OUT. The target endpoint ACK'd the data and this response is a propagation of the endpoint ACK up to the host controller. The host controller must advance the state of the transfer. The *Current Offset* field is incremented by *Maximum Packet Length* or *Bytes to Transfer*, whichever is less. The field *Bytes To Transfer* is decremented by the same amount. And the data toggle bit (*dt*) is toggled. The host controller will then exit this state for this queue head. The host controller must reload *CErr* with maximum value on this response. Advancing the transfer state may cause other process events such as retirement of the qTD and advancement of the queue (see Section [Managing Control/Bulk/Interrupt Transfers through Queue Heads](#)).
- MDATA. This response will only occur for an IN endpoint. The transaction translator responded with zero or more bytes of data and an MDATA PID. The incremental number of bytes received is accumulated in *QH.S-bytes*. The host controller must not adjust *CErr* on this response.
- DATA0/1. This response may only occur for an IN endpoint. The number of bytes received is added to the accumulated byte count in *QH.S-bytes*. The state of the transfer is advanced by the result and the host controller will exit this state for this queue head.
- Advancing the transfer state may cause other processing events such as retirement of the qTD and advancement of the queue (see Section [Managing Control/Bulk/Interrupt Transfers through Queue Heads](#)).
- If the data sequence PID does not match the expected, the entirety of the data received in this split transaction is ignored, the transfer state is not advanced and this state is exited.
- NAK. The target endpoint Nak'd the full- or low-speed transaction. The state of the transfer is not advanced, and this state is exited. The host controller must reload *CErr* with maximum value on this response.

- **ERR.** There was an error during the full- or low-speed transaction. The ERR status bit is set to a one, *Cerr* is decremented, the state of the transfer is not advanced, and this state is exited.
- **STALL.** The queue is halted (an exit condition of the Execute Transaction state). The status field bits: *Active* bit is set to zero and the *Halted* bit is set to a one and the qTD is retired. Responses which are not enumerated in the list or which are received out of sequence are illegal and may result in undefined host controller behavior. The other possible combinations of tests A, B, C, and D may indicate that data or response was lost. The table below lists the possible combinations and the appropriate action.

**Table 41-48. Interrupt IN/OUT Do Complete Split State Execution Criteria**

Condition	Action	Description
not(A) not(D)	Ignore QHD	Neither a start nor complete-split is scheduled for the current micro-frame. Host controller should continue walking the schedule.
A not(C)	If <i>PIDCode</i> = IN Halt QHD If <i>PIDCode</i> = OUT Retry start-split	Progress bit check failed. These means a complete-split has been missed. There is the possibility of lost data. If <i>PIDCode</i> is an IN, then the Queue head must be halted.  If <i>PIDCode</i> is an OUT, then the transfer state is not advanced and the state exited (for example, start-split is retried). This is a host-induced error and does not effect <i>CERR</i> .  In either case, set the <i>Missed Micro-frame</i> bit in the status field to a one.
A not(B) C	If <i>PIDCode</i> = IN Halt QHD If <i>PIDCode</i> = OUT Retry start-split	<i>QH.FrameTag</i> test failed. This means that exactly one or more <i>H-Frames</i> have been skipped. This means complete-splits and have missed. There is the possibility of lost data. If <i>PIDCode</i> is an IN, then the Queue head must be halted.  If <i>PIDCode</i> is an OUT, then the transfer state is not advanced and the state exited (for example, start-split is retried). This is a host-induced error and does not effect <i>CERR</i> .  In either case, set the <i>Missed Micro-frame</i> bit in the status field to a one.
A B C not(D)	Execute complete-split	This is the non-error case where the host controller executes a complete-split transaction.
D	If <i>PIDCode</i> = IN Halt QHD If <i>PIDCode</i> = OUT Retry start-split	This is a degenerate case where the start-split was issued, but all of the complete-splits were skipped and all possible intervening opportunities to detect the missed data failed to fire. If <i>PIDCode</i> is an IN, then the Queue head must be halted.  If <i>PIDCode</i> is an OUT, then the transfer state is not advanced and the state exited (for example, start-split is retried). This is a host-induced error and does not effect <i>CERR</i> .  In either case, set the <i>Missed Micro-frame</i> bit in the status field to a one. Note: When executing in the context of a <i>Recovery Path</i> mode, the host controller is allowed to process the queue head and take the actions indicated above, or it may wait until the queue head is visited in the

**Table 41-48. Interrupt IN/OUT Do Complete Split State Execution Criteria**

		normal processing mode. Regardless, the host controller must not execute a start-split in the context of a executing in a <i>Recovery Path</i> mode.
--	--	------------------------------------------------------------------------------------------------------------------------------------------------------

### Managing QH.FrameTag Field

The *QH.FrameTag* field in a queue head is completely managed by the host controller. The rules for setting *QH.FrameTag* are simple:

- Rule 1: If transitioning from Do Start Split to Do Complete Split and the current value of *FRINDEX*[2:0] is 6 *QH.FrameTag* is set to *FRINDEX*[7:3] + 1. This accommodates split transactions whose start-split and complete-splits are in different *H-Frames* (case 2a, see [Figure 41-20](#)).
- Rule 2: If the current value of *FRINDEX*[2:0] is 7, *QH.FrameTag* is set to *FRINDEX*[7:3] + 1. This accommodates staying in Do Complete Split for cases 2a, 2b, and 2c ([Figure 41-20](#)).
- Rule 3: If transitioning from Do\_Start Split to Do Complete Split and the current value of *FRINDEX*[2:0] is not 6, or currently in Do Complete Split and the current value of (*FRINDEX*[2:0]) is not 7, *FrameTag* is set to *FRINDEX*[7:3]. This accommodates all other cases ([Figure 41-20](#)).

#### 41.5.3.12.2.6 Rebalancing the periodic schedule

System software must occasionally adjust a periodic queue head's S-mask and C-mask fields during operation.

This need occurs when adjustments to the periodic schedule create a new bandwidth budget and one or more queue head's are assigned new execution footprints (that is, new S-mask and C-mask values).

It is imperative that System software must not update these masks to new values in the midst of a split transaction. In order to avoid any race conditions with the update, the EHCI host controller provides a simple assist to system software. System software sets the *Inactivate-on-next-Transaction* (*I*) bit to a one to signal the host controller that it intends to update the S-mask and C-mask on this queue head. System software will then wait for the host controller to observe the *I-bit* is a one and transition the *Active* bit to a zero. The rules for how and when the host controller sets the *Active* bit to zero are enumerated below:

- If the *Active* bit is a zero, no action is taken. The host controller does not attempt to advance the queue when the *I-bit* is a one.
- If the *Active* bit is a one and the *SplitXState* is DoStart (regardless of the value of *S-mask*), the host controller will simply set *Active* bit to a zero. The host controller is

not required to write the transfer state back to the *current* qTD. Note that if the *S-mask* indicates that a start-split is scheduled for the current micro-frame, the host controller must not issue the start-split bus transaction. It must set the *Active* bit to zero.

System software must save transfer state before setting the *I-bit* to a one. This is required so that it can correctly determine what transfer progress (if any) occurred after the *I-bit* was set to a one and the host controller executed its final bus-transaction and set *Active* to a zero.

After system software has updated the *S-mask* and *C-mask*, it must then reactivate the queue head. Because the *Active* bit and the *I-bit* cannot be updated with the same write, system software needs to use the following algorithm to coherently re-activate a queue head that has been stopped via the *I-bit*.

1. Set the *Halted* bit to a one, then
2. Set the *I-bit* to a zero, then
3. Set the *Active* bit to a one and the *Halted* bit to a zero in the same write.

Setting the *Halted* bit to a one inhibits the host controller from attempting to advance the queue between the time the *I-bit* goes to a zero and the *Active* bit goes to a one.

### 41.5.3.12.3 Split Transaction Isochronous

Full-speed isochronous transfers are managed using the split-transaction protocol through a USB 2.0 transaction translator in a USB2.0 Hub. The EHCI controller utilizes siTD data structure to support the special requirements of isochronous split-transactions.

This data structure uses the scheduling model of isochronous TDs (iTDD, Section [Isochronous \(High-Speed\) Transfer Descriptor \(iTDD\)](#)) (see Section [Managing Isochronous Transfers Using iTDDs](#) for the operational model of iTDDs) with the contiguous data feature provided by queue heads. This simple arrangement allows a single isochronous scheduling model and adds the additional feature that all data received from the endpoint (per split transaction) must land into a contiguous buffer.

#### 41.5.3.12.3.1 Split Transaction Scheduling Mechanisms for Isochronous

Full-speed isochronous transactions are managed through a transaction translator's periodic pipeline. As with full- and low-speed interrupt, system software manages each transaction translator's periodic pipeline by budgeting and scheduling exactly during which micro-frames the start-splits and complete-splits for each full-speed isochronous endpoint occur.

The requirements described in Section [Split Transaction Scheduling Mechanisms for Interrupt](#) apply. The following figure illustrates the general scheduling boundary conditions that are supported by the EHCI periodic schedule. The  $S^X$  and  $C^X$  labels indicate micro-frames where software can schedule start- and complete-splits (respectively). The *H-Frame* boundaries are marked with a large, solid bold vertical line. The *B-Frame* boundaries are marked with a large, bold, dashed line. The bottom of the figure illustrates the relationship of an siTD to the *H-Frame*.

**Figure 41-24. Split Transaction, Isochronous Scheduling Boundary Conditions**

When the endpoint is an isochronous OUT, there are only start-splits, and no complete-splits. When the endpoint is an isochronous IN, there is at most one start-split and one to  $N$  complete-splits. The scheduling boundary cases are:

- *Case 1:* The entire split transaction is completely bounded by an *H-Frame*. For example: the start-splits and complete-splits are all scheduled to occur in the same *H-Frame*.

- *Case 2a*: This boundary case is where one or more (at most two) complete-splits of a split transaction IN are scheduled across an *H-Frame* boundary. This can only occur when the split transaction has the possibility of moving data in *B-Frame*, micro-frames 6 or 7 (*H-Frame* micro-frame 7 or 0). When an *H-Frame* boundary wrap condition occurs, the scheduling of the split transaction spans more than one location in the periodic list. (For example, it takes two siTDs in adjacent periodic frame list locations to fully describe the scheduling for the split transaction.)
- Although the scheduling of the split transaction may take two data structures, all of the complete-splits for each full-speed IN isochronous transaction must use only one data pointer. For this reason, siTDs contain a back pointer, the use of which is described below.
- Software must never schedule full-speed isochronous OUTs across an *H-Frame* boundary.
- *Case 2b*: This case can only occur for a very large isochronous IN. It is the only allowed scenario where a start-split and complete-split for the same endpoint can occur in the same micro-frame. Software must enforce this rule by scheduling the large transaction first. Large is defined to be anything larger than 579 byte maximum packet size.

A subset of the same mechanisms employed by full- and low-speed interrupt queue heads are employed in siTDs to schedule and track the portions of isochronous split transactions. The following fields are initialized by system software to instruct the host controller when to execute portions of the split transaction protocol.

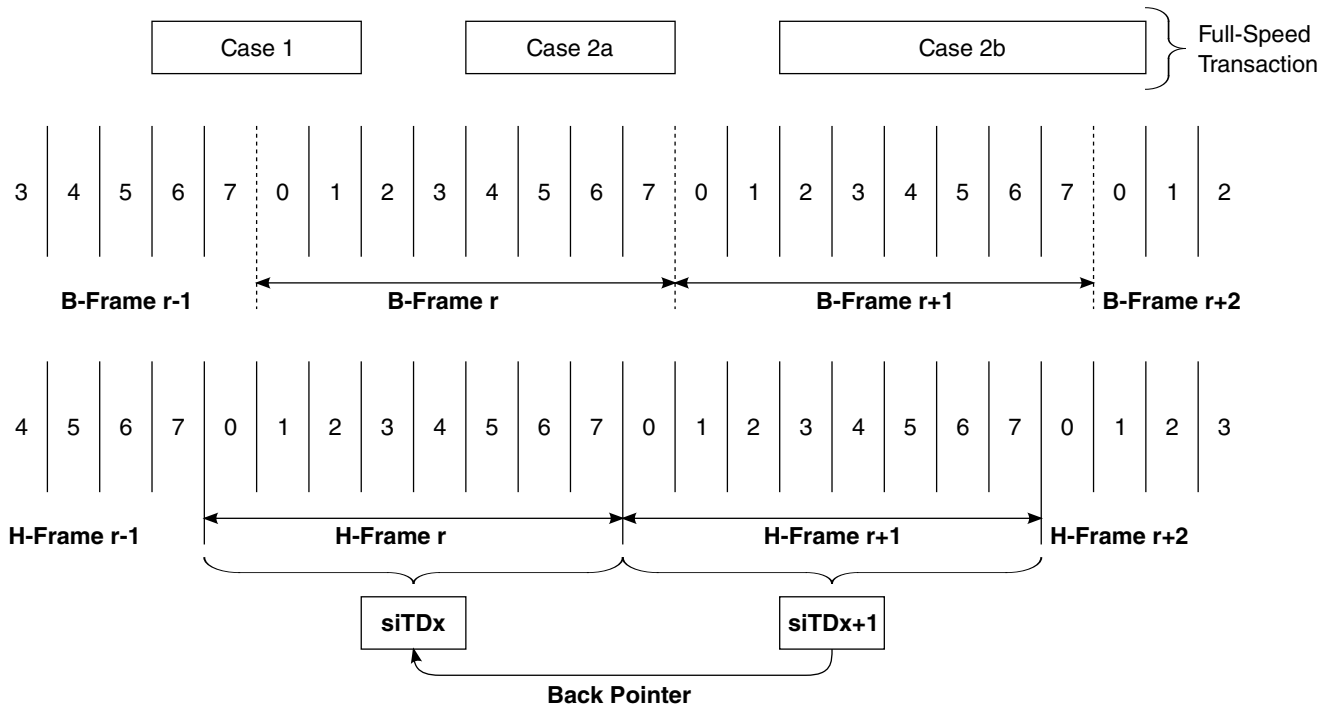

- *SplitXState*. This is a single bit residing in the *Status* field of an siTD (see [Figure 41-25](#)). This bit is used to track the current state of the split transaction. The rules for managing this bit are described in [Section Split Transaction Execution State Machine for Interrupt](#).
- *Frame S-mask*. This is a bit-field where-in system software sets a bit corresponding to the micro-frame (within an *H-Frame*) that the host controller should execute a start-split transaction. This is always qualified by the value of the *SplitXState* bit. For example, referring to the IN example in [Figure 41-24](#), case one, the *S-mask* would have a value of 00000001b indicating that if the siTD is traversed by the host controller, and the *SplitXState* indicates Do Start Split, and the current micro-frame as indicated by `USB_n_FRINDEX[2:0]` is 0, then execute a start-split transaction.
- *Frame C-mask*. This is a bit-field where system software sets one or more bits corresponding to the micro-frames (within an *H-Frame*) that the host controller should execute complete-split transactions. The interpretation of this field is always qualified by the value of the *SplitXState* bit. For example, referring to the IN example in [Figure 41-24](#), case one, the *C-mask* would have a value of 00111100b indicating that if the siTD is traversed by the host controller, and the *SplitXState* indicates Do

Complete Split, and the current micro-frame as indicated by *USB\_n\_FRINDEX*[2:0] is 2, 3, 4, or 5, then execute a complete-split transaction.

- *Back Pointer*. This field in a siTD is used to complete an IN split-transaction using the previous *H-Frame*'s siTD. This is only used when the scheduling of the complete-splits span an *H-Frame* boundary.

There exists a one-to-one relationship between a high-speed isochronous split transaction (including all start- and complete-splits) and one full-speed isochronous transaction. An siTD contains (amongst other things) buffer state and split transaction scheduling information. An siTD's buffer state always maps to one full-speed isochronous data payload. This means that for any full-speed transaction payload, a single siTD's data buffer must be used. This rule applies to both IN and OUTs. An siTD's scheduling information usually also maps to one high-speed isochronous split transaction. The exception to this rule is the *H-Frame* boundary wrap cases mentioned above.

The siTD data structure describes at most, one frame's worth of high-speed transactions and that description is strictly bounded within a frame boundary. The figure below illustrates some examples. On the top are examples of the full-speed transaction footprints for the boundary scheduling cases described above. In the middle are time-frame references for both the *B-Frames* (HS/FS/LS Bus) and the *H-Frames*. On the bottom is illustrated the relationship between the scope of an siTD description and the time references. Each *H-Frame* corresponds to a single location in the periodic frame list. The implication is that each siTD is reachable from a single periodic frame list location at a time.

**Figure 41-25. siTD Scheduling Boundary Examples**

Each case is described below:

- *Case 1:* One siTD is sufficient to describe and complete the isochronous split transaction because the whole isochronous split transaction is tightly contained within a single *H-Frame*.
- *Case 2a, 2b:* Although both INs and OUTs can have these footprints, OUTs always take only one siTD to schedule. However, INs (for these boundary cases) require two siTDs to complete the scheduling of the isochronous split transaction  $siTD_x$  is used to always issue the start-split and the first  $N$  complete-splits. The full-speed transaction (for these cases) can deliver data on the full-speed bus segment during micro-frame 7 of *H-Frame* <sub>$\gamma+1$</sub> , or micro-frame 0 of *H-Frame* <sub>$\gamma+2$</sub> . The complete splits are scheduled using  $siTD_{x+2}$  (not shown). The complete-splits to extract this data must use the buffer pointer from  $siTD_{x+1}$ . The only way for the host controller to reach  $siTD_{x+1}$  from *H-Frame* <sub>$\gamma+2$</sub>  is to use  $siTD_{x+2}$ 's back pointer. The host controller rules for when to use the back pointer are described in Section [Periodic Isochronous - Do Complete Split](#).

Software must apply the following rules when calculating the schedule and linking the schedule data structures into the periodic schedule:

- Software must ensure that an isochronous split-transaction is started so that it will complete before the end of the *B-Frame*.
- Software must ensure that for a single full-speed isochronous endpoint, there is never a start-split and complete-split in *H-Frame, micro-frame 1*. This is mandated as a rule so that case 2a and case 2b can be discriminated. According to the core USB specification, the long isochronous transaction illustrated in Case 2b, could be scheduled so that the start-split was in micro-frame 1 of *H-Frame N* and the last complete-split would need to occur in micro-frame 1 of *H-Frame N+1*. However, it is impossible to discriminate between cases 2a and case 2b, which has significant impact on the complexity of the host controller.

#### 41.5.3.12.3.2 Tracking Split Transaction Progress for Isochronous Transfers

To correctly maintain the data stream, the host controller must be able to detect and report errors where device to host data is lost. Isochronous endpoints do not employ the concept of a halt on error, however the host is required to identify and report per-packet errors observed in the data stream. This includes schedule traversal problems (skipped micro-frames), timeouts and corrupted data received.

In similar kind to interrupt split-transactions, the portions of the split transaction protocol must execute in the micro-frames they are scheduled. The queue head data structure used to manage full- and low-speed interrupt has several mechanisms for tracking when portions of a transaction have occurred. Isochronous transfers use siTDs, for their transfers, and the data structures are only reachable via the schedule in the exact micro-frame in which they are required (so all the mechanism employed for tracking in queue heads is not required for siTDs). Software has the option of reusing siTD several times in the complete periodic schedule. However, it must ensure that the results of split transaction *N* are consumed and the siTD reinitialized (activated) before the host controller gets back to the siTD (in a future micro-frame).

Split-transaction isochronous OUTs utilize a low-level protocol to indicate which portions of the split transaction data have arrived. Control over the low-level protocol is exposed in an siTD via the fields *Transaction Position (TP)* and *Transaction Count (T-count)*. If the entire data payload for the OUT split transaction is larger than 188 bytes, there will be more than one start-split transaction, each of which require proper annotation. If host hold-offs occur, then the sequence of annotations received from the host will not be complete, which is detected and handled by the transaction translator. See Section [Periodic Isochronous - Do Start Split](#) for a description on how these fields are used during a sequence of start-split transactions.

The fields *siTD.T-Count* and *siTD.TP* are used by the host controller to drive and sequence the transaction position annotations. It is the responsibility of system software to properly initialize these fields in each siTD. Once the budget for a split-transaction

isochronous endpoint is established, *S-mask*, *T-Count*, and *TP* initialization values for all the siTD associated with the endpoint are constant. They remain constant until the budget for the endpoint is recalculated by software and the periodic schedule adjusted.

For IN-endpoints, the transaction translator simply annotates the response data packets with enough information to allow the host controller to identify the last data. As with split transaction Interrupt, it is the host controller's responsibility to detect when it has missed an opportunity to execute a complete-split. The following field in the siTD is used to track and detect errors in the execution of a split transaction for an IN isochronous endpoint.

- *C-prog-mask*. This is an eight-bit bit-vector where the host controller keeps track of which complete-splits have been executed. Due to the nature of the Transaction Translator periodic pipeline, the complete-splits need to be executed in-order. The host controller needs to detect when the complete-splits have not been executed in order. This can only occur due to system hold-offs where the host controller cannot get to the memory-based schedule. *C-prog-mask* is a simple bit-vector that the host controller sets a bit for each complete-split executed. The bit position is determined by the micro-frame (USB\_n\_FRINDEX[2:0]) number in which the complete-split was executed. The host controller always checks *C-prog-mask* before executing a complete-split transaction. If the previous complete-splits have not been executed, then it means one (or more) have been skipped and data has potentially been lost. System software is required to initialize this field to zero before setting an siTD's *Active* bit to a one.

If a transaction translator returns with the final data before all of the complete-splits have been executed, the state of the transfer is advanced so that the remaining complete-splits are not executed. Refer to Section [Asynchronous - Do Complete Split](#) for a description on how the state of the transfer is advanced. It is important to note that an IN siTD is retired based solely on the responses from the Transaction Translator to the complete-split transactions. This means, for example, that it is possible for a transaction translator to respond to a complete-split with an MDATA PID. The number of bytes in the MDATA's data payload could cause the siTD field *Total Bytes to Transfer* to decrement to zero. This response can occur, before all of the scheduled complete-splits have been executed. In other interface, data structures (for example, high-speed data streams through queue heads), the transition of *Total Bytes to Transfer* to zero signals the end of the transfer and results in setting of the *Active* bit to zero. However, in this case, the result has not been delivered by the Transaction Translator and the host must continue with the next complete-split transaction to extract the residual transaction state. This scenario occurs because of the pipeline rules for a Transaction Translator (see Chapter 11 of the Universal Serial Bus Revision 2.0). In summary the periodic pipeline rules require that on a micro-frame boundary, the Transaction Translator will hold the final two bytes received (if it has not seen an End Of Packet (EOP)) in the full-speed bus pipe stage and give the

remaining bytes to the high-speed pipeline stage. At the micro-frame boundary, the Transaction Translator could have received the entire packet (including both CRC bytes) but not received the packet EOP. In the next micro-frame, the Transaction Translator will respond with an MDATA and send all of the data bytes (with the two CRC bytes being held in the full-speed pipeline stage). This could cause the siTD to decrement its *Total Bytes to Transfer* field to zero, indicating it has received all expected data. The host must still execute one more (scheduled) complete-split transaction in order to extract the results of the full-speed transaction from the Transaction Translator (for example, the Transaction Translator may have detected a CRC failure, and this result must be forwarded to the host).

If the host experiences hold-offs that cause the host controller to skip one or more (but not all) scheduled split transactions for an isochronous OUT, then the protocol to the transaction translator will not be consistent and the transaction translator will detect and react to the problem. Likewise, for host hold-offs that cause the host controller to skip one or more (but not all) scheduled split transactions for an isochronous IN, the *C-prog-mask* is used by the host controller to detect errors. However, if the host experiences a hold-off that causes it to skip all of an siTD, or an siTD expires during a host hold off (for example, a hold-off occurs and the siTD is no longer reachable by the host controller in order for it to report the hold-off event), then system software must detect that the siTDs have not been processed by the host controller (that is, state not advanced) and report the appropriate error to the client driver.

#### 41.5.3.12.3.3 Split Transaction Execution State Machine for Isochronous

In the following presentation, all references to micro-frame are in the context of a micro-frame within an *H-Frame*.

If the *Active* bit in the *Status* byte is a zero, the host controller will ignore the siTD and continue traversing the periodic schedule. Otherwise the host controller will process the siTD as specified below. A split transaction state machine is used to manage the split-transaction protocol sequence. The host controller uses the fields defined in Section [Tracking Split Transaction Progress for Interrupt Transfers](#), plus the variable *cMicroFrameBit* defined in Section [Split Transaction Execution State Machine for Interrupt](#) to track the progress of an isochronous split transaction. The figure below illustrates the state machine for managing an siTD through an isochronous split transaction. Bold, dotted circles denote the state of the *Active* bit in the *Status* field of a siTD. The Bold, dotted arcs denote the transitions between these states. Solid circles denote the states of the split transaction state machine and the solid arcs denote the transitions between these states. Dotted arcs and boxes reference actions that take place either as a result of a transition or from being in a state.

Figure 41-26. Split Transaction State Machine for Isochronous

#### 41.5.3.12.3.4 Periodic Isochronous - Do Start Split

Isochronous split transaction OUTs use only this state.

An siTD for a split-transaction isochronous IN is either initialized to this state, or the siTD transitions to this state from Do Complete Split when a case 2a (IN) or 2b scheduling boundary isochronous split-transaction completes.

Each time the host controller reaches an active siTD in this state, it checks the *siTD.S-mask* against *cMicroFrameBit*. If there is a one in the appropriate position, the siTD will execute a start-split transaction. By definition, the host controller cannot *reach* an siTD at the wrong time. If the *I/O* field indicates an IN, then the start-split transaction includes only the extended token plus the full-speed token. Software must initialize the *siTD.Total Bytes To Transfer* field to the number of bytes expected. This is usually the maximum packet size for the full-speed endpoint. The host controller exits this state when the start-split transaction is complete.

The remainder of this section is specific to an isochronous OUT endpoint (that is, the *I/O* field indicates an OUT). When the host controller executes a start-split transaction for an isochronous OUT it includes a data payload in the start-split transaction. The memory

buffer address for the data payload is constructed by concatenating *siTD.Current Offset* with the page pointer indicated by the page selector field (*siTD.P*). A zero in this field selects Page 0 and a 1 selects Page 1. During the start-split for an OUT, if the data transfer crosses a page boundary during the transaction, the host controller must detect the page cross, update the *siTD.P*-bit from a zero to a one, and begin using the *siTD.Page 1* with *siTD.Current Offset* as the memory address pointer. The field *siTD.TP* is used to annotate each start-split transaction with the indication of which part of the split-transaction data the current payload represents (ALL, BEGIN, MID, END). In all cases the host controller simply uses the value in *siTD.TP* to mark the start-split with the correct transaction position code.

*T-Count* is always initialized to the number of start-splits for the current frame. *TP* is always initialized to the first required transaction position identifier. The scheduling boundary case (see [Figure 41-25](#)) is used to determine the initial value of *TP*. The initial cases are summarized in the following table.

**Table 41-49. Initial Conditions for OUT siTD's TP and T-count Fields**

Case	T-count	TP	Description
1, 2a	=1	ALL	When the OUT data payload is less than (or equal to) 188 bytes, only one start-split is required to move the data. The one start-split must be marked with an ALL.
1, 2a	!=1	BEGIN	When the OUT data payload is greater than 188 bytes more than one start-split must be used to move the data. The initial start-split must be marked with a BEGIN.

After each start-split transaction is complete, the host controller updates *T-Count* and *TP* appropriately so that the next start-split is correctly annotated.

The table below illustrates all of the *TP* and *T-count* transitions, which must be accomplished by the host controller.

**Table 41-50. Transaction Position (TP)/Transaction Count (T-Count) Transition Table**

TP	T-count next	TP next	Description
ALL	0	N/A	Transition from ALL, to done.
BEGIN	1	END	Transition from BEGIN to END. Occurs when <i>T-count</i> starts at 2.
BEGIN	!=1	MID	Transition from BEGIN to MID. Occurs when <i>T-count</i> starts at greater than 2.
MID	!=1	MID	<i>TP</i> stays at MID while <i>T-count</i> is not equal to 1 (that is, greater than 1). This case can occur for any of the scheduling boundary cases where the <i>T-count</i> starts greater than 3.
MID	1	END	Transition from MID to END. This case can occur for any of the scheduling boundary cases where the <i>T-count</i> starts greater than 2.

The start-split transactions do not receive a handshake from the transaction translator, so the host controller always advances the transfer state in the siTD after the bus transaction is complete. To advance the transfer state the following operations take place:

- The *siTD.Total Bytes To Transfer* and the *siTD.Current Offset* fields are adjusted to reflect the number of bytes transferred.
- The *siTD.P* (page selector) bit is updated appropriately.
- The *siTD.TP* and *siTD.T-count* fields are updated appropriately as defined in [Table 41-50](#).

These fields are then written back to the memory based siTD. The *S-mask* is fixed for the life of the current budget. As mentioned above, *TP* and *T-count* are set specifically in each siTD to reflect the data to be sent from this siTD. Therefore, regardless of the value of *S-mask*, the actual number of start-split transactions depends on *T-count* (or equivalently, *Total Bytes to Transfer*). The host controller must set the *Active* bit to a zero when it detects that all of the schedule data has been sent to the bus. The preferred method is to detect when *T-Count* decrements to zero as a result of a start-split bus transaction. Equivalently, the host controller can detect when *Total Bytes to Transfer* decrements to zero. Either implementation must ensure that if the initial condition is *Total Bytes to Transfer* equal to zero and *T-count* is equal to a one, then the host controller will issue a single start-split, with a zero-length data payload. Software must ensure that *TP*, *T-count* and *Total Bytes to Transfer* are set to deliver the appropriate number of bus transactions from each siTD. An inconsistent combination will yield undefined behavior.

If the host experiences hold-offs that cause the host controller to skip start-split transactions for an OUT transfer, the state of the transfer will not progress appropriately. The transaction translator will observe protocol violations in the arrival of the start-splits for the OUT endpoint (that is, the transaction position annotation will be incorrect as received by the transaction translator).

Example scenarios are described in Section [Split Transaction for Isochronous - Processing Examples](#).

A host controller implementation can optionally track the progress of an OUT split transaction by setting appropriate bits in the *siTD.C-prog-mask* as it executes each scheduled start-split. The *checkPreviousBit()* algorithm defined in [Periodic Isochronous - Do Complete Split](#) can be used prior to executing each start-split to determine whether start-splits were skipped. The host controller can use this mechanism to detect missed micro-frames. It can then set the siTD's *Active* bit to zero and stop execution of this siTD. This saves on both memory and high-speed bus bandwidth.

### 41.5.3.12.3.5 Periodic Isochronous - Do Complete Split

This state is only used by a split-transaction isochronous IN endpoint.

This state is entered unconditionally from the Do Start State after a start-split transaction is executed for an IN endpoint. Each time the host controller visits an siTD in this state, it conducts a number of tests to determine whether it should execute a complete-split transaction. The individual tests are listed below. The sequence they are applied depends on which micro-frame the host controller is currently executing which means that the tests might not be applied until after the siTD referenced from the back pointer has been fetched.

- Test A. *cMicroFrameBit* is bit-wise anded with *siTD.C-mask* field. A non-zero result indicates that software scheduled a complete-split for this endpoint, during this micro-frame. This test is always applied to a newly fetched siTD that is in this state.
- Test B. The *siTD.C-prog-mask* bit vector is checked to determine whether the previous complete splits have been executed. An example algorithm is below (this is slightly different than the algorithm used in Section [Periodic Isochronous - Do Complete Split](#)). The sequence in which this test is applied depends on the current value of *USB\_n\_FRINDEX[2:0]*. If *USB\_n\_FRINDEX[2:0]* is 0 or 1, it is not applied until the back pointer has been used. Otherwise it is applied immediately.

Algorithm Boolean CheckPreviousBit(*siTD.C-prog-mask*, *siTD.C-mask*, *cMicroFrameBit*)

Begin

```

Boolean rvalue = TRUE;
previousBit = cMicroFrameBit rotate-right(1)
-- Bit-wise anding previousBit with C-mask indicates whether there was an intent
-- to send a complete split in the previous micro-frame. So, if the
-- 'previous bit' is set in C-mask, check C-prog-mask to make sure it
-- happened.
if previousBit bitAND siTD.C-mask then
    if not (previousBit bitAND siTD.C-prog-mask) then
        rvalue = FALSE
    End if
End if
Return rvalue

```

End Algorithm

If Test A is true and *USB\_n\_FRINDEX[2:0]* is zero or one, then this is a case 2a or 2b scheduling boundary (see [Figure 41-24](#)). See Section [Periodic Isochronous - Do Complete Split](#) for details in handling this condition.

If Test A and Test B evaluate to true, then the host controller will execute a complete-split transaction using the transfer state of the current siTD. When the host controller commits to executing the complete-split transaction, it updates *QH.C-prog-mask* by bit-ORing with *cMicroFrameBit*. The transfer state is advanced based on the completion status of the complete-split transaction. To advance the transfer state of an IN siTD, the host controller must:

- Decrement the number of bytes received from *siTD.Total Bytes To Transfer*,
- Adjust *siTD.Current Offset* by the number of bytes received,

- Adjust *siTD.P* (page selector) field if the transfer caused the host controller to use the next page pointer, and
- Set any appropriate bits in the *siTD.Status* field, depending on the results of the transaction.

Note that if the host controller encounters a condition where *siTD.Total Bytes To Transfer* is zero, and it receives more data, the host controller must not write the additional data to memory. The *siTD.Status.Active* bit must be set to zero and the *siTD.Status.Babble Detected* bit must be set to a one. The fields *siTD.Total Bytes To Transfer*, *siTD.Current Offset*, and *siTD.P* (page selector) are not required to be updated as a result of this transaction attempt.

The host controller must accept (assuming good data packet CRC and sufficient room in the buffer as indicated by the value of *siTD.Total Bytes To Transfer*) MDATA and DATA0/1 data payloads up to and including 192 bytes. A host controller implementation may optionally set *siTD.Status Active* to a zero and *siTD.Status.Babble Detected* to a one when it receives and MDATA or DATA0/1 with a data payload of more than 192 bytes. The following responses have the noted effects:

- ERR. The full-speed transaction completed with a time-out or bad CRC and this is a reflection of that error to the host. The host controller sets the *ERR* bit in the *siTD.Status* field and sets the *Active* bit to a zero.
- Transaction Error (XactErr). The complete-split transaction encounters a Timeout, CRC16 failure, etc. The *siTD.Status* field *XactErr* field is set to a one and the complete-split transaction must be retried immediately. The host controller must use an internal error counter to count the number of retries as a counter field is not provided in the siTD data structure. The host controller will not retry more than two times. If the host controller exhausts the retries or the end of the micro-frame occurs, the *Active* bit is set to zero.
- DATAx (0 or 1). This response signals that the final data for the split transaction has arrived. The transfer state of the siTD is advanced and the *Active* bit is set to a zero. If the *Bytes To Transfer* field has not decremented to zero (including the reception of the data payload in the DATAx response), then less data than was expected, or allowed for was actually received. This *short packet* event does not set the USBINT status bit in the USBSTS register to a one. The host controller will not detect this condition.
- NYET (and Last). On each NYET response, the host controller also checks to determine whether this is the last complete-split for this split transaction. Last was defined in Section [Periodic Isochronous - Do Complete Split](#) . If it is the last complete-split (with a NYET response), then the transfer state of the siTD is not advanced (never received any data) and the *Active* bit is set to a zero. No bits are set in the *Status* field because this is essentially a skipped transaction. The transaction translator must have responded to all the scheduled complete-splits with NYETs,

meaning that the start-split issued by the host controller was not received. This result should be interpreted by system software as if the transaction was completely skipped. The test for whether this is the last complete split can be performed by XORing *C-mask* with *C-prog-mask*. A zero result indicates that all complete-splits have been executed.

- **MDATA (and Last).** See above description for testing for Last. This can only occur when there is an error condition. Either there has been a babble condition on the full-speed link, which delayed the completion of the full-speed transaction, or software set up the *S-mask* and/or *C-masks* incorrectly. The host controller must set *XactErr* bit to a one and the *Active* bit is set to a zero.
- **NYET (and not Last).** See above description for testing for Last. The complete-split transaction received a NYET response from the transaction translator. Do not update any transfer state (except for *C-prog-mask*) and stay in this state.
- **MDATA (and not Last).** The transaction translator responds with an MDATA when it has partial data for the split transaction. For example, the full-speed transaction data payload spans from micro-frame *X* to *X+1* and during micro-frame *X*, the transaction translator will respond with an MDATA and the data accumulated up to the end of micro-frame *X*. The host controller advances the transfer state to reflect the number of bytes received.

If Test A succeeds, but Test B fails, it means that one or more of the complete-splits have been skipped. The host controller sets the *Missed Micro-Frame* status bit and sets the *Active* bit to a zero.

#### 41.5.3.12.3.6 Complete-Split for Scheduling Boundary Cases 2a, 2b

Boundary cases 2a and 2b (INs only) (see [Figure 41-24](#)) require that the host controller use the transaction state context of the previous siTD to finish the split transaction. The table below enumerates the transaction state fields.

**Table 41-51. Summary siTD Split Transaction State**

Buffer State	Status	Execution Progress
Total Bytes To Transfer	All bits in the status field	C-prog-mask
P (page select)		
Current Offset		
TP (transaction position)		
T-count (transaction count)		

#### NOTE

*TP* and *T-count* are used only for Host to Device (OUT) endpoints.

If software has budgeted the schedule of this data stream with a frame wrap case, then it must initialize the *siTD.Back Pointer* field to reference a valid siTD and will have the *siTD.Back Pointer.T-bit* in the *siTD.Back Pointer*

field set to a zero. Otherwise, software must set the *siTD.Back Pointer.T-bit* in the *siTD.Back Pointer* field to a one. The host controller's rules for interpreting when to use the *siTD.Back Pointer* field are listed below. These rules apply only when the siTD's *Active* bit is a one and the *SplitXState* is Do Complete Split.

- When *cMicroFrameBit* is a 1h and the *siTDX.Back Pointer.T-bit* is a zero, or
- If *cMicroFrameBit* is a 2h and *siTDX.S-mask[0]* is a zero

When either of these conditions apply, then the host controller must use the transaction state from *siTD<sub>X-1</sub>*.

In order to access *siTD<sub>X-1</sub>*, the host controller reads on-chip the siTD referenced from *siTD<sub>X</sub>.Back Pointer*.

The host controller must save the entire state from *siTD<sub>X</sub>* while processing *siTD<sub>X-1</sub>*. This is to accommodate for case 2b processing. The host controller must not recursively walk the list of *siTD.Back Pointers*.

If *siTD<sub>X-1</sub>* is active (*Active* bit is a one and *SplitXStat* is Do Complete Split), then both Test A and Test B are applied as described above. If these criteria to execute a complete-split are met, the host controller executes the complete split and evaluates the results as described above. The transaction state (see [Table 41-51](#)) of *siTD<sub>X-1</sub>* is appropriately advanced based on the results and written back to memory. If the resultant state of *siTD<sub>X-1</sub>*'s *Active* bit is a one, then the host controller returns to the context of *siTD<sub>X</sub>*, and follows its next pointer to the next schedule item. No updates to *siTD<sub>X</sub>* are necessary.

If *siTD<sub>X-1</sub>* is active (*Active* bit is a one and *SplitXStat* is Do Start Split), then the host controller must set *Active* bit to a zero and *Missed Micro-Frame* status bit to a one and the resultant status written back to memory.

If *siTD<sub>X-1</sub>*'s *Active* bit is a zero, (because it was zero when the host controller first visited *siTD<sub>X-1</sub>* via *siTD<sub>X</sub>*'s back pointer, it transitioned to zero as a result of a detected error, or the results of *siTD<sub>X-1</sub>*'s complete-split transaction transitioned it to zero), then the host controller returns to the context of *siTD<sub>X</sub>* and transitions its *SplitXState* to Do Start Split. The host controller then determines whether the case 2b start split boundary condition exists (that is, if *cMicroframeBit* is a 1b and *siTD<sub>X</sub>.S-mask[0]* is a 1b). If this criterion is met the host controller immediately executes a start-split transaction and appropriately advances the transaction state of *siTD<sub>X</sub>*, then follows *siTD<sub>X</sub>.Next Pointer* to the next schedule item. If the criterion is not met, the host controller simply follows *siTD<sub>X</sub>.Next Pointer* to the next schedule item. Note that in the case of a 2b boundary case, the split-transaction of *siTD<sub>X-1</sub>* will have its *Active* bit set to zero when the host controller returns

to the context of  $siTD_x$ . Also, note that software should not initialize an  $siTD$  with  $C$ -mask bits 0 and 1 set to a one and an  $S$ -mask with bit zero set to a one. This scheduling combination is not supported and the behavior of the host controller is undefined.

#### 41.5.3.12.3.7 Split Transaction for Isochronous - Processing Examples

There is an important difference between how the hardware/software manages the isochronous split transaction state machine and how it manages the asynchronous and interrupt split transaction state machines.

The asynchronous and interrupt split transaction state machines are encapsulated within a single queue head. The progress of the data stream depends on the progress of each split transaction. In some respects, the split-transaction state machine is sequenced via the Execute Transaction queue head traversal state machine (see [Figure 41-17](#)).

Isochronous is a pure time-oriented transaction/data stream. The interface data structures are optimized to efficiently describe transactions that need to occur at specific times. The isochronous split-transaction state machine must be managed across these time-oriented data structures. This means that system software must correctly describe the scheduling of split-transactions across more than one data structure.

Then the host controller must make the appropriate state transitions at the appropriate times, in the correct data structures.

For example, the table below illustrates a couple of frames worth of scheduling required to schedule a case 2a full-speed isochronous data stream.

**Table 41-52. Example Case 2a - Software Scheduling  $siTD$ s for an IN Endpoint**

siTDX		Micro-Frames								Initial
#	Masks	0	1	2	3	4	5	6	7	SplitXState
X	S-Mask	-	-	-	-	1	-	-	-	Do Start Split
	C-Mask	1	1	-	-	-	-	1	1	
X+1	S-Mask	-	-	-	-	1	-	-	-	Do Complete Split
	C-Mask	1	1					1	1	
X+2	S-Mask	-	-	-	-	1	-	-	-	Do Complete Split
	C-Mask	1	1					1	1	
X+3	S-Mask	Repeats previous pattern								Do Complete Split
	C-Mask									

This example shows the first three siTDs for the transaction stream. Because this is the case-2a frame-wrap case, *S-masks* of all siTDs for this endpoint have a value of 10h (a one bit in micro-frame 4) and *C-mask* value of C3h (one-bits in micro-frames 0,1, 6 and 7). Additionally, software ensures that the *Back Pointer* field of each siTD references the appropriate siTD data structure (and the *Back PointerT-bits* are set to zero).

The initial *SplitXState* of the first siTD is Do Start Split. The host controller will visit the first siTD eight times during frame X. The C-mask bits in micro-frames 0 and 1 are ignored because the state is Do Start Split. During micro-frame 4, the host controller determines that it can run a start-split (and does) and changes *SplitXState* to Do Complete Split. During micro-frames 6 and 7, the host controller executes complete-splits. Notice the siTD for frame X+1 has its *SplitXState* initialized to Do Complete Split. As the host controller continues to traverse the schedule during *H-Frame* X+1, it will visit the second siTD eight times. During micro-frames 0 and 1 it will detect that it must execute complete-splits.

During *H-Frame* X+1, micro-frame 0, the host controller detects that siTD<sub>X+1</sub>'s *Back Pointer.T-bit* is a zero, saves the state of siTD<sub>X+1</sub> and fetches siTD<sub>X</sub>. It executes the complete split transaction using the transaction state of siTD<sub>X</sub>. If the siTD<sub>X</sub> split transaction is complete, siTD's *Active* bit is set to zero and results written back to siTD<sub>X</sub>. The host controller retains the fact that siTD<sub>X</sub> is retired and transitions the *SplitXState* in the siTD<sub>X+1</sub> to Do Start Split. At this point, the host controller is prepared to execute the start-split for siTD<sub>X+1</sub> when it reaches micro-frame 4. If the split-transaction completes early (transaction-complete is defined in Section [Periodic Isochronous - Do Complete Split](#)), that is, before all the scheduled complete-splits have been executed, the host controller will transition *siTD<sub>X</sub>.SplitXState* to Do Start Split early and naturally skip the remaining scheduled complete-split transactions. For this example, siTD<sub>X+1</sub> does not receive a DATA0 response until *H-Frame* X+2, micro-frame 1.

During *H-Frame* X+2, micro-frame 0, the host controller detects that siTD<sub>X+2</sub>'s *Back Pointer.T-bit* is a zero, saves the state of siTD<sub>X+2</sub> and fetches siTD<sub>X+1</sub>. As described above, it executes another split transaction, receives an MDATA response, updates the transfer state, but does not modify the *Active* bit. The host controller returns to the context of siTD<sub>X+2</sub>, and traverses its next pointer without any state change updates to siTD<sub>X+2</sub>. S

During *H-Frame* X+2, micro-frame 1, the host controller detects siTD<sub>X+2</sub>'s *S-mask[0]* is a zero, saves the state of siTD<sub>X+2</sub> and fetches siTD<sub>X+1</sub>. It executes another complete-split transaction, receives a DATA0 response, updates the transfer state and sets the *Active* bit to a zero. It returns to the state of siTD<sub>X+2</sub> and changes its *SplitXState* to Do Start Split. At this point, the host controller is prepared to execute start-splits for siTD<sub>X+2</sub> when it reaches micro-frame 4.

### 41.5.3.13 Host Controller Pause

When the host controller's *HCHalted* bit in the USBSTS register is a zero, the host controller is sending SOF (Start OF Frame) packets down all enabled ports.

When the schedules are enabled, the EHCI host controller will access the schedules in main memory each micro-frame. This constant pinging of main memory is known to create Arm platform power management problems for mobile systems. Specifically, mobile systems aggressively manage the state of the Arm platform, based on recent history usage. In the more aggressive power saving modes, the Arm platform can disable its caches. Current PC architectures assume that bus-master accesses to main memory must be cache-coherent. So, when bus masters are busy touching memory, the Arm platform power management software can detect this activity over time and inhibit the transition of the Arm platform into its lowest power savings mode. USB controllers are bus-masters and the frequency at which they access their memory-based schedules keeps the Arm platform power management software from placing the Arm platform into its lowest power savings state.

USB Host controllers don't access main memory when they are suspended. However, there are a variety of reasons why placing the USB controllers into suspend won't work, but they are beyond the scope of this document. The base requirement is that the USB controller needs to be kept out of main memory, while at the same time, the USB bus is kept from going into suspend.

EHCI controllers provide a large-grained mechanism that can be manipulated by system software to change the memory access pattern of the host controller. System software can manipulate the schedule enable bits in the USBCMD register to turn on/off the scheduling traversal. A software heuristic can be applied to implement an on/off duty cycle that allows the USB to make reasonable progress and allow the Arm platform power management to get the Arm platform into its lowest power state. This method is not intended to be applied at all times to throttle USB, but should only be applied in very specific configurations and usage loads. For example, when only a keyboard or mouse is attached to the USB, the heuristic could detect times when the USB is attempting to move data only very infrequently and can adjust the duty cycle to allow the Arm platform to reach its low power state for longer periods of time. Similarly, it could detect increases in the USB load and adjust the duty cycle appropriately, even to the point where the schedules are never disabled. The assumption here is that the USB is moving data and the Arm platform will be required to process the data streams.

It is suggested that in order to provide a complete solution for the system, the companion host controllers should also provide a similar method to allow system software to inhibit the companion host controller from accessing its shared memory based data structures (schedule lists or otherwise).

#### 41.5.3.14 Port Test Modes -Host Operational Model

EHCI host controllers must implement the port test modes Test J\_State, Test K\_State, Test\_Packet, Test Force\_Enable, and Test SEO\_NAK as described in the USB Specification Revision 2.0.

The system is only allowed to test ports that are owned by the EHCI controller (for example, *CF-bit* is a one and *PortOwner* bit is a zero). System software is allowed to have at most one port in test mode at a time. Placing more than one port in test mode will yield undefined results. The required, per port test sequence is (assuming the *CF-bit* in the USB\_n\_CONFIGFLAG register is a one):

- Disable the periodic and asynchronous schedules by setting the *Asynchronous Schedule Enable* and *Periodic Schedule Enable* bits in the USBCMD register to a zero.
- Place all enabled root ports into the suspended state by setting the *Suspend* bit in each appropriate USB\_n\_PORTSC register to a one.
- Set the *Run/Stop* bit in the USBCMD register to a zero and wait for the *HCHalted* bit in the USBSTS register, to transition to a one. Note that an EHCI host controller implementation may optionally allow port testing with the *Run/Stop* bit set to a one. However, all host controllers must support port testing with *Run/Stop* set to a zero and *HCHalted* set to a one.
- Set the *Port Test Control* field in the port under test PORTSC register to the value corresponding to the desired test mode. If the selected test is Test\_Force\_Enable, then the *Run/Stop* bit in the USBCMD register must then be transitioned back to one, in order to enable transmission of SOFs out of the port under test.
- When the test is complete, system software must ensure the host controller is halted (*HCHalted* bit is a one) then it terminates and exits test mode by setting *HCRreset* to a one.

#### 41.5.3.15 Interrupts-Host Operational Model

The EHCI Host Controller hardware provides interrupt capability based on a number of sources.

There are several general groups of interrupt sources:

- Interrupts as a result of executing transactions from the schedule (success and error conditions),
- Host controller events (Port change events, etc.), and
- Host Controller error events

All transaction-based sources are maskable through the Host Controller's Interrupt Enable register (USBINTR, see Section [Interrupt Enable Register \(USB\\_nUSBINTR\)](#)).

Additionally, individual transfer descriptors can be marked to generate an interrupt on completion. This section describes each interrupt source and the processing that occurs in response to the interrupt.

During normal operation, interrupts may be immediate or deferred until the next interrupt threshold occurs. The interrupt threshold is a tunable parameter via the *Interrupt Threshold Control* field in the USBCMD register. The value of this register controls when the host controller will generate an interrupt on behalf of normal transaction execution. When a transaction completes during an interrupt interval period, the interrupt signaling the completion of the transfer will not occur until the interrupt threshold occurs. For example, the default value is eight micro-frames. This means that the host controller will not generate interrupts any more frequently than once every eight micro-frames.

Section [Host System Error](#) details effects of a host system error.

If an interrupt has been scheduled to be generated for the current interrupt threshold interval, the interrupt is not signaled until after the status for the last complete transaction in the interval has been written back to host memory. This may sometimes result in the interrupt not being signaled until the next interrupt threshold.

Initial interrupt processing is the same, regardless of the reason for the interrupt. When an interrupt is signaled by the hardware, Arm platform control is transferred to host controller's USB interrupt handler. The precise mechanism to accomplish the transfer is OS specific. For this discussion it is just assumed that control is received. When the interrupt handler receives control, its first action is to read the USBSTS (USB Status Register). It then acknowledges the interrupt by clearing all of the interrupt status bits by writing ones to these bit positions. The handler then determines whether the interrupt is due to schedule processing or some other event. After acknowledging the interrupt, the handler (via an OS-specific mechanism), schedules a deferred procedure call (DPC) which will execute later. The DPC routine processes the results of the schedule execution. The precise mechanisms used are beyond the scope of this document.

Note: the host controller is not required to de-assert a currently active interrupt condition when software sets the interrupt enables (in the USBINR register, see Section [Interrupt Enable Register \(USB\\_nUSBINTR\)](#)) to a zero. The only reliable method software should use for acknowledging an interrupt is by transitioning the appropriate status bits in the USBSTS register (Section [USB Status Register \(USB\\_nUSBSTS\)](#)) from a one to a zero.

### 41.5.3.15.1 Transfer/Transaction Based Interrupts

These interrupt sources are associated with transfer and transaction progress. They are all dependent on the next interrupt threshold.

#### 41.5.3.15.1.1 Transaction Error

A transaction error is any error that caused the host controller to think that the transfer did not complete successfully.

The table below lists the events/responses that the host can observe as a result of a transaction. The effects of the error counter and interrupt status are summarized in the following paragraphs. Most of these errors set the *XactErr* status bit in the appropriate interface data structure.

There is a small set of protocol errors that relate only when executing a queue head and fit under the umbrella of a WRONG PID error that are significant to explicitly identify. When these errors occur, the *XactErr* status bit in the queue head is set and the *CErr* field is decremented. When the *PIDCode* indicates a SETUP, the following responses are protocol errors and result in *XactErr* bit being set to a one and the *CErr* field being decremented.

- *EPS* field indicates a high-speed device and it returns a Nak handshake to a SETUP.
- *EPS* field indicates a high-speed device and it returns a Nyet handshake to a SETUP.
- *EPS* field indicates a low- or full-speed device and the complete-split receives a Nak handshake.

**Table 41-53. Summary of Transaction Errors**

Event / Result	Queue Head/qTD/iTD/siTD Side-effects		USB Status Register (USBSTS)
	Cerr	Status Field	USBERRINT
CRC	-1	XactErr set to a one.	1 <sup>1</sup>
Timeout	-1	XactErr set to a one.	1 <sup>1</sup>
Bad PID <sup>2</sup>	-1	XactErr set to a one.	1 <sup>1</sup>
Babble	N/A	Section <a href="#">Serial Bus Babble</a>	1
Buffer Error	N/A	Section <a href="#">Data Buffer Error</a>	

1. If occurs in a queue head, then *USBERRINT* is asserted only when *CErr* counts down from a one to a zero. In addition the queue is halted, see [Halting a Queue Head](#).
2. The host controller received a response from the device, but it could not recognize the PID as a valid PID.

### 41.5.3.15.1.2 Serial Bus Babble

When a device transmits more data on the USB than the host controller is expecting for this transaction, it is defined to be babbling. In general, this is called a *Packet Babble*.

When a device sends more data than the *Maximum Length* number of bytes, the host controller sets the *Babble Detected* bit to a one and halts the endpoint if it is using a queue head (see [Halting a Queue Head](#)). *Maximum Length* is defined as the minimum of *Total Bytes to Transfer* and *Maximum Packet Size*. The *CErr* field is not decremented for a packet babble condition (only applies to queue heads). A babble condition also exists if IN transaction is in progress at High-speed EOF2 point. This is called a frame babble. A frame babble condition is recorded into the appropriate schedule data structure. In addition, the host controller must disable the port to which the frame babble is detected.

The *USBERRINT* bit in the *USB\_n\_USBSTS* register is set to a one and if the *USB Error Interrupt Enable* bit in the *USB\_n\_USBINTR* register is a one, then a hardware interrupt is signaled to the system at the next interrupt threshold. The host controller must never start an OUT transaction that will babble across a micro-frame EOF.

#### NOTE

When a host controller detects a data PID mismatch, it must either: disable the packet babble checking for the duration of the bus transaction or do packet babble checking based solely on *Maximum Packet Size*. The USB core specification defines the requirements on a data receiver when it receives a data PID mismatch (for example, expects a DATA0 and gets a DATA1 or visa-versa). In summary, it must ignore the received data and respond with an ACK handshake, in order to advance the transmitter's data sequence.

The EHCI interface allows System software to provide buffers for a Control, Bulk or Interrupt IN endpoint that are not an even multiple of the maximum packet size specified by the device. Whenever a device misses an ACK for an IN endpoint, the host and device are out of synchronization with respect to the progress of the data transfer. The host controller may have advanced the transfer to a buffer that is less than maximum packet size. The device will re-send its maximum packet size data packet, with the original data PID, in response to the next IN token. In order to properly manage the bus protocol, the host controller must disable the packet babble check when it observes the data PID mismatch.

#### 41.5.3.15.1.3 Data Buffer Error

This event indicates that an overrun of incoming data or a underrun of outgoing data has occurred for this transaction.

This would generally be caused by the host controller not being able to access required data buffers in memory within necessary latency requirements. These conditions are not considered transaction errors, and do not effect the error count in the queue head. When these errors do occur, the host controller records the fact the error occurred by setting the *Data Buffer Error* bit in the queue head, iTD or siTD.

If the data buffer error occurs on a non-isochronous IN, the host controller will not issue a handshake to the endpoint. This will force the endpoint to resend the same data (and data toggle) in response to the next IN to the endpoint.

If the data buffer error occurs on an OUT, the host controller must corrupt the end of the packet so that it cannot be interpreted by the device as a good data packet. Simply truncating the packet is not considered acceptable. An acceptable implementation option is to 1's complement the CRC bytes and send them. There are other options suggested in the Transaction Translator section of the USB Specification Revision 2.0.

#### 41.5.3.15.1.4 USB Interrupt (Interrupt on Completion (IOC))

Transfer Descriptors (iTDS, siTDs, and queue heads (qTDs)) contain a bit that can be set to cause an interrupt on their completion. The completion of the transfer associated with that schedule item causes the USB Interrupt (USBINT) bit in the USB\_n\_USBSTS register to be set to a one.

In addition, if a short packet is encountered on an IN transaction associated with a queue head, then this event also causes USBINT to be set to a one. If the USB Interrupt Enable bit in the USB\_n\_USBINTR register is set to a one, a hardware interrupt is signaled to the system at the next interrupt threshold. If the completion is because of errors, the *USBERRINT* bit in the USB\_n\_USBSTS register is also set to a one.

#### 41.5.3.15.1.5 Short Packet

Reception of a data packet that is less than the endpoint's Max Packet size during Control, Bulk or Interrupt transfers signals the completion of the transfer. Whenever a short packet completion occurs during a queue head execution, the *USBINT* bit in the USB\_n\_USBSTS register is set to a one.

If the *USB Interrupt Enable* bit is set in the USB\_n\_USBINTR register, a hardware interrupt is signaled to the system at the next interrupt threshold.

### 41.5.3.15.2 Host Controller Event Interrupts

These interrupt sources are independent of the interrupt threshold (with the one exception being the Interrupt on Async Advance, see Section [Interrupt on Async Advance](#) ).

#### 41.5.3.15.2.1 Port Change Events

Port registers contain status and status change bits. When the status change bits are set to a one, the host controller sets the *Port Change Detect* bit in the USBSTS register to a one.

If the *Port Change Interrupt Enable* bit in the USB\_n\_USBINTR register is a one, then the host controller will issue a hardware interrupt. The port status change bits include:

- Connect Status Change
- Port Enable/Disable Change
- Over-current Change
- Force Port Resume

#### 41.5.3.15.2.2 Frame List Rollover

This event indicates that the host controller has wrapped the frame list. The current programmed size of the frame list effects how often this interrupt occurs.

If the frame list size is 1024, then the interrupt will occur every 1024 milliseconds, if it is 512, then it will occur every 512 milliseconds, etc. When a frame list rollover is detected, the host controller sets the *Frame List Rollover* bit in the USB.USBSTS register to a one. If the *Frame List Rollover Enable* bit in the USB.USBINTR register is set to a one, the host controller issues a hardware interrupt. This interrupt is not delayed to the next interrupt threshold.

#### 41.5.3.15.2.3 Interrupt on Async Advance

This event is used for deterministic removal of queue heads from the asynchronous schedule. Whenever the host controller advances the on-chip context of the asynchronous schedule, it evaluates the value of the *Interrupt on Async Advance Doorbell* bit in the USB.USBCMD register.

If it is a one, it sets the *Interrupt on Async Advance* bit in the USB.USBSTS register to a one. If the *Interrupt on Async Advance Enable* bit in the USB.USBINTR register is a one, the host controller issues a hardware interrupt at the next interrupt threshold. A detailed explanation of this feature is described in Section [Removing Queue Heads from Asynchronous Schedule](#) .

### 41.5.3.15.2.4 Host System Error

The host controller is a bus master and any interaction between the host controller and the system may experience errors.

The type of host error may be catastrophic to the host controller (such as a Master Abort) making it impossible for the host controller to continue in a coherent fashion. In the presence of non-catastrophic host errors, such as parity errors, the host controller could potentially continue operation. The recommended behavior for these types of errors is to escalate it to a catastrophic error and halt the host controller. Host-based error must result in the following actions:

- The *Run/Stop* bit in the USB.USBCMD register is set to a zero.
- The following bits in the USB.USBSTS register are set:
  - *Host System Error* bit is to a one.
  - *HCHalted* bit is set to a one.
- If the *Host System Error Enable* bit in the USB.USBINTR register is a one, then the host controller will issue a hardware interrupt. This interrupt is not delayed to the next interrupt threshold. The following table summarizes the required actions taken on the various host errors.

**Table 41-54. Summary Behavior of EHCI Host Controller on Host System Errors**

Cycle Type	Master Abort	Target Abort	Data Phase Parity
Frame list pointer fetch (read)	Fatal	Fatal	Fatal [o]
siTD fetch (read)	Fatal	Fatal	Fatal [o]
siTD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
iTD fetch (read)	Fatal	Fatal	Fatal [o]
iTD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
qTD fetch (read)	Fatal	Fatal	Fatal [o]
qHD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
Data write	Fatal [o]	Fatal [o]	Fatal [o]
Data read	Fatal	Fatal	Fatal [o]

Potentially, a host controller implementation could continue operation without a halt. However, the recommended behavior is to halt the host controller.

#### NOTE

After a *Host System Error*, Software must reset the host controller through *HCRreset* in the USB.USBCMD register before re-initializing and restarting the host controller.

## 41.5.4 EHCI Deviation

For the purposes a dual-role Host/Device controller with support for On-The-Go applications, it is necessary to deviate from the EHCI specification. Enhanced Host Controller Interface Specification for Universal Serial Bus, Revision 0.95, November 2000, Intel Corporation. <http://www.intel.com>. Device operation & On-The-Go operation is not specified in the EHCI and thus the implementation supported in this core is proprietary.

The host mode operation of the core is near EHCI compatible with few minor differences documented in this section.

The particulars of the deviations occur in the areas summarized here:

- Embedded Transaction Translator - Allows direct attachment of FS and LS devices in host mode without the need for a companion controller.
- Device operation - In host mode the device operational registers are generally disabled and thus device mode is mostly transparent when in host mode. However, there are a couple exceptions documented in the following sections.
- Embedded design interface - This core does not have a PCI Interface and therefore the PCI configuration registers described in the EHCI specification are not applicable.
- On-The-Go Operation - This design includes an On-The-Go controller for Port #1.

### 41.5.4.1 Embedded Transaction Translator Function

The OTG controller supports directly connected full and low speed devices without requiring a companion controller by including the capabilities of a USB 2.0 high speed hub transaction translator.

Although there is no separate Transaction Translator block in the system, the transaction translator function normally associated with a high speed hub has been implemented within the DMA and Protocol engine blocks. The embedded transaction translator function is an extension to EHCI interface, but makes use of the standard data structures and operational models that exist in the EHCI specification to support full and low speed devices.

#### 41.5.4.1.1 Capability Registers

The following additions have been added to the capability registers to support the embedded Transaction Translator Function:

- N\_TT added to USB.HCSPARAMS - Host Control Structural Parameters
- N\_PTT added to USB.HCSPARAMS - Host Control Structural Parameters

### 41.5.4.1.2 Operational Registers

The following additions have been added to the operational registers to support the embedded TT:

- Addition of two-bit Port Speed (PSPD) to the [Port Status & Control \(USB\\_nPORTSC1\)](#) register.

### 41.5.4.1.3 Discovery-EHCI Deviation

In a standard EHCI controller design, the EHCI host controller driver detects a Full speed (FS) or Low speed (LS) device by noting if the port enable bit is set after the port reset operation.

The port enable will only be set in a standard EHCI controller implementation after the port reset operation and when the host and device negotiate a High-Speed connection (that is, Chirp completes successfully).

Because this controller has an embedded Transaction Translator, the port enable will always be set after the port reset operation regardless of the result of the host device chirp result and the resulting port speed will be indicated by the PSPD field in USB.PORTSCx.

Therefore, the standard EHCI host controller driver requires an alteration to handle directly connected Full and Low speed devices or hubs.

The change is a fundamental one in that is summarized in the following table.

**Table 41-55. Summary of EHCI**

Standard EHCI	EHCI with embedded Transaction Translator
After port enable bit is set following a connection and reset sequence, the device/hub is assumed to be HS.	After port enable bit is set following a connection and reset sequence, the device/hub speed is noted from USB.PORTSCx.
FS and LS devices are assumed to be downstream from a HS hub thus, all port-level control is performed through the Hub Class to the nearest Hub.	FS and LS device can be either downstream from a HS hub or directly attached. When the FS/LS device is downstream from a HS hub, then port-level control is done using the Hub Class through the nearest Hub. When a FS/LS device is directly attached, then port-level control is accomplished using USB.PORTSCx.
FS and LS devices are assumed to be downstream from a HS hub with HubAddr=X. [where HubAddr > 0 and HubAddr is the address of the Hub where the bus transitions from HS to FS/LS (ie. Split target hub)]	FS and LS device can be either downstream from a HS hub with HubAddr = X [HubAddr > 0] or directly attached [where HubAddr = 0 and HubAddr is the address of the Root Hub where the bus transitions from HS to FS/LS (ie. Split target hub is the root hub) ]

#### 41.5.4.1.4 Data Structures

The same data structures used for FS/LS transactions through a HS hub are also used for transactions through the Root Hub with sm embedded Transaction Translator.

Here it is demonstrated how the Hub Address and Endpoint Speed fields should be set for directly attached FS/LS devices and hubs:

1. QH (for direct attach FS/LS) - Async. (Bulk/Control Endpoints) Periodic (Interrupt)
  - Hub Address = 0
  - Transactions to direct attached device/hub.
    - QH.EPS = Port Speed
  - Transactions to a device downstream from direct attached FS hub.
    - QH.EPS = Downstream Device Speed

#### NOTE

When QH.EPS = 01 (LS) and PORTSCx.PSPD = 00 (FS), a LS-pre-pid will be sent before the transmitting LS traffic.

Maximum Packet Size must be less than or equal 64 or undefined behaviour may result.

2. siTD (for direct attach FS) - Periodic (ISO Endpoint)
  - All FS ISO transactions:
    - Hub Address = 0
    - siTD.EPS = 00 (full speed)
      - Maximum Packet Size must less than or equal to 1023 or undefined behaviour may result.

#### 41.5.4.1.5 Operational Model

The operational models are well defined for the behavior of the Transaction Translator (see USB 2.0 specification. Universal Serial Bus Specification, Revision 2.0, April 2000, Compaq, Hewlett-Packard, Intel, Lucent, Microsoft, NEC, Philips. <http://www.usb.org>) and for the EHCI controller moving packets between system memory and a USB-HS hub. Because the embedded Transaction Translator exists within the host controller there is no physical bus between EHCI host controller driver and the USB FS/LS bus. These sections will briefly discuss the operational model for how the EHCI and Transaction Translator operational models are combined without the physical bus between. The following sections assume the reader is familiar with both the EHCI and USB 2.0 Transaction Translator operational models.

#### 41.5.4.1.5.1 Micro- frame Pipeline

The EHCI operational model uses the concept of H-frames and B-frames to describe the pipeline between the Host (H) and the Bus (B). The embedded Transaction Translator shall use the same pipeline algorithms specified in the USB 2.0 specification for a Hub-based Transaction Translator.

All periodic transfers always begin at B-frame 0 (after SOF) and continue until the stored periodic transfers are complete. As an example of the micro-frame pipeline implemented in the embedded Transaction Translator, all periodic transfers that are tagged in EHCI to execute in H-frame 0 will be ready to execute on the bus in B-frame 0.

It is important to note that when programming the S-mask and C-masks in the EHCI data structures to schedule periodic transfers for the embedded Transaction Translator, the EHCI host controller driver must follow the same rules specified in EHCI for programming the S-mask and C-mask for downstream Hub-based Transaction Translators.

Once periodic transfers are exhausted, any stored asynchronous transfer will be moved. Asynchronous transfers are opportunistic in that they shall execute whenever possible and their operation is not tied to H-frame and B-frame boundaries with the exception that an asynchronous transfer can not babble through the SOF (start of B-frame 0.)

#### 41.5.4.1.5.2 Split State Machines

The start and complete split operational model differs from EHCI slightly because there is no bus medium between the EHCI controller and the embedded Transaction Translator.

Where a start or complete-split operation would occur by requesting the split to the HS hub, the start/complete split operation is simple an internal operation to the embedded Transaction Translator. The following table summarizes the conditions where handshakes are emulated from internal state instead of actual handshakes to HS split bus traffic.

**Table 41-56. Summary of the Conditions of Handshakes<sup>1</sup>**

Condition	Emulate TT Response
Start-Split: All asynchronous buffers full.	NAK
Start-Split: All periodic buffers full.	ERR
Start-Split: Success for start of Async. Transaction.	ACK
Start-Split: Start Periodic Transaction.	No Handshake (Ok)
Complete-Split: Failed to find transaction in queue.	Bus Time Out
Complete-Split: Transaction in Queue is Busy.	NYET
Complete-Split: Transaction in Queue is Complete.	[Actual Handshake from LS/FS device]

1. The un-shaded cells represent Start-Splits and the shaded cells represent Complete-Splits

#### 41.5.4.1.5.3 Asynchronous Transaction Scheduling and Buffer Management

The following USB 2.0 specification items are implemented in the embedded Transaction Translator:

- Sequencing is provided & a packet length estimator ensures no full-speed/low-speed packet babbles into SOF time.
- Transaction tracking for 2 data pipes.

##### 41.5.4.1.5.3.1 USB 2.0 - 11.17.3

- Sequencing is provided & a packet length estimator ensures no full-speed/low-speed packet babbles into SOF time.

##### 41.5.4.1.5.3.2 USB 2.0 - 11.17.4

- Transaction tracking for 2 data pipes.

#### 41.5.4.1.5.4 Periodic Transaction Scheduling and Buffer Management

The following USB 2.0 specification items are implemented in the embedded Transaction Translator:

- Abort of pending start-splits
  - EOF (and not started in micro-frames 6)
  - Idle for more than 4 micro-frames
- Abort of pending complete-splits
  - EOF
  - Idle for more than 4 micro-frames
- Transaction tracking for up to 16 data pipes.
- Complete-split transaction searching.

#### NOTE

There is no data schedule mechanism for these transactions other than the micro-frame pipeline. The embedded TT assumes the number of packets scheduled in a frame does not exceed the frame duration (1 ms) or else undefined behavior may result.

##### 41.5.4.1.5.4.1 USB 2.0 - 11.18.6.[1-2]

- Abort of pending start-splits
  - EOF (and not started in micro-frames 6)
  - Idle for more than 4 micro-frames
- Abort of pending complete-splits

- EOF
- Idle for more than 4 micro-frames

### 41.5.4.1.5.4.2 USB 2.0 - 11.18.[7-8]

- Transaction tracking for up to 16 data pipes.
- Complete-split transaction searching.

#### NOTE

There is no data schedule mechanism for these transactions other than the micro-frame pipeline. The embedded TT assumes the number of packets scheduled in a frame does not exceed the frame duration (1 ms) or else undefined behavior may result.

### 41.5.4.1.5.5 Multiple Transaction Translators

The maximum number of embedded Transaction Translators that is currently supported is one as indicated by the N\_TT field in the [Host Controller Structural Parameters \(USB\\_nHCSPARAMS\)](#) register.

## 41.5.4.2 Device Operation

The co-existence of a device operational controller within the host controller has little effect on EHCI compatibility for host operation except as noted in this section.

### 41.5.4.2.1 USB\_USBMODE Register

Given that the dual-role controller is initialized in neither host nor device mode, the [USB Device Mode \(USB\\_nUSBMODE\)](#) register must be programmed for host operation before the EHCI host controller driver can begin EHCI host operations.

### 41.5.4.2.2 Non-Zero Fields the Register File

Some of the reserved fields and reserved addresses in the capability registers and operational register have use in device mode, the following must be adhered to:

- Write operations to all EHCI reserved fields (some of which are device fields) with the operation registers should always be written to zero. This is an EHCI requirement of the device controller driver that must be adhered to.
- Read operations by the host controller must properly mask EHCI reserved fields (some of which are device fields) because fields that are used exclusive for device are undefined in host mode .

### 41.5.4.2.3 SOF Interrupt

This SOF Interrupt used for device mode is shared as a free running 125us interrupt for host mode.

EHCI does not specify this interrupt but it has been added for convenience and as a potential software time base. See [USB Status Register \(USB\\_nUSBSTS\)](#) and [Interrupt Enable Register \(USB\\_nUSBINTR\)](#) registers.

### 41.5.4.3 Embedded Design Interface

This is an Embedded USB Host Controller as defined by the EHCI specification and thus does not implement the PCI configuration registers.

#### 41.5.4.3.1 Frame Adjust Register

Given that the optional PCI configuration registers are not included in this implementation, there is no corresponding bit level timing adjustments like is provided by the Frame Adjust register in the PCI configuration registers. Starts of micro-frames are timed precisely to 125 us using the transceiver clock as a reference clock. That is, a 60 Mhz transceiver clock for 8-bit physical interfaces & full-speed serial interfaces or 30 Mhz transceiver clock for 16-bit physical interfaces.

### 41.5.4.4 Miscellaneous variations from EHCI

#### 41.5.4.4.1 Programmable Physical Interface Behaviour

This design supports multiple Physical interfaces which can operate in differing modes when the core is configured with software programmable Physical Interface Modes. Software programmability allows the selection of the Physical interface part during the board design phase instead of during the chip design phase. The control bits for selecting the Physical Interface operating mode have been added to the [Port Status & Control \(USB\\_nPORTSC1\)](#) register providing a capability that is not defined by EHCI.

#### 41.5.4.4.2 Discovery

#### 41.5.4.4.2.1 Port Reset

The port connect methods specified by EHCI require setting the port reset bit in the [Port Status & Control \(USB\\_nPORTSC1\)](#) register for a duration of 10ms. Due to the complexity required to support the attachment of devices that are not high speed there are counter already present in the design that can count the 10ms reset pulse to alleviate the requirement of the software to measure this duration. Therefore, the basic connection is then summarized as the following:

- [Port Change Interrupt] Port connect change occurs to notify the host controller driver that a device has attached.
- Software shall write a '1' to reset the device.
- Software shall write a '0' to reset the device after 10 ms.
  - This step, which is necessary in a standard EHCI design, may be omitted with this implementation. Should the EHCI host controller driver attempt to write a '0' to the reset bit while a reset is in progress, the write will simple be ignored and the reset will continue until completion.
- [Port Change Interrupt] Port enable change occurs to notify the host controller that the device is now operational and at this point the port speed has been determined.

#### 41.5.4.4.2.2 Port Speed Detection

After the port change interrupt indicates that a port is enabled, the EHCI stack should determine the port speed. Unlike the EHCI implementation, which will re-assign the port owner for any device that does not connect at High-Speed, this host controller supports direct attach of non High-Speed devices.

Therefore, the following differences are important regarding port speed detection:

- Port Owner is read-only and always reads 0.
- A 2-bit Port Speed indicator has been added to PORTSC to provide the current operating speed of the port to the host controller driver.
- A 1-bit High Speed indicator has been added to PORTSC to signify that the port is in High-Speed vs. Full/Low Speed - *This information is redundant with the 2-bit Port Speed indicator above.*

#### 41.5.4.4.3 Port Test Mode

Port Test Control mode behaves fully as described in EHCI. An alternate host controller driver procedure is not necessary or supported.

## 41.5.5 Device Data Structures

This section defines the interface data structures used to communicate control, status, and data between Device Controller Driver (DCD) Software and the Device Controller.

The data structure definitions in this chapter support a 32-bit memory buffer address space. The interface consists of device Queue Heads and Transfer Descriptors.

### NOTE

Software must ensure that no interface data structure reachable by the Device Controller spans a 4K-page boundary.

The data structures defined in the chapter are (from the device controller's perspective) a mix of read-only and read/ writable fields. The device controller must preserve the read-only fields on all data structure writes.

The figure below shows the organization of the EndPoint Queue Head.

**Figure 41-27. EndPoint Queue Head Organization**

Endpoint queue heads are arranged in an array in a continuous area of memory pointed to by the USB.ENDPOINTLISTADDR pointer. The even -numbered device queue heads in the list support receive endpoints (OUT/SETUP) and the odd-numbered queue heads in the list are used for transmit endpoints (IN/INTERRUPT). The device controller will index into this array based upon the endpoint number received from the USB bus. All information necessary to respond to transactions for all primed transfers is contained in this list so the Device Controller can readily respond to incoming requests without having to traverse a linked list.

**NOTE**

The Endpoint Queue Head List must be aligned to a 2k boundary.

**41.5.5.1 Endpoint Queue Head (dQH)**

The device Endpoint Queue Head (dQH) is where all transfers for a given endpoint are managed. The dQH is a 48-byte data structure, but must be aligned on 64-byte boundaries.

During priming of an endpoint, the dTD (device transfer descriptor) is copied into the overlay area of the dQH, which starts at the nextTD pointer DWord and continues through the end of the buffer pointers DWords. After a transfer is complete, the dTD status DWord is updated in the dTD pointed to by the currentTD pointer. While a packet is in progress, the overlay area of the dQH is used as a staging area for the dTD so that the Device Controller can access needed information with little minimal latency.

**Table 41-57. Endpoint Queue Head (dQH)**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Host Controller Read/Write

Host Controller Read Only

### 41.5.5.1.1 Endpoint Capabilities/Characteristics

This DWord specifies static information about the endpoint, in other words, this information does not change over the lifetime of the endpoint. Device Controller software should not attempt to modify this information while the corresponding endpoint is enabled.

Table 41-58 describes the endpoint capabilities.

**Table 41-58. Endpoint Capabilities/Characteristics**

Bit	Description
31-30	Mult. This field is used to indicate the number of packets executed per transaction description as given by the following:  00 - Execute N Transactions as demonstrated by the USB variable length packet protocol where N is computed using the Maximum Packet Length (dQH) and the Total Bytes field (dTD)  01 Execute 1 Transaction. 10 Execute 2 Transactions. 11 Execute 3 Transactions.  <b>NOTE:</b> Non-ISO endpoints must set Mult="00". ISO endpoints must set Mult="01", "10", or "11" as needed.
29	Zero Length Termination Select. This bit is used to indicate when a zero length packet is used to terminate transfers where the total transfer length is a multiple of the Maximum Packet Length. This bit is not relevant for Isochronous  0 - Enable zero length packet to terminate transfers equal to a multiple of the Maximum Packet Length. (default).  1 - Disable the zero length packet on transfers that are equal in length to a multiple Maximum Packet Length.
28-27	Reserved. These bits reserved for future use and should be set to zero.
26-16	Maximum Packet Length. This directly corresponds to the maximum packet size of the associated endpoint (wMaxPacketSize). The maximum value this field may contain is 0x400 (1024).
15	Interrupt On Setup (IOS). This bit is used on control type endpoints to indicate if USBINT is set in response to a setup being received.
14-0	Reserved. Bits reserved for future use and should be set to zero.

### 41.5.5.1.2 Transfer Overlay-Endpoint Queue Head

The seven DWords in the overlay area represent a transaction working space for the device controller.

The general operational model is that the device controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, then it will not read the associated endpoint.

After an endpoint is readied, the dTD will be copied into this queue head overlay area by the device controller. Until a transfer is expired, software must not write the queue head overlay area or the associated transfer descriptor. When the transfer is complete, the device controller will write the results back to the original transfer descriptor and advance the queue.

See dTD for a description of the overlay fields.

### 41.5.5.1.3 Current dTD Pointer

The current dTD pointer is used by the device controller to locate the transfer in progress. This word is for Device Controller (hardware) use only and should not be modified by DCD software.

The following table describes the dTD Pointer.

**Table 41-59. Next dTD Pointer**

Bit	Description
31-5	Current dTD. This field is a pointer to the dTD that is represented in the transfer overlay area. This field will be modified by the Device Controller to next dTD pointer during endpoint priming or queue advance.
4-0	Reserved. Bit reserved for future use and should be set to zero.

### 41.5.5.1.4 Set-up Buffer

The set-up buffer is dedicated storage for the 8-byte data that follows a set-up PID.

**NOTE**

Each endpoint has a TX and an RX dQH associated with it, and only the RX queue head is used for receiving setup data packets.

The following table describes the Multiple Mode Control.

**Table 41-60. Multiple Mode Control (HCCPARAMS)**

DWord	Bits	Description
1	31-0	Setup Buffer 0. This buffer contains bytes 3 to 0 of an incoming setup buffer packet and is written by the device controller to be read by software.
2	31-0	Setup Buffer 1. This buffer contains bytes 7 to 4 of an incoming setup buffer packet and is written by the device controller to be read by software.

## 41.5.5.2 Endpoint Transfer Descriptor (dTD)

The dTD describes to the device controller the location and quantity of data to be sent/received for a given transfer.

The DCD should not attempt to modify any field in an active dTD except the Next Like Pointer, which should only be modified as described in section [Managing Transfers with Transfer Descriptors](#).

Table below shows the Endpoint Transfer Descriptor (dTDT).

**Table 41-61. Endpoint Transfer Descriptor (dTDT)**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Next Link Pointer																												0	T		
0	Total Bytes															ioc	0	MultO	0	Status											
Buffer Pointer (Page 0)														Current Offset																	
Buffer Pointer (Page 1)														0	Frame Number																
Buffer Pointer (Page 2)														Reserved																	
Buffer Pointer (Page 3)														Reserved																	
Buffer Pointer (Page 4)														Reserved																	

Host Controller Read/Write

Host Controller Read Only

The following table describes the dTD Pointer.

**Table 41-62. Next dTD Pointer**

Bit	Description
31-5	Next Transfer Element Pointer. This field contains the physical memory address of the next dTD to be processed. The field corresponds to memory address signals [31:5], respectively.
4-1	Reserved. Bits reserved for future use and should be set to zero.
0	Terminate (T). 1=pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Device Controller that there are no more valid entries in the queue.

The following table describes the dTD Token.

**Table 41-63. dTD Token**

Bit	Description
31	Reserved. Bit reserved for future use and should be set to zero.
30-16	<p>Total Bytes. This field specifies the total number of bytes to be moved with this transfer descriptor. This field is decremented by the number of bytes actually moved during the transaction and only on the successful completion of the transaction.</p> <p>The maximum value software may store in the field is 5*4K (5000H). This is the maximum number of bytes 5 page pointers can access. Although it is possible to create a transfer up to 20K this assumes the 1<sup>st</sup> offset into the first page is 0. When the offset cannot be predetermined, crossing past the 5th page can be guaranteed by limiting the total bytes to 16K**. Therefore, the maximum recommended transfer is 16K (4000H).</p> <p>If the value of the field is zero when the host controller fetches this transfer descriptor (and the active bit is set), the device controller executes a zero-length transaction and retires the transfer descriptor.</p>

*Table continues on the next page...*

**Table 41-63. dTD Token (continued)**

	It is not a requirement for IN transfers that Total Bytes To Transfer be an even multiple of <i>Maximum Packet Length</i> . If software builds such a transfer descriptor for an IN transfer, the last transaction will always be less than <i>Maximum Packet Length</i> .
15	Interrupt On Complete (IOC). This bit is used to indicate if USBINT is to be set in response to device controller being finished with this dTD.
14-12	Reserved. Bits reserved for future use and should be set to zero.
11-10	Multiplier Override (MultiO). This field can be used for transmit ISO's (ie. ISO-IN) to override the multiplier in the QH. This field must be zero for all packet types that are not transmit-ISO. Example: if QH.multiplier = 3; Maximum packet size = 8; Total Bytes = 15; MultiO = 0 [default] Three packets are sent: {Data2(8); Data1(7); Data0(0)} if QH.multiplier = 3; Maximum packet size = 8; Total Bytes = 15; MultiO = 2 Two packets are sent: {Data1(8); Data0(7)} For maximal efficiency, software should compute MultiO = greatest integer of (Total Bytes / Max. Packet Size) except for the case when Total Bytes = 0; then MultiO should be 1. Note: Non-ISO and Non-TX endpoints must set MultiO = "00".
9-8	Reserved. Bits reserved for future use and should be set to zero.
7-0	Status. This field is used by the Device Controller to communicate individual command execution states back to the Device Controller software. This field contains the status of the last transaction performed on this qTD. The bit encodings are: Bit Status Field Description 7 Active. 6 Halted. 5 Data Buffer Error. 3 Transaction Error. 4, 2, 0 Reserved.

The table below describes the dTD Buffer Page Pointer List.

**Table 41-64. dTD Buffer Page Pointer List**

Bit	Description
31-12	Buffer Pointer. Selects the page offset in memory for the packet buffer. Non virtual memory systems will typically set the buffer pointers to a series of incrementing integers.
0,11-0	Current Offset. Offset into the 4kb buffer where the packet is to begin.
1,10-0	Frame Number. Written by the device controller to indicate the frame number in which a packet finishes. This is typically be used to correlate relative completion times of packets on an ISO endpoint.

### 41.5.6 Device Operational Model

The function of the device operation is to transfer a request in the memory image to and from the Universal Serial Bus.

Using a set of linked list transfer descriptors, pointed to by a queue head, the device controller will perform the data transfers. The following sections explain the use of the device controller from the device controller driver (DCD) point-of-view and further describe how specific USB bus events relate to status changes in the device controller programmer's interface.

### 41.5.6.1 Device Controller Initialization

After hardware reset, the device is disabled until the Run/Stop bit is set to a '1'. In the disabled state, the pull-up on the USB D+ is not active which prevents an attach event from occurring. At a minimum, it is necessary to have the queue heads setup for endpoint zero before the device attach occurs.

Shortly after the device is enabled, a USB reset will occur followed by setup packet arriving at endpoint 0. A Queue head must be prepared so that the device controller can store the incoming setup packet.

In order to initialize a device, the software should perform the following steps:

- Set Controller Mode in the USB.USBMODE register to device mode.

#### NOTE

Transitioning from host mode to device mode requires a device controller reset before modifying USB.USBMODE.

- Allocate and Initialize device queue heads in system memory.
  - Minimum: Initialize device queue heads 0 Tx & 0 Rx.

#### NOTE

All device queue heads for control endpoints must be initialized before the endpoint is enabled. Non-Control device queue heads before the endpoint can be used.

- For information on device queue heads, refer to section [Device Data Structures](#).
- Configure USB.ENDPOINTLISTADDR Pointer.
  - For additional information on USB.ENDPOINTLISTADDR, refer to the register table.
- Enable the microprocessor interrupt associated with the USB core.
  - Recommended: enable all device interrupts including: USBINT, USBERRINT, Port Change Detect, USB Reset Received, DCSuspend.
  - For a list of available interrupts refer to the [Interrupt Enable Register \(USB\\_nUSBINTR\)](#) and the [USB Status Register \(USB\\_nUSBSTS\)](#) register tables.
- Set Run/Stop bit to Run Mode.

- After the Run bit is set and the device is connected to a host, a Bus Reset will be issued by host downstream port. The DCD must monitor the reset event and adjust the software state as described in the Bus Reset section of the Port State and Control section below.

### NOTE

Endpoint 0 is designed as a control endpoint only and does not need to be configured using ENDPTCTRL0 register.

It is also not necessary to prime Endpoint 0 initially because the first packet received will always be a setup packet. The contents of the first setup packet will require a response in accordance with USB device framework (Chapter 9) command set.

### 41.5.6.2 Port State and Control

From a chip or system reset, the device controller enters the *powered* state. A transition from the *powered* state to the *attach* state occurs when the Run/Stop bit is set to a '1'.

After receiving a reset on the bus, the port will enter the *defaultFS* or *defaultHS* state in accordance with the reset protocol described in Appendix C.2 of the USB Specification Rev. 2.0.

The following state diagram depicts the state of a USB 2.0 device.

**Figure 41-28. Device State Diagram**

States *powered*, *attach*, *defaultFS/HS*, *suspendFS/HS* are implemented in the device controller and are communicated to the DCD using the following status bits:

The following table describes the Device Controller State Information Bits.

**Table 41-65. Device Controller State Information Bits**

Bit	Register
DCSuspend	USB Status Register (USB_nUSBSTS)
USB Reset Received	USB Status Register (USB_nUSBSTS)
Port Change Detect	USB Status Register (USB_nUSBSTS)
High-Speed Port	Port Status & Control (USB_nPORTSC1)

It is the responsibility of the DCD to maintain a state variable to differentiate between the *DefaultFS/HS* state and the *Address/Configured* states. Change of state from *Default* to *Address* and the *Configured* states is part of the enumeration process described in the device framework section of the USB 2.0 Specification.

As a result of entering the *Address* state, the device address register (DEVICEADDR) must be programmed by the DCD.

Entry into the *Configured* indicates that all endpoints to be used in the operation of the device have been properly initialized by programming the USB\_UOG\_ENDPTCTRLx registers and initializing the associated queue heads.

#### 41.5.6.2.1 Bus Reset

A bus reset is used by the host to initialize downstream devices.

When a bus reset is detected, the device controller will renegotiate its attachment speed, reset the device address to 0, and notify the DCD by interrupt (assuming the USB Reset Interrupt Enable is set). After a reset is received, all endpoints (except endpoint 0) are disabled and any primed transactions will be cancelled by the device controller. The concept of priming will be clarified below, but the DCD must perform the following tasks when a reset is received:

Clear all setup token semaphores by reading the [Endpoint Status \(USB\\_nENDPTSTAT\)](#) register and writing the same value back to the [Endpoint Status \(USB\\_nENDPTSTAT\)](#) register.

Clear all the endpoint complete status bits by reading the [Endpoint Complete \(USB\\_nENDPTCOMPLETE\)](#) register and writing the same value back to the [Endpoint Complete \(USB\\_nENDPTCOMPLETE\)](#) register.

Cancel all primed status by waiting until all bits in the [Endpoint Prime \(USB\\_nENDPTPRIME\)](#) are 0 and then writing 0xFFFFFFFF to [Endpoint Flush \(USB\\_nENDPTFLUSH\)](#).

Read the reset bit in the [Port Status & Control \(USB\\_nPORTSC1\)](#) register and make sure that it is still active. A USB reset will occur for a minimum of 3 ms and the DCD must reach this point in the reset cleanup before end of the reset occurs, otherwise a hardware reset of the device controller is recommended (rare.)

- A hardware reset can be performed by writing a one to the device controller reset bit in the USBCMD reset. Note: a hardware reset will cause the device to detach from the bus by clearing the Run/Stop bit. Thus, the DCD must completely re-initialize the device controller after a hardware reset.

Free all allocated dTDs because they will no longer be executed by the device controller. If this is the first time the DCD is processing a USB reset event, then it is likely that no dTDs have been allocated.

At this time, the DCD may release control back to the OS because no further changes to the device controller are permitted until a Port Change Detect is indicated.

After a Port Change Detect, the device has reached the default state and the DCD can read the [Port Status & Control \(USB\\_nPORTSC1\)](#) to determine if the device is operating in FS or HS mode. At this time, the device controller has reached normal operating mode and DCD can begin enumeration according to the USB Chapter 9 - Device Framework.

### NOTE

The device DCD may use the FS/HS mode information to determine the bandwidth mode of the device

In some applications, it may not be possible to enable one or more pipes while in FS mode. *Beyond the data rate issue, there is no difference in DCD operation between FS and HS modes.*

## 41.5.6.2.2 Suspend/Resume

The details of suspend and resume are explained in these sections.

### 41.5.6.2.2.1 Suspend

#### Suspend Description

In order to conserve power, USB devices automatically enter the suspended state when the device has observed no bus traffic for a specified period. When suspended, the USB device maintains any internal status, including its address and configuration. Attached devices must be prepared to suspend at any time they are powered, regardless of if they have been assigned a non-default address, are configured, or neither. Bus activity may cease due to the host entering a suspend mode of its own. In addition, a USB device shall also enter the suspended state when the hub port it is attached to is disabled.

A USB device exits suspend mode when there is bus activity. A USB device may also request the host to exit suspend mode or selective suspend by using electrical signaling to indicate remote wakeup. The ability of a device to signal remote wakeup is optional. If the USB device is capable of remote wakeup signaling, the device must support the ability of the host to enable and disable this capability. When the device is reset, remote wakeup signaling must be disabled.

#### Suspend Operational Model

The device controller moves into the suspend state when suspend signaling is detected or activity is missing on the upstream port for more than a specific period. After the device controller enters the suspend state, the DCD is notified by an interrupt (assuming *DC Suspend Interrupt* is enabled). When the *DCSuspend* bit in the [Port Status & Control \(USB\\_nPORTSC1\)](#) is set to a '1', the device controller is suspended.

DCD response when the device controller is suspended is application specific and may involve switching to low power operation.

Information on the bus power limits in suspend state can be found in USB 2.0 specification.

### **NOTE**

Review system level clocking issues defined in section (Ref: Signals-Clocking) for the clocking requirements of a suspended device controller.

#### **41.5.6.2.2 Resume**

If the device controller is suspended, its operation is resumed when any non-idle signaling is received on its upstream facing port. In addition, the device can signal the system to resume operation by forcing resume signaling to the upstream port.

Resume signaling is sent upstream by writing a '1' to the Resume bit in the in the [Port Status & Control \(USB\\_nPORTSC1\)](#) while the device is in suspend state. Sending resume signal to an upstream port should cause the host to issue resume signaling and bring the suspended bus segment (one more devices) back to the active condition.

### **NOTE**

Before resume signaling can be used, the host must enable it by using the Set Feature command defined in device framework (chapter 9) of the USB 2.0 Specification.

#### **41.5.6.3 Managing Endpoints**

The USB 2.0 specification defines an endpoint, also called a device endpoint or an address endpoint as a uniquely addressable portion of a USB device that can source or sink data in a communications channel between the host and the device.

The endpoint address is specified by the combination of the endpoint number and the endpoint direction.

The channel between the host and an endpoint at a specific device represents a data pipe. Endpoint 0 for a device is always a *control* type data channel used for device discovery and enumeration. Other types of endpoints support by USB include *bulk*, *interrupt*, and *isochronous*. Each endpoint type has specific behavior related to packet response and error handling. More detail on endpoint operation can be found in the USB 2.0 specification.

The USB OTG device controller hardware supports up to 8 endpoint numbers.

Each endpoint direction is essentially independent and can be configured with differing behavior in each direction. For example, the DCD can configure endpoint 1-IN to be a bulk endpoint and endpoint 1-OUT to be an isochronous endpoint. This helps to conserve the total number of endpoints required for device operation. The only exception is that control endpoints must use both directions on a single endpoint number to function as a control endpoint. Endpoint 0 is, for example, is always a control endpoint and uses the pair of directions.

Each endpoint direction requires a *queue head* allocated in memory. To support the 8 endpoint numbers, 16 *queue heads* are required. The operation of an endpoint and use of *queue heads* are described later in this document.

#### 41.5.6.3.1 Endpoint Initialization

After hardware reset, all endpoints except endpoint zero are uninitialized and disabled. The DCD must configure and enable each endpoint by writing to configuration bit in the USB\_UOG\_ENDPTCTRLx register.

Each 32-bit USB\_UOG\_ENDPTCTRLx is split into an upper and lower half. The lower half of USB\_UOG\_ENDPTCTRLx is used to configure the receive or OUT endpoint and the upper half is likewise used to configure the corresponding transmit or IN endpoint. Control endpoints must be configured the same in both the upper and lower half of the USB\_UOG\_ENDPTCTRLx register otherwise the behavior is undefined. The following table shows how to construct a configuration word for endpoint initialization. The following table shows the fields and values for the Device Controller Endpoint initialization.

**Table 41-66. Device Controller Endpoint Initialization**

Field	Value
Data Toggle Reset	1
Data Toggle Inhibit	0
Endpoint Type	00 Control 01 Isochronous 10 Bulk

*Table continues on the next page...*

**Table 41-66. Device Controller Endpoint Initialization (continued)**

	11 Interrupt
Endpoint Stall	0

### 41.5.6.3.2 Stalling

There are two occasions where the device controller may need to return to the host a STALL.

The first occasion is the functional stall, which is a condition set by the DCD as described in the USB 2.0 device framework. A functional stall is only used on non-control endpoints and can be enabled in the device controller by setting the endpoint stall bit in the USB\_UOG\_ENDPTCTRLx register associated with the given endpoint and the given direction. In a functional stall condition, the device controller will continue to return STALL responses to all transactions occurring on the respective endpoint and direction until the endpoint stall bit is cleared by the DCD.

A protocol stall, unlike a function stall, is used on control endpoints is automatically cleared by the device controller at the start of a new control transaction (setup phase). When enabling a protocol stall, the DCD should enable the stall bits (both directions) as a pair. A single write to the USB\_UOG\_ENDPTCTRLx register can ensure that both stall bits are set at the same instant.

#### NOTE

Any write to the USB\_UOG\_ENDPTCTRLx register during operational mode must preserve the endpoint type field (that is, perform a read-modify-write).

The following table shows the response matrix for the Device Controller Stall.

**Table 41-67. Device Controller Stall Response Matrix**

USB Packet	Endpoint Stall Bit.	Effect on STALL bit.	USB Response
SETUP packet received by a non-control endpoint.	N/A	None.	STALL
IN/OUT/PING packet received by a non-control endpoint.	'1'	None.	STALL
IN/OUT/PING packet received by a non-control endpoint.	'0'	None.	ACK/ NAK/ NYET
SETUP packet received by a control endpoint.	N/A	Cleared	ACK
IN/OUT/PING packet received by a control endpoint	'1'	None	STALL

*Table continues on the next page...*

**Table 41-67. Device Controller Stall Response Matrix (continued)**

IN/OUT/PING packet received by a control endpoint.	'0'	None.	ACK/ NAK/ NYET
----------------------------------------------------	-----	-------	----------------------

### 41.5.6.3.3 Data Toggle

Data toggle is a mechanism to maintain data coherency between host and device for any given data pipe.

For more information on data toggle, refer to the USB 2.0 specification.

#### 41.5.6.3.3.1 Data Toggle Reset

The DCD may reset the data toggle state bit and cause the data toggle sequence to reset in the device controller by writing a '1' to the data toggle reset bit in the USB\_UOG\_ENDPTCTRLx register.

This should only be necessary when configuring/initializing an endpoint or returning from a STALL condition.

#### 41.5.6.3.3.2 Data Toggle Inhibit

#### NOTE

This feature is for test purposes only and should never be used during normal device controller operation.

Setting the *data toggle Inhibit bit* active ('1') causes the device controller to ignore the data toggle pattern that is normally sent and accept all incoming data packets regardless of the data toggle state.

In normal operation, the device controller checks the DATA0/DATA1 bit against the data toggle to determine if the packet is valid. If Data PID does not match the data toggle state bit maintained by the device controller for that endpoint, the Data toggle is considered not valid. If the data toggle is not valid, the device controller assumes the packet was already received and discards the packet (not reporting it to the DCD). To prevent the host controller from re-sending the same packet, the device controller will respond to the error packet by acknowledging it with either an ACK or NYET response.

#### 41.5.6.3.3.3 Priming Transmit Endpoints

Priming a transmit endpoint will cause the device controller to fetch the device transfer descriptor (dTd) for the transaction pointed to by the device queue head (dQH).

After the dTD is fetched, it will be stored in the dQH until the device controller completes the transfer described by the dTD. Storing the dTD in the dQH allows the device controller to fetch the operating context needed to handle a request from the host without the need to follow the linked list, starting at the dQH when the host request is received.

After the device has loaded the dTD, the leading data in the packet is stored in a FIFO in the device controller. This FIFO is split into virtual channels so that the leading data can be stored for any endpoint up to the maximum number of endpoints configured at device synthesis time.

After a priming request is complete, an endpoint state of primed is indicated in the USB\_UOG\_ENDPTSTATUS register. For a primed transmit endpoint, the device controller can respond to an IN request from the host and meet the stringent bus turnaround time of High Speed USB.

Because only the leading data is stored in the device controller FIFO, it is necessary for the device controller to begin filling in behind leading data after the transaction starts. The FIFO must be sized to account for the maximum latency that can be incurred by the system memory bus. More information about FIFO sizing is presented in section .

#### **41.5.6.3.3.4 Priming Receive Endpoints**

Priming receive endpoints is identical to priming of transmit endpoints from the point of view of the DCD. At the device controller the major difference in the operational model is that there is no data movement of the leading packet data simply because the data is to be received from the host.

Note as part of the architecture, the FIFO for the receive endpoints is not partitioned into multiple channels like the transmit FIFO. Thus, the size of the RX FIFO does not scale with the number of endpoints.

#### **41.5.6.4 Operational Model For Packet Transfers**

All transactions on the USB bus are initiated by the host and in turn, the device must respond to any request from the host within the turnaround time stated in the USB 2.0 Specification.

At USB 1.1 Full or Low Speed rates, this turnaround time was significant and the USB 1.1 device controllers were architected so that the device controller could access main memory or interrupt a host protocol processor in order to respond to the USB 1.1

transaction. The architecture of the USB 2.0 device controller must be different because same methods will not meet USB 2.0 High-speed turnaround time requirements by simply increasing clock rate.

A USB host will send requests to the device controller in an order that can not be precisely predicted as a single pipeline, so it is not possible to prepare a single packet for the device controller to execute. However, the order of packet requests is predictable when the endpoint number and direction is considered. For example, if endpoint 3 (transmit direction) is configured as a bulk pipe, then we can expect the host will send IN requests to that endpoint. This device controller is architected in such a way that it can prepare packets for each endpoint/direction in anticipation of the host request. The process of preparing the device controller to send or receive data in response to host initiated transaction on the bus is referred to as "priming" the endpoint. This term will be used throughout the following documentation to describe the device controller operation so the DCD can be architected properly use priming. Further, note that the term "flushing" is used to describe the action of clearing a packet that was queued for execution.

#### 41.5.6.4.1 Interrupt/Bulk Endpoint Operational Model

The behaviors of the device controller for interrupt and bulk endpoints are identical.

All valid IN and OUT transactions to bulk pipes will handshake with a NAK unless the endpoint had been primed. Once the endpoint has been primed, data delivery will commence.

A dTD will be retired by the device controller when the packets described in the transfer descriptor have been completed. Each dTD describes N packets to be transferred according to the USB Variable Length transfer protocol. The formula and table on the following page describe how the device controller computes the number and length of the packets to be sent/received by the USB vary according to the total number of bytes and maximum packet length.

With Zero Length Termination (ZLT) = 0

$$N = \text{INT}(\text{Number Of Bytes}/\text{Max. Packet Length}) + 1$$

With Zero Length Termination (ZLT) = 1

$$N = \text{MAXINT}(\text{Number Of Bytes}/\text{Max. Packet Length})$$

**Table 41-68. Variable Length Transfer Protocol Example (ZLT = 0)**

Bytes (dTD)	Max. Packet Length (dQH)	N	P1	P2	P3
511	256	2	256	255	

*Table continues on the next page...*

**Table 41-68. Variable Length Transfer Protocol Example (ZLT = 0) (continued)**

512	256	3	256	256	0
512	512	2	512	0	

**Table 41-69. Variable Length Transfer Protocol Example (ZLT = 1)**

Bytes (dTD)	Max. Packet Length (dQH)	N	P1	P2	P3
511	256	2	256	255	
512	256	2	256	256	
512	512	1	512		

**NOTE**

The MULT field in the dQH must be set to "00" for bulk, interrupt, and control endpoints.

TX-dTD is complete when:

- All packets described dTD were successfully transmitted. \*\*\* Total bytes in dTD will equal zero when this occurs.

RX-dTD is complete when:

- All packets described in dTD were successfully received. \*\*\* Total bytes in dTD will equal zero when this occurs.
- A short packet (number of bytes < maximum packet length) was received. \*\*\* This is a successful transfer completion; DCD must check Total Bytes in dTD to determine the number of bytes that are remaining. From the total bytes remaining in the dTD, the DCD can compute the actual bytes received.
- A long packet was received (number of bytes > maximum packet size) OR (total bytes received > total bytes specified). \*\*\* This is an error condition. The device controller will discard the remaining packet, and set the Buffer Error bit in the dTD. In addition, the endpoint will be flushed and the USBERR interrupt will become active.

On the successful completion of the packet(s) described by the dTD, the active bit in the dTD will be cleared and the next pointer will be followed when the Terminate bit is clear. When the Terminate bit is set, the device controller will flush the endpoint/direction and cease operations for that endpoint/direction.

On the unsuccessful completion of a packet (see long packet above), the dQH will be left pointing to the dTD that was in error. In order to recover from this error condition, the DCD must properly reinitialize the dQH by clearing the active bit and update the nextTD pointer before attempting to re-prime the endpoint.

**NOTE**

All packet level errors such as a missing handshake or CRC error will be retried automatically by the device controller.

There is no required interaction with the DCD for handling such errors.

**41.5.6.4.1.1 Interrupt/Bulk Endpoint Bus Response Matrix**

The table below shows the response matrix for Interrupt/Bulk Endpoint Bus.

**Table 41-70. Interrupt/Bulk Endpoint Bus Response Matrix**

	Stall	Not Primed	Primed	Underflow	Overflow
Setup	Ignore	Ignore	Ignore	N/A	N/A
In	STALL	NAK	Transmit	BS Error	N/A
Out	STALL	NAK	Receive + NYET/ACK	N/A	NAK
Ping	STALL	NAK	ACK	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

**NOTE**

BS Error = Force Bit Stuff Error

NYET/ACK - NYET unless the Transfer Descriptor has packets remaining according to the USB variable length protocol then ACK.

SYSERR - System error should never occur when the latency FIFOs are correctly sized and the DCD is responsive.

**41.5.6.4.2 Control Endpoint Operation Model**

This section details the setup phase, data phase, status phase, and the control endpoint bus response matrix.

**41.5.6.4.2.1 Setup Phase**

All requests to a control endpoint begin with a setup phase followed by an optional data phase and a required status phase. The device controller will always accept the setup phase unless the setup lockout is engaged.

The setup lockout will engage so that future setup packets are ignored. Lockout of setup packets ensures that while software is reading the setup packet stored in the queue head, that data is not written as it is being read potentially causing an invalid setup packet.

The setup lockout mechanism can be disabled and a new tripwire type semaphore will ensure that the setup packet payload is extracted from the queue head without being corrupted by an incoming setup packet. This is the preferred behavior because ignoring repeated setup packets due to long software interrupt latency would be a compliance issue.

- Disable Setup Lockout by writing 1 to Setup Lockout Mode (SLOM) in [USB Device Mode \(USB\\_nUSBMODE\)](#). (once at initialization). Setup lockout is not necessary when using the tripwire as described below.

### NOTE

Leaving the Setup Lockout Mode As 0 will result in pre-2.3 hardware behavior.

- After receiving an interrupt and inspecting [Endpoint Setup Status \(USB\\_nENDPTSETUPSTAT\)](#) to determine that a setup packet was received on a particular pipe:
  - a. Write 1 to clear corresponding bit [Endpoint Setup Status \(USB\\_nENDPTSETUPSTAT\)](#).
  - b. Write 1 to Setup Tripwire (SUTW) in [USB Command Register \(USB\\_nUSBCMD\)](#) register.
  - c. Duplicate contents of dQH.SetupBuffer into local software byte array.
  - d. Read Setup TripWire (SUTW) in [USB Command Register \(USB\\_nUSBCMD\)](#) register. (if set - continue; if cleared - goto 2)
  - e. Write 0 to clear Setup Tripwire (SUTW) in [USB Command Register \(USB\\_nUSBCMD\)](#) register.
  - f. Process setup packet using local software byte array copy and execute status/handshake phases.

### NOTE

After receiving a new setup packet the status and/or handshake phases may still be pending from a previous control sequence. These should be flushed & deallocated before linking a new status and/or handshake dTD for the most recent setup packet.

#### 41.5.6.4.2.2 Data Phase

Following the setup phase, the DCD must create a device transfer descriptor for the data phase and prime the transfer.

After priming the packet, the DCD must verify a new setup packet has not been received by reading the USB.ENDPTSETUPSTAT register immediately verifying that the prime had completed. A prime will complete when the associated bit in the [Endpoint Prime \(USB\\_nENDPTPRIME\)](#) register is zero and the associated bit in the [Endpoint Status](#)

(USB\_nENDPTSTAT) register is a one. If a prime fails, ie. The **Endpoint Prime (USB\_nENDPTPRIME)** bit goes to zero and the **Endpoint Status (USB\_nENDPTSTAT)** bit is not set, then the prime has failed. This can only be due to improper setup of the dQH, dTD or a setup arriving during the prime operation. If a new setup packet is indicated after the ENDPTPRIME bit is cleared, then the transfer descriptor can be freed and the DCD must reinterpret the setup packet.

Should a setup arrive after the data stage is primed, the device controller will automatically clear the prime status (**Endpoint Status (USB\_nENDPTSTAT)**) to enforce data coherency with the setup packet.

#### NOTE

- The MULT field in the dQH must be set to "00" for bulk, interrupt, and control endpoints.
- Error handling of data phase packets is the same as bulk packets described previously.

#### 41.5.6.4.2.3 Status Phase

Similar to the data phase, the DCD must create a transfer descriptor (with byte length equal zero) and prime the endpoint for the status phase.

The DCD must also perform the same checks of the USB.ENDPTSETUPSTAT as described above in the data phase.

#### NOTE

- The MULT field in the dQH must be set to 00 for bulk, interrupt, and control endpoints.
- Error handling of data phase packets is the same as bulk packets described previously.

#### 41.5.6.4.2.4 Control Endpoint Bus Response Matrix

Shown in the following table is the device controller response to packets on a control endpoint according to the device controller state.

The table below shows the response matrix for the Control Endpoint Bus.

**Table 41-71. Control Endpoint Bus Response Matrix**

Token Type	Endpoint State					Setup Lockout
	Stall	Not Primed	Primed	Underflow	Overflow	
Setup	ACK	ACK	ACK	N/A	SYSEERR	
In	STALL	NAK	Transmit	BS Error	N/A	N/A

*Table continues on the next page...*

**Table 41-71. Control Endpoint Bus Response Matrix (continued)**

Out	STALL	NAK	Receive + NYET/ACK	N/A	NAK	N/A
Ping	STALL	NAK	ACK	N/A	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore	Ignore

BS Error = Force Bit Stuff Error

NYET/ACK - NYET unless the Transfer Descriptor has packets remaining according to the USB variable length protocol then ACK.

SYSERR - System error should never occur when the latency FIFOs are correctly sized and the DCD is responsive.

#### 41.5.6.4.3 Isochronous Endpoint Operational Model

Isochronous endpoints are used for real-time scheduled delivery of data and their operational model is significantly different than the host throttled Bulk, Interrupt, and Control data pipes.

Real time delivery by the device controller will be accomplished by the following:

- Exactly MULT Packets per (micro) Frame are transmitted/received. Note: MULT is a two-bit field in the device Queue Head. The variable length packet protocol is not used on isochronous endpoints.
- NAK responses are not used. Instead, zero length packets are sent in response to an IN request to an unprimed endpoints. For unprimed RX endpoints, the response to an OUT transaction is to ignore the packet within the device controller.
- Prime requests always schedule the transfer described in the dTD for the next (micro) frame. If the ISO-dTD is still active after that frame, then the ISO-dTD will be held ready until executed or canceled by the DCD.

An EHCI compatible host controller uses the periodic frame list to schedule data exchanges to Isochronous endpoints. The operational model for device mode does not use such a data structure. Instead, the same dTD used for Control/Bulk/Interrupt endpoints is also used for isochronous endpoints. The difference is in the handling of the dTD.

The first difference between bulk and ISO-endpoints is that priming an ISO-endpoint is a delayed operation such that an endpoint will become primed only after a SOF is received. After the DCD writes the prime bit, the prime bit will be cleared as usual to indicate to software that the device controller completed a priming the dTD for transfer. Internal to the design, the device controller hardware masks that prime start until the next frame boundary. This behavior is hidden from the DCD but occurs so that the device controller can match the dTD to a specific (micro)frame.

Another difference with isochronous endpoints is that the transaction must wholly complete in a (micro)frame. Once an ISO transaction is started in a (micro)frame it will retire the corresponding dTD when MULT transactions occur or the device controller finds a fulfillment condition.

The transaction error bit set in the status field indicates a fulfillment error condition. When a fulfillment error occurs, the frame after the transfer failed to complete wholly, the device controller will force retire the ISO-dTD and move to the next ISO-dTD.

It is important to note that fulfillment errors are only caused due to partially completed packets. If no activity occurs to a primed ISO-dTD, the transaction will stay primed indefinitely. This means it is up to software discard transmit ISO-dTDs that pile up from a failure of the host to move the data.

Finally, the last difference with ISO packets is in the data level error handling. When a CRC error occurs on a received packet, the packet is not retried similar to bulk and control endpoints. Instead, the CRC is noted by setting the *Transaction Error* bit and the data is stored as usual for the application software to sort out.

- TX Packet Retired
  - MULT counter reaches zero.
  - Fulfillment Error [*Transaction Error* bit is set]
    - # Packets Occurred > 0 AND # Packets Occurred < MULT

#### NOTE

For TX-ISO, MULT Counter can be loaded with a lesser value in the dTD Multiplier Override field in hardware versions 2.3 and later. If the Multiplier Override is zero, the MULT Counter is initialized to the Multiplier in the QH.

- RX Packet Retired:
  - MULT counter reaches zero.
  - Non-MDATA Data PID is received\*\*
    - \*\* Exit criteria only valid in hardware version 2.3 or later. Previous to hardware version 2.3, any PID sequence that did not match the MULT field exactly would be flagged as a transaction error due to PID mismatch or fulfillment error.
  - Overflow Error:
    - Packet received is > maximum packet length. [*Buffer Error* bit is set]
    - Packet received exceeds total bytes allocated in dTD. [*Buffer Error* bit is set]
  - Fulfillment Error [*Transaction Error* bit is set]
    - # Packets Occurred > 0 AND # Packets Occurred < MULT
  - CRC Error [*Transaction Error* bit is set]

**NOTE**

For ISO, when a dTD is retired, the next dTD is primed for the next frame. For continuous (micro)frame to (micro)frame operation the DCD should ensure that the dTD linked-list is out ahead of the device controller by at least two (micro)frames.

**41.5.6.4.3.1 Isochronous Pipe Synchronization**

When it is necessary to synchronize an isochronous data pipe to the host, the (micro) frame number (USB\_UOG\_FRINDEX register) can be used as a marker.

To cause a packet transfer to occur at a specific (micro) frame number [N], the DCD should interrupt on SOF during frame N-1. When the USB\_UOG\_FRINDEX=N-1, the DCD must write the prime bit. The device controller will prime the isochronous endpoint in (micro) frame N-1 so that the device controller will execute delivery during (micro) frame N.

**NOTE**

Priming an endpoint towards the end of (micro) frame N-1 will not guarantee delivery in (micro) frame N. The delivery may actually occur in (micro) frame N+1 if device controller does not have enough time to complete the prime before the SOF for packet N is received.

**41.5.6.4.3.2 Isochronous Endpoint Bus Response Matrix**

The following table shows the response matrix for the Isochronous Endpoint Bus.

**Table 41-72. Isochronous Endpoint Bus Response Matrix**

	Stall	Not Primed	Primed	Underflow	Overflow
Setup	STALL	STALL	STALL	N/A	N/A
In	NULL Packet	NULL Packet	Transmit	BS Error	N/A
Out	Ignore	Ignore	Receive	N/A	Drop Packet
Ping	Ignore	Ignore	Ignore	Ignore	Ignore
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

1. BS Error = Force Bit Stuff Error

NULL Packet = Zero Length Packet

### 41.5.6.5 Managing Queue Heads

The following figure shows the End Point Queue Head.

**Figure 41-29. End Point Queue Head Diagram**

The device queue head (dQH) points to the linked list of transfer tasks, each depicted by the device Transfer Descriptor (dTd). An area of memory pointed to by `USB.ENDPOINTLISTADDR` contains a group of all dQH's in a sequential list as shown in [Figure 41-29](#). The even elements in the list of dQH's are used for receive endpoints (OUT/SETUP) and the odd elements are used for transmit endpoints (IN/INTERRUPT). Device transfer descriptors are linked head to tail starting at the queue head and ending at a terminate bit. Once the dTd has been retired, it will no longer be part of the linked list from the queue head. Therefore, software is required to track all transfer descriptors because pointers will no longer exist within the queue head once the dTd is retired (see section [Software Link Pointers](#)).

In addition to the current and next pointers and the dTd overlay examined in section [Operational Model For Packet Transfers](#), the dQH also contains the following parameters for the associated endpoint: Multiplier, Maximum Packet Length, Interrupt On Setup. The complete initialization of the dQH including these fields is demonstrated in the next section.

#### 41.5.6.5.1 Queue Head Initialization

One device queue head must be initialized for each active endpoint.

To initialize a device queue head:

- Write the `wMaxPacketSize` field as required by the USB Chapter 9 or application specific protocol.
- Write the multiplier field to 0 for control, bulk, and interrupt endpoints. For ISO endpoints, set the multiplier to 1,2, or 3 as required bandwidth and in conjunction with the USB Chapter 9 protocol.

**NOTE**

In FS mode, the multiplier field can only be 1 for ISO endpoints.

- Write the next `dTD Terminate` bit field to 1.
- Write the `Active` bit in the status field to 0.
- Write the `Halt` bit in the status field to 0.

**NOTE**

The DCD must only modify `dQH` if the associated endpoint is not primed and there are no outstanding `dTD`'s.

**41.5.6.5.2 Operational Model For Setup Transfers**

As discussed in section [Control Endpoint Operation Model](#), setup transfer requires special treatment by the DCD. A setup transfer does not use a `dTD` but instead stores the incoming data from a setup packet in an 8-byte buffer within the `dQH`.

Upon receiving notification of the setup packet, the DCD should handle the setup transfer as demonstrated here:

1. Copy setup buffer contents from `dQH - RX` to software buffer.
2. Acknowledge setup backup by writing a "1" to the corresponding bit in `ENDPTSETUPSTAT`.

**NOTE**

- The acknowledge must occur before continuing to process the setup packet.
  - After the acknowledge has occurred, the DCD must not attempt to access the setup buffer in the `dQH - RX`. Only the local software copy should be examined.
3. Check for pending data or status `dTD`'s from previous control transfers and flush if any exist as discussed in section [Flushing/De-priming an Endpoint](#).
  4. Decode setup packet and prepare data phase [optional] and status phase transfer as required by the USB Chapter 9 or application specific protocol.

**NOTE**

It is possible for the device controller to receive setup packets before previous control transfers complete. Existing control packets in progress must be flushed and the new control packet completed.

**41.5.6.6 Managing Transfers with Transfer Descriptors****41.5.6.6.1 Software Link Pointers**

It is necessary for the DCD software to maintain head and tail pointers to the for the linked list of dTDs for each respective queue head.

This is necessary because the dQH only maintains pointers to the current working dTD and the next dTD to be executed. The operations described in next section for managing dTD will assume the DCD can use reference the head and tail of the dTD linked list. The following figure shows the Software Link Pointers.

**Figure 41-30. Software Link Pointers**

**NOTE**

To conserve memory, the reserved fields at the end of the dQH can be used to store the Head & Tail pointers, but it still remains the responsibility of the DCD to maintain the pointers.

**41.5.6.6.2 Building a Transfer Descriptor**

Before a transfer can be executed from the linked list, a dTD must be built to describe the transfer.

Use the following procedure for building dTDs.

Allocate 8-DWord dTD block of memory aligned to 8-DWord boundaries. Example: bit address 4:0 would be equal to "00000"

Write the following fields:

1. Initialize first 7 DWords to 0.
2. Set the terminate bit to 1.
3. Fill in total bytes with transfer size.
4. Set the interrupt on complete if desired.
5. Initialize the status field with the active bit set to 1 and all remaining status bits set to 0.
6. Fill in buffer pointer page 0 and the current offset to point to the start of the data buffer.
7. Initialize buffer pointer page 1 through page 4 to be one greater than each of the previous buffer pointer.

#### 41.5.6.6.3 Executing A Transfer Descriptor

To safely add a dTD, the DCD must follow this procedure which will handle the event where the device controller reaches the end of the dTD list at the same time a new dTD is being added to the end of the list.

Determine whether the link list is empty: Check DCD driver to see if pipe is empty (internal representation of linked-list should indicate if any packets are outstanding).

- Case 1: Link list is empty
  - a. Write dQH next pointer AND dQH terminate bit to 0 as a single DWord operation.
  - b. Clear active & halt bit in dQH (in case set from a previous error).
  - c. Prime endpoint by writing 1 to correct bit position in [Endpoint Prime \(USB\\_nENDPTPRIME\)](#).
- Case 2: Link list is not empty
  - a. Add dTD to end of linked list.
  - b. Read correct prime bit in [Endpoint Prime \(USB\\_nENDPTPRIME\)](#)- if 1 DONE.
  - c. Set ATDTW bit in USBCMD register to 1.
  - d. Read correct status bit in [Endpoint Status \(USB\\_nENDPTSTAT\)](#). (store in tmp. variable for later)
  - e. Read ATDTW bit in USBCMD register.
    - If 0 goto 3.
    - If 1 continue to 6.
  - f. Write ATDTW bit in USBCMD register to 0.
  - g. If status bit read in (3) is 1 DONE.

h. If status bit read in (3) is 0 then Goto Case 1: Step 1.

#### 41.5.6.6.4 Transfer Completion

After a dTD has been initialized and the associated endpoint primed the device controller will execute the transfer upon the host-initiated request. The DCD will be notified with a USB interrupt if the Interrupt On Complete bit was set or alternately, the DCD can poll the endpoint complete register to find when the dTD had been executed. After a dTD has been executed, DCD can check the status bits to determine success or failure.

#### NOTE

Multiple dTD can be completed in a single endpoint complete notification. After clearing the notification, DCD must search the dTD linked list and retire all dTDs that have finished (Active bit cleared).

By reading the status fields of the completed dTDs, the DCD can determine if the transfers completed successfully. Success is determined with the following combination of status bits:

- Active = 0
- Halted = 0
- Transaction Error = 0
- Data Buffer Error = 0

Should any combination other than the one shown above exist, the DCD must take proper action. Transfer failure mechanisms are indicated in the [Device Error Matrix](#).

In addition to checking the status bit the DCD must read the Transfer Bytes field to determine the actual bytes transferred. When a transfer is complete, the Total Bytes transferred is by decremented by the actual bytes transferred. For Transmit packets, a packet is only complete after the actual bytes reaches zero, but for receive packets, the host may send fewer bytes in the transfer according the USB variable length packet protocol.

#### 41.5.6.6.5 Flushing/De-priming an Endpoint

It is necessary for the DCD to flush to de-prime one more endpoints on a USB device reset or during a broken control transfer.

There may also be application specific requirements to stop transfers in progress. The following procedure can be used by the DCD to stop a transfer in progress:

1. Write a '1' to the corresponding bit(s) in [Endpoint Flush \(USB\\_nENDPTFLUSH\)](#).
2. Wait until all bits in [Endpoint Flush \(USB\\_nENDPTFLUSH\)](#) are '0'.

- Software note: this operation may take a large amount of time depending on the USB bus activity. It is not desirable to have this wait loop within an interrupt service routine.
3. Read [Endpoint Status \(USB\\_nENDPTSTAT\)](#) to ensure that for all endpoints commanded to be flushed, that the corresponding bits are now '0'. If the corresponding bits are '1' after step #2 has finished, then the flush failed as described in the following:
- Explanation: In very rare cases, a packet is in progress to the particular endpoint when commanded flush using [Endpoint Flush \(USB\\_nENDPTFLUSH\)](#). A safeguard is in place to refuse the flush to ensure that the packet in progress completes successfully. The DCD may need to repeatedly flush any endpoints that fail to flush by repeating steps 1-3 until each endpoint is successfully flushed.

#### 41.5.6.6.6 Device Error Matrix

The following table summarizes packet errors that are not automatically handled by the Device Controller.

**Table 41-73. Device Error Matrix**

Error	Direction	Packet Type	Data Buffer Error Bit	Transaction Error Bit
Overflow **	RX	Any	1	0
ISO Packet Error	RX	ISO	0	1
ISO Fulfillment Error	Both	ISO	0	1

Notice that the device controller handles all errors on Bulk/Control/Interrupt Endpoints except for a data buffer overflow. However, for ISO endpoints, errors packets are not retried and errors are tagged as indicated. The table below describes the errors.

**Table 41-74. Error Descriptions**

Error	Description
Overflow	Number of bytes received exceeded max. packet size or total buffer length.  ** This error will also set the Halt bit in the dQH and if there are dTDs remaining in the linked list for the endpoint, then those will not be executed.
ISO Packet Error	CRC Error on received ISO packet. Contents not guaranteed to be correct.
ISO Fulfillment Error	Host failed to complete the number of packets defined in the dQH mult field within the given (micro)frame. For scheduled data delivery the DCD may need to readjust the data queue because a fulfillment error will cause Device Controller to cease data transfers on the pipe for one (micro)frame. During the "dead" (micro)frame, the Device Controller reports error on the pipe and primes for the following frame.

## 41.5.6.7 Servicing Interrupts

The interrupt service routine must consider that there are high-frequency, low-frequency operations, and error operations and order accordingly.

### 41.5.6.7.1 High-Frequency Interrupts

High frequency interrupts in particular should be handled in the order below. The most important of these is listed first because the DCD must acknowledge a setup buffer in the timeliest manner possible.

The table below describes the High frequency interrupt events.

**Table 41-75. High Frequency Interrupt Events**

Execution Order	Interrupt	Action
1a	USB Interrupt - USB.ENDPTSETUPSTATUS	Copy contents of setup buffer and acknowledge setup packet (as indicated in <a href="#">Figure 41-29</a> shows the End Point Queue Head). Process setup packet according to USB 2.0 Chapter 9 or application specific protocol.
1b	USB Interrupt <sup>1</sup> - USB.ENDPTCOMPLETE	Handle completion of dTD as indicated in <a href="#">Figure 41-29</a> shows the End Point Queue Head.
2	SOF Interrupt	Action as deemed necessary by application. This interrupt may not have a use in all applications.

1. It is likely that multiple interrupts to stack up on any call to the Interrupt Service Routine AND during the Interrupt Service Routine.

### 41.5.6.7.2 Low-Frequency Interrupts

The low frequency interrupts can be handled in any order because they do not occur often in comparison to the high-frequency interrupts.

The table below shows the Low frequency interrupt events.

**Table 41-76. Low Frequency Interrupt Events**

Interrupt	Action
Port Change	Change software state information.
Sleep Enable (Suspend)	Change software state information. Low power handling as necessary.
Reset Received	Change software state information. Abort pending transfers.

### 41.5.6.7.3 Error Interrupts

Error interrupts will be least frequent and should be placed last in the interrupt service routine.

The following table shows the error interrupt events.

**Table 41-77. Error Interrupt Events**

Interrupt	Action
USB Error Interrupt	This error is redundant because it combines USB Interrupt and an error status in the dTD. The DCD will more aptly handle packet-level errors by checking dTD status field upon receipt of USB Interrupt (w/ USB.ENDPTCOMPLETE).
System Error	Unrecoverable error. Immediate Reset of core; free transfers buffers in progress and restart the DCD.

## 41.6 USB Non-Core Memory Map/Register Definition

There are two kinds of registers in the USB module: USB core registers and USB non-core registers.

USB core registers are used to control USB core functions, and more independent of USB features. Each USB controller core has its own core registers.

USB non-core registers are additional to USB core registers, and more dependent on USB features. i.MX series products vary in non-core registers.

This section describes only the USB non-core registers. For detailed descriptions of USB core registers, please refer to [Register Interface](#).

### NOTE

- For reserved bits, please preserve the value when writing (read its reset value, then write this value back)
- "USB\_UOG1\_", "USB\_UOG2\_" prefix in register name indicates it is a core register for OTG1/OTG2 controller core respectively.
- USBNC\_USB\_" prefix in register name indicates it is a USB non-core register.

## USBNC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
402E_0800	USB OTG1 Control Register (USBNC_USB_OTG1_CTRL)	32	R/W	3000_1000h	<a href="#">41.6.1/2474</a>
402E_0804	USB OTG2 Control Register (USBNC_USB_OTG2_CTRL)	32	R/W	3000_1000h	<a href="#">41.6.2/2477</a>
402E_0818	OTG1 UTMI PHY Control 0 Register (USBNC_USB_OTG1_PHY_CTRL_0)	32	R/W	0000_0000h	<a href="#">41.6.3/2480</a>
402E_081C	OTG2 UTMI PHY Control 0 Register (USBNC_USB_OTG2_PHY_CTRL_0)	32	R/W	0000_0098h	<a href="#">41.6.4/2481</a>

### 41.6.1 USB OTG1 Control Register (USBNC\_USB\_OTG1\_CTRL)

The USB OTG1 control register controls the integration specific features of the USB OTG1 module. These features are not directly related to the USB functionality, but control special features, interfacing on the USB ports, as well as power control and wake-up functionality.

Address: 402E\_0000h base + 800h offset = 402E\_0800h

### USBNC\_USB\_OTG1\_CTRL field descriptions

Field	Description
31 WIR	OTG1 Wake-up Interrupt Request This bit indicates that a wake-up interrupt request is received on the OTG1 port. This bit is cleared by disabling the wake-up interrupt (clearing bit "OWIE"). 1 Wake-up Interrupt Request received 0 No wake-up interrupt request received
30 -	This field is reserved. Reserved
29 WKUP_DPDM_EN	Wake-up on DPDM change enable 1 (Default) DPDM changes wake-up to be enabled, it is for device only. 0 DPDM changes wake-up to be disabled only when VBUS is 0.
28–18 -	This field is reserved. Reserved
17 WKUP_VBUS_EN	OTG1 wake-up on VBUS change enable 1 Enable 0 Disable
16 WKUP_ID_EN	OTG1 Wake-up on ID change enable 1 Enable 0 Disable
15 WKUP_SW	OTG1 Software Wake-up 1 Force wake-up 0 Inactive

Table continues on the next page...

**USBNC\_USB\_OTG1\_CTRL field descriptions (continued)**

Field	Description
14 WKUP_SW_EN	OTG1 Software Wake-up Enable 1 Enable 0 Disable
13–11 -	This field is reserved. Reserved
10 WIE	OTG1 Wake-up Interrupt Enable This bit enables or disables the OTG1 wake-up interrupt. Disabling the interrupt also clears the Interrupt request bit. Wake-up interrupt enable should be turned off after receiving a wake-up interrupt and turned on again prior to going in suspend mode 1 Interrupt Enabled 0 Interrupt Disabled
9 PWR_POL	OTG1 Power Polarity This bit should be set according to PMIC Power Pin polarity. 1 PMIC Power Pin is High active. 0 PMIC Power Pin is Low active.
8 OVER_CUR_POL	OTG1 Polarity of Overcurrent The polarity of OTG1 port overcurrent event 1 Low active (low on this signal represents an overcurrent condition) 0 High active (high on this signal represents an overcurrent condition)
7 OVER_CUR_DIS	Disable OTG1 Overcurrent Detection 1 Disables overcurrent detection 0 Enables overcurrent detection
-	This field is reserved. Reserved

## 41.6.2 USB OTG2 Control Register (USBNC\_USB\_OTG2\_CTRL)

The USB OTG2 control register controls the integration specific features of the USB OTG2 module. These features are not directly related to the USB functionality, but control special features, interfacing on the USB ports, as well as power control and wake-up functionality.

Address: 402E\_0000h base + 804h offset = 402E\_0804h

## USB Non-Core Memory Map/Register Definition

### USBNC\_USB\_OTG2\_CTRL field descriptions

Field	Description
31 WIR	OTG2 Wake-up Interrupt Request This bit indicates that a wake-up interrupt request is received on the OTG port. This bit is cleared by disabling the wake-up interrupt (clearing bit "OWIE"). 1 Wake-up Interrupt Request received 0 No wake-up interrupt request received
30 -	This field is reserved. Reserved
29 WKUP_DPDM_EN	Wake-up on DPDM change enable 1 (Default) DPDM changes wake-up to be enabled, it is for device only. 0 DPDM changes wake-up to be disabled only when VBUS is 0.
28-18 -	This field is reserved. Reserved
17 WKUP_VBUS_EN	OTG2 wake-up on VBUS change enable 1 Enable 0 Disable
16 WKUP_ID_EN	OTG2 Wake-up on ID change enable 1 Enable 0 Disable
15 WKUP_SW	OTG2 Software Wake-up 1 Force wake-up 0 Inactive

Table continues on the next page...

## USBNC\_USB\_OTG2\_CTRL field descriptions (continued)

Field	Description
14 WKUP_SW_EN	OTG2 Software Wake-up Enable 1 Enable 0 Disable
13–11 -	This field is reserved. Reserved
10 WIE	OTG2 Wake-up Interrupt Enable This bit enables or disables the OTG2 wake-up interrupt. Disabling the interrupt also clears the Interrupt request bit. Wake-up interrupt enable should be turned off after receiving a wake-up interrupt and turned on again prior to going in suspend mode 1 Interrupt Enabled 0 Interrupt Disabled
9 PWR_POL	OTG2 Power Polarity This bit should be set according to PMIC Power Pin polarity. 1 PMIC Power Pin is High active. 0 PMIC Power Pin is Low active.
8 OVER_CUR_POL	OTG2 Polarity of Overcurrent The polarity of OTG2 port overcurrent event 1 Low active (low on this signal represents an overcurrent condition) 0 High active (high on this signal represents an overcurrent condition)
7 OVER_CUR_DIS	Disable OTG2 Overcurrent Detection 1 Disables overcurrent detection 0 Enables overcurrent detection
-	This field is reserved. Reserved

### 41.6.3 OTG1 UTMI PHY Control 0 Register (USBNC\_USB\_OTG1\_PHY\_CTRL\_0)

USB OTG1 UTMI PHY control register 0 is used to control the on-chip OTG1 UTMI PHY.

Address: 402E\_0000h base + 818h offset = 402E\_0818h

#### USBNC\_USB\_OTG1\_PHY\_CTRL\_0 field descriptions

Field	Description
31 UTMI_CLK_VLD	Indicating whether OTG1 UTMI PHY clock is valid 1 Valid 0 Invalid
30-3 -	This field is reserved. Reserved
-	This field is reserved. Reserved

## 41.6.4 OTG2 UTMI PHY Control 0 Register (USBNC\_USB\_OTG2\_PHY\_CTRL\_0)

USB OTG2 UTMI PHY Control Register 0 are used to control the on-chip OTG2 UTMI PHY.

Address: 402E\_0000h base + 81Ch offset = 402E\_081Ch

### 41.7.1 Identification register (USB\_nID)

The ID register identifies the USB 2.0 High-Speed core and its revision.

Address: 402E\_0000h base + 0h offset + (512d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved								REVISION							
W	Reserved								Reserved							
Reset	1	1	1	0	0	1	0	0	1	0	1	0	0	0	0	1
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved		NID						Reserved		ID					
W	Reserved		Reserved						Reserved		Reserved					
Reset	1	1	1	1	1	0	1	0	0	0	0	0	0	1	0	1

#### USB\_nID field descriptions

Field	Description
31–24 -	This field is reserved. Reserved
23–16 REVISION	Revision number of the controller core.
15–14 -	This field is reserved. Reserved
13–8 NID	Complement version of ID
7–6 -	This field is reserved. Reserved
ID	Configuration number. This number is set to 0x05 and indicates that the peripheral is USB 2.0 High-Speed core.

### 41.7.2 Hardware General (USB\_nHWGENERAL)

General hardware parameters as defined in System Level Issues and Core Configuration.

#### NOTE

The reset value could vary from instance to instance. Please see the detail in bit field description and ignore reset value in summary table in this case!

Address: 402E\_0000h base + 4h offset + (512d × i), where i=0d to 1d

**USB\_nHWGENERAL field descriptions**

Field	Description
31–11 -	This field is reserved. Reserved
10–9 SM	Serial interface mode capability  00 No Serial Engine, always use parallel signalling. 01 Serial Engine present, always use serial signalling for FS/LS. 10 Software programmable - Reset to use parallel signalling for FS/LS 11 Software programmable - Reset to use serial signalling for FS/LS
8–6 PHYM	Transceiver type  000 UTMI/UMTI+ 001 ULPI DDR 010 ULPI 011 Serial Only 100 Software programmable - reset to UTMI/UTMI+ 101 Software programmable - reset to ULPI DDR 110 Software programmable - reset to ULPI 111 Software programmable - reset to Serial 1000 IC-USB 1001 Software programmable - reset to IC-USB
5–4 PHYW	Data width of the transceiver connected to the controller core. PHYW bit reset value is  00 8 bit wide data bus Software non-programmable  01 16 bit wide data bus Software non-programmable  10 Reset to 8 bit wide data bus Software programmable  11 Reset to 16 bit wide data bus Software programmable

R	Reserved												DEVEP		DC	
W	Reserved												Reserved		Reserved	
Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	1

### USB\_nHWDEVICE field descriptions

Field	Description
31–6 -	This field is reserved. Reserved
5–1 DEVEP	Device Endpoint Number
0 DC	Device Capable. Indicating whether device operation mode is supported or not.  1 Supported 0 Not supported

### 41.7.5 TX Buffer Hardware Parameters (USB\_nHWTXBUF)

Address: 402E\_0000h base + 10h offset + (512d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
R	Reserved								TXCHANADD								Reserved								TXBURST								
W	Reserved								Reserved								Reserved								Reserved								
Reset	1	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1	0	1	1	0	0	0	0	1	0	0	0

### USB\_nHWTXBUF field descriptions

Field	Description
31–24 -	This field is reserved. Reserved
23–16 TXCHANADD	TX FIFO Buffer size is: $(2^{\text{TXCHANADD}}) * 4$ Bytes. These bits are set to '08h', so buffer size is $256 * 4$ Bytes.  For the OTG controller operating in device mode, this is the FIFO buffer size per endpoint. As the OTG controller has 8 TX endpoint, there are 8 of these buffers.  For the OTG controller operating in host mode, or for Host-only controller, the entire buffer memory is used as a single TX buffer. Therefore, there is only 1 of this buffer
15–8 -	This field is reserved. Reserved
TXBURST	Default burst size for memory to TX buffer transfer.  This is reset value of TXPBURST bits in USB core register USB_n_BURSTSIZE.  Please see <a href="#">Programmable Burst Size (USB_nBURSTSIZE)</a> .

### 41.7.6 RX Buffer Hardware Parameters (USB\_nHWRXBUF)

Address: 402E\_0000h base + 14h offset + (512d × i), where i=0d to 1d

#### USB\_nHWRXBUF field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
15–8 RXADD	Buffer total size for all receive endpoints is (2^RXADD). RX Buffer size is: (2^RXADD) * 4 Bytes. These bits are set to '08h', so buffer size is 256*4 Bytes. There is a single Receive FIFO buffer in the USB controller. The buffer is shared for all endpoints for the OTG controller in device mode.
RXBURST	Default burst size for memory to RX buffer transfer. This is reset value of RXPBURST bits in USB core register USB_n_BURSTSIZE. Please see <a href="#">Programmable Burst Size (USB_nBURSTSIZE)</a> .

### 41.7.7 General Purpose Timer #0 Load (USB\_nGPTIMER0LD)

This register controls load value of the count timer in register n\_GPTIMER0CTRL. Please see [General Purpose Timer #0 Controller \(USB\\_nGPTIMER0CTRL\)](#) .

Address: 402E\_0000h base + 80h offset + (512d × i), where i=0d to 1d

#### USB\_nGPTIMER0LD field descriptions

Field	Description
31–24 -	This field is reserved. Reserved
GPTLD	General Purpose Timer Load Value These bit fields are loaded to GPTCNT bits when GPTRST bit is set '1b'. This value represents the time in microseconds minus 1 for the timer duration.

Table continues on the next page...

## USB\_nGPTIMER0LD field descriptions (continued)

Field	Description
	Example: for a one millisecond timer, load 1000-1=999 or 0x0003E7. <b>NOTE:</b> Max value is 0xFFFFF or 16.777215 seconds.

### 41.7.8 General Purpose Timer #0 Controller (USB\_nGPTIMER0CTRL)

This register contains the control for this countdown timer and a data field can be queried to determine the running count value. This timer has granularity on 1 us and can be programmed to a little over 16 seconds. There are two counter modes which are described in the register table below. When the timer counter value transitions to zero, an interrupt could be generated if enable.

Interrupt status bit is TI0 bit in n\_USBSTS register (See [USB Status Register \(USB\\_nUSBSTS\)](#)), interrupt enable bit is TIE0 bit in n\_USBINTR register. (See [Interrupt Enable Register \(USB\\_nUSBINTR\)](#).)

Address: 402E\_0000h base + 84h offset + (512d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
R	GPTRUN	GPTRST	Reserved						GPTMODE	GPTCNT							
W

R	GPTCNT																
W																	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

### USB\_nGPTIMER0CTRL field descriptions

Field	Description
31 GPTRUN	General Purpose Timer Run GPTCNT bits are not effected when setting or clearing this bit.  0 Stop counting 1 Run
30 GPTRST	General Purpose Timer Reset

Table continues on the next page...

**USB\_nGPTIMER0CTRL field descriptions (continued)**

Field	Description
	0 No action 1 Load counter value from GPTLD bits in n_GPTIMER0LD
29–25 -	This field is reserved. Reserved
24 GPTMODE	General Purpose Timer Mode In one shot mode, the timer will count down to zero, generate an interrupt, and stop until the counter is reset by software; In repeat mode, the timer will count down to zero, generate an interrupt and automatically reload the counter value from GPTLD bits to start again. 0 One Shot Mode 1 Repeat Mode
GPTCNT	General Purpose Timer Counter. This field is the count value of the countdown timer.

**41.7.9 General Purpose Timer #1 Load (USB\_nGPTIMER1LD)**

This register controls load value of the count timer in register n\_GPTIMER1CTRL. Please see [General Purpose Timer #1 Controller \(USB\\_nGPTIMER1CTRL\)](#) .

Address: 402E\_0000h base + 88h offset + (512d × i), where i=0d to 1d

**USB\_nGPTIMER1LD field descriptions**

Field	Description
31–24 -	This field is reserved. Reserved
GPTLD	General Purpose Timer Load Value These bit fields are loaded to GPTCNT bits when GPTRST bit is set '1b'. This value represents the time in microseconds minus 1 for the timer duration. Example: for a one millisecond timer, load 1000-1=999 or 0x0003E7. <b>NOTE:</b> Max value is 0xFFFFF or 16.777215 seconds.

### 41.7.10 General Purpose Timer #1 Controller (USB\_nGPTIMER1CTRL)

This register contains the control for this countdown timer and a data field can be queried to determine the running count value. This timer has granularity on 1 us and can be programmed to a little over 16 seconds. There are two counter modes which are described in the register table below. When the timer counter value transitions to zero, an interrupt could be generated if enable.

Interrupt status bit is TI1 bit in USB\_n\_USBSTS register (See [USB Status Register \(USB\\_n\\_USBSTS\)](#) ), interrupt enable bit is TIE1 bit in n\_USBINTR register (See [Interrupt Enable Register \(USB\\_n\\_USBINTR\)](#) ).

Address: 402E\_0000h base + 8Ch offset + (512d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	GPTRUN	GPTRST	Reserved					GPTMODE	GPTCNT

R	GPTCNT															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### USB\_nGPTIMER1CTRL field descriptions

Field	Description
31 GPTRUN	General Purpose Timer Run GPTCNT bits are not effected when setting or clearing this bit. 0 Stop counting 1 Run
30 GPTRST	General Purpose Timer Reset 0 No action 1 Load counter value from GPTLD bits in USB_n_GPTIMEROLD
29–25 -	This field is reserved. Reserved
24 GPTMODE	General Purpose Timer Mode In one shot mode, the timer will count down to zero, generate an interrupt, and stop until the counter is reset by software. In repeat mode, the timer will count down to zero, generate an interrupt and automatically reload the counter value from GPTLD bits to start again.

Table continues on the next page...

**USB\_nGPTIMER1CTRL field descriptions (continued)**

Field	Description
	0 One Shot Mode 1 Repeat Mode
GPTCNT	General Purpose Timer Counter. This field is the count value of the countdown timer.

**41.7.11 System Bus Config (USB\_nSBUSCFG)**

Address: 402E\_0000h base + 90h offset + (512d × i), where i=0d to 1d

**USB\_nSBUSCFG field descriptions**

Field	Description
31–3 -	This field is reserved. Reserved
AHBBRST	AHB master interface Burst configuration These bits control AHB master transfer type sequence (or priority). <b>NOTE:</b> This register overrides n_BURSTSIZE register when its value is not zero.  000 Incremental burst of unspecified length only 001 INCR4 burst, then single transfer 010 INCR8 burst, INCR4 burst, then single transfer 011 INCR16 burst, INCR8 burst, INCR4 burst, then single transfer 100 Reserved, don't use 101 INCR4 burst, then incremental burst of unspecified length 110 INCR8 burst, INCR4 burst, then incremental burst of unspecified length 111 INCR16 burst, INCR8 burst, INCR4 burst, then incremental burst of unspecified length

### 41.7.12 Capability Registers Length (USB\_nCAPLENGTH)

The Capability Registers Length register contains the address offset to the Operational registers relative to the CAPLENGTH register.

Address: 402E\_0000h base + 100h offset + (512d × i), where i=0d to 1d

**USB\_nCAPLENGTH field descriptions**

Field	Description
CAPLENGTH	These bits are used as an offset to add to register base to find the beginning of the Operational Register. Default value is '40h'.

### 41.7.13 Host Controller Interface Version (USB\_nHCIVERSION)

This is a 2-byte register containing a BCD encoding of the EHCI revision number supported by this host controller. The most significant byte of this register represents a major revision and the least significant byte is the minor revision.

Address: 402E\_0000h base + 102h offset + (512d × i), where i=0d to 1d

**USB\_nHCIVERSION field descriptions**

Field	Description
HCIVERSION	Host Controller Interface Version Number Default value is '10h', which means EHCI rev1.0.

### 41.7.14 Host Controller Structural Parameters (USB\_nHCSPARAMS)

The following figure shows the port steering logic capabilities of Host Control Structural Parameters (n\_HCSPARAMS).

Address: 402E\_0000h base + 104h offset + (512d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved				N_TT				N_PTT				Reserved			PI
W	Reserved				Reserved				Reserved				Reserved			Reserved

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	N_CC				N_PCC				Reserved			PPC	N_PORTS			
W	Reserved				Reserved				Reserved			Reserved	Reserved			
Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	1

**USB\_nHCSPARAMS field descriptions**

Field	Description
31–28 -	This field is reserved. Reserved
27–24 N_TT	Number of Transaction Translators (N_TT). Default value '0000b' This field indicates the number of embedded transaction translators associated with the USB2.0 host controller. These bits would be set to '0001b' for Multi-Port Host, and '0000b' for Single-Port Host.
23–20 N_PTT	Number of Ports per Transaction Translator (N_PTT). Default value '0000b' This field indicates the number of ports assigned to each transaction translator within the USB2.0 host controller. These bits would be set to equal N_PORTS for Multi-Port Host, and '0000b' for Single-Port Host.
19–17 -	This field is reserved. Reserved
16 PI	Port Indicators (P INDICATOR) This bit indicates whether the ports support port indicator control. When set to one, the port status and control registers include a read/writeable field for controlling the state of the port indicator This bit is "1b" in all controller core.
15–12 N_CC	Number of Companion Controller (N_CC). This field indicates the number of companion controllers associated with this USB2.0 host controller. These bits are '0000b' in all controller core.  0 There is no internal Companion Controller and port-ownership hand-off is not supported. 1 There are internal companion controller(s) and port-ownership hand-offs is supported.

Table continues on the next page...

## USB\_nHCSPARAMS field descriptions (continued)

Field	Description
11–8 N_PCC	<p>Number of Ports per Companion Controller</p> <p>This field indicates the number of ports supported per internal Companion Controller. It is used to indicate the port routing configuration to the system software.</p> <p>For example, if N_PORTS has a value of 6 and N_CC has a value of 2 then N_PCC could have a value of 3. The convention is that the first N_PCC ports are assumed to be routed to companion controller 1, the next N_PCC ports to companion controller 2, etc. In the previous example, the N_PCC could have been 4, where the first 4 are routed to companion controller 1 and the last two are routed to companion controller 2. The number in this field must be consistent with N_PORTS and N_CC.</p> <p>These bits are '0000b' in all controller core.</p>
7–5 -	<p>This field is reserved.</p> <p>Reserved</p>
4 PPC	<p>Port Power Control</p> <p>This field indicates whether the host controller implementation includes port power control. A one indicates the ports have port power switches. A zero indicates the ports do not have port power switches. The value of this field affects the functionality of the Port Power field in each port status and control register</p>
N_PORTS	<p>Number of downstream ports. This field specifies the number of physical downstream ports implemented on this host controller. The value of this field determines how many port registers are addressable in the Operational Register.</p> <p>Valid values are in the range of 1h to Fh. A zero in this field is undefined.</p> <p>These bits are always set to '0001b' because all controller cores are Single-Port Host.</p>

### 41.7.15 Host Controller Capability Parameters (USB\_nHCCPARAMS)

This register identifies multiple mode control (time-base bit functionality), addressing capability.

Address: 402E\_0000h base + 108h offset + (512d × i), where i=0d to 1d

**USB\_nHCCPARAMS field descriptions**

Field	Description
31–16 -	This field is reserved. Reserved
15–8 EECP	EHCI Extended Capabilities Pointer.  This field indicates the existence of a capabilities list. A value of 00h indicates no extended capabilities are implemented. A non-zero value in this register indicates the offset in PCI configuration space of the first EHCI extended capability. The pointer value must be 40h or greater if implemented to maintain the consistency of the PCI header defined for this class of device.  <b>NOTE:</b> These bits are set '00h' in all controller core.
7–4 IST	Isochronous Scheduling Threshold.  This field indicates, relative to the current position of the executing host controller, where software can reliably update the isochronous schedule. When bit [7] is zero, the value of the least significant 3 bits indicates the number of micro-frames a host controller can hold a set of isochronous data structures (one or more) before flushing the state. When bit [7] is a one, then host software assumes the host controller may cache an isochronous data structure for an entire frame.  These bits are set '00h' in all controller core.
3 -	This field is reserved. Reserved

Table continues on the next page...

**USB\_nHCCPARAMS field descriptions (continued)**

Field	Description
2 ASP	<p>Asynchronous Schedule Park Capability</p> <p>If this bit is set to a one, then the host controller supports the park feature for high-speed queue heads in the Asynchronous Schedule. The feature can be disabled or enabled and set to a specific level by using the <i>Asynchronous Schedule Park Mode Enable</i> and <i>Asynchronous Schedule Park Mode Count</i> fields in the USBCMD register.</p> <p><b>NOTE:</b> ASP bit reset value: '00b' for OTG controller core, '11b' for Host-only controller core.</p>
1 PFL	<p>Programmable Frame List Flag</p> <p>If this bit is set to zero, then the system software must use a frame list length of 1024 elements with this host controller. The USBCMD register Frame List Size field is a read-only register and must be set to zero.</p> <p>If set to a one, then the system software can specify and use a smaller frame list and configure the host controller via the USBCMD register Frame List Size field. The frame list must always be aligned on a 4K-page boundary. This requirement ensures that the frame list is always physically contiguous.</p> <p>This bit is set '1b' in all controller core.</p>
0 ADC	<p>64-bit Addressing Capability</p> <p>This bit is set '0b' in all controller core, no 64-bit addressing capability is supported.</p>

**41.7.16 Device Controller Interface Version (USB\_nDCIVERSION)**

This register indicates the two-byte BCD encoding of the device controller interface version number.

Address: 402E\_0000h base + 120h offset + (512d × i), where i=0d to 1d

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### USB\_nDCCPARAMS field descriptions

Field	Description
31–9 -	This field is reserved. Reserved
8 HC	Host Capable When this bit is 1, this controller is capable of operating as an EHCI compatible USB 2.0 host controller.
7 DC	Device Capable When this bit is 1, this controller is capable of operating as a USB 2.0 device.
6–5 -	This field is reserved. Reserved
DEN	Device Endpoint Number This field indicates the number of endpoints built into the device controller. If this controller is not device capable, then this field will be zero. Valid values are 0 - 15.

### 41.7.18 USB Command Register (USB\_nUSBCMD)

The Command Register indicates the command to be executed by the serial bus host/device controller. Writing to the register causes a command to be executed.

Address: 402E\_0000h base + 140h offset + (512d × i), where i=0d to 1d

**USB\_nUSBCMD field descriptions**

Field	Description
31–24 -	This field is reserved. Reserved
23–16 ITC	Interrupt Threshold Control -Read/Write. The system software uses this field to set the maximum rate at which the host/device controller will issue interrupts. ITC contains the maximum interrupt interval measured in micro-frames. Valid values are shown below. Value Maximum Interrupt Interval 0x00 Immediate (no threshold) 0x01 1 micro-frame 0x02 2 micro-frames 0x04 4 micro-frames 0x08 8 micro-frames 0x10 16 micro-frames

## USB\_nUSBCMD field descriptions (continued)

Field	Description
	0x20 32 micro-frames 0x40 64 micro-frames
15 FS_2	<p>Frame List Size - (Read/Write or Read Only). [host mode only]</p> <p>This field is Read/Write only if Programmable Frame List Flag in the HCCPARAMS registers is set to one. This field specifies the size of the frame list that controls which bits in the Frame Index Register should be used for the Frame List Current index.</p> <p><b>NOTE:</b> This field is made up from USBCMD bits 15, 3 and 2.</p> <p>Value Meaning</p> <p>000 1024 elements (4096 bytes) Default value 001 512 elements (2048 bytes) 010 256 elements (1024 bytes) 011 128 elements (512 bytes) 100 64 elements (256 bytes) 101 32 elements (128 bytes) 110 16 elements (64 bytes) 111 8 elements (32 bytes)</p>
14 ATDTW	<p>Add dTD TripWire - Read/Write. [device mode only]</p> <p>This bit is used as a semaphore to ensure proper addition of a new dTD to an active (primed) endpoint's linked list. This bit is set and cleared by software.</p> <p>This bit would also be cleared by hardware when state machine is hazard region for which adding a dTD to a primed endpoint may go unrecognized.</p>
13 SUTW	<p>Setup TripWire - Read/Write. [device mode only]</p> <p>This bit is used as a semaphore to ensure that the setup data payload of 8 bytes is extracted from a QH by the DCD without being corrupted. If the setup lockout mode is off (SLOM bit in USB core register n_USBMODE, see <a href="#">USB Device Mode (USB_nUSBMODE)</a> ) then there is a hazard when new setup data arrives while the DCD is copying the setup data payload from the QH for a previous setup packet. This bit is set and cleared by software.</p> <p>This bit would also be cleared by hardware when a hazard detected.</p>
12 -	This field is reserved. Reserved
11 ASPE	<p>Asynchronous Schedule Park Mode Enable - Read/Write.</p> <p>If the <i>Asynchronous Park Capability</i> bit in the HCCPARAMS register is a one, then this bit defaults to a 1h and is R/W. Otherwise the bit must be a zero and is RO. Software uses this bit to enable or disable Park mode. When this bit is one, Park mode is enabled. When this bit is a zero, Park mode is disabled.</p> <p><b>NOTE:</b> ASPE bit reset value: '0b' for OTG controller .</p>
10 -	This field is reserved. Reserved
9-8 ASP	<p>Asynchronous Schedule Park Mode Count - Read/Write.</p> <p>If the <i>Asynchronous Park Capability</i> bit in the HCCPARAMS register is a one, then this field defaults to 3h and is R/W. Otherwise it defaults to zero and is Read-Only. It contains a count of the number of successive transactions the host controller is allowed to execute from a high-speed queue head on the</p>

Table continues on the next page...

**USB\_nUSBCMD field descriptions (continued)**

Field	Description
	Asynchronous schedule before continuing traversal of the Asynchronous schedule. Valid values are 1h to 3h. Software must not write a zero to this bit when <i>Park Mode Enable</i> is a one as this will result in undefined behavior.  This field is set to 3h in all controller core.
7 -	This field is reserved. Reserved
6 IAA	Interrupt on Async Advance Doorbell - Read/Write.  This bit is used as a doorbell by software to tell the host controller to issue an interrupt the next time it advances asynchronous schedule. Software must write a 1 to this bit to ring the doorbell.  When the host controller has evicted all appropriate cached schedule states, it sets the Interrupt on Async Advance status bit in the USBSTS register. If the Interrupt on Sync Advance Enable bit in the USBINTR register is one, then the host controller will assert an interrupt at the next interrupt threshold.  The host controller sets this bit to zero after it has set the Interrupt on Sync Advance status bit in the USBSTS register to one. Software should not write a one to this bit when the asynchronous schedule is inactive. Doing so will yield undefined results.  This bit is only used in host mode. Writing a one to this bit when device mode is selected will have undefined results.
5 ASE	Asynchronous Schedule Enable - Read/Write. Default 0b.  This bit controls whether the host controller skips processing the Asynchronous Schedule.  Only the host controller uses this bit.  Values Meaning  0 Do not process the Asynchronous Schedule. 1 Use the ASYNCLISTADDR register to access the Asynchronous Schedule.
4 PSE	Periodic Schedule Enable- Read/Write. Default 0b.  This bit controls whether the host controller skips processing the Periodic Schedule.  Only the host controller uses this bit.  Values Meaning  0 Do not process the Periodic Schedule 1 Use the PERIODICLISTBASE register to access the Periodic Schedule.
3-2 FS_1	See description at bit 15
1 RST	Controller Reset (RESET) - Read/Write. Software uses this bit to reset the controller. This bit is set to zero by the Host/Device Controller when the reset process is complete. Software cannot terminate the reset process early by writing a zero to this register.  Host operation mode:  When software writes a one to this bit, the Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Any transaction currently in progress on USB is immediately terminated. A USB reset is not driven on downstream ports. Software should not set this bit to a one when the HCHalted bit in the USBSTS register is a zero. Attempting to reset an actively running host controller will result in undefined behavior.  Device operation mode:

*Table continues on the next page...*

## USB\_nUSBCMD field descriptions (continued)

Field	Description
	<p>When software writes a one to this bit, the Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Writing a one to this bit when the device is in the attached state is not recommended, because the effect on an attached host is undefined. In order to ensure that the device is not in an attached state before initiating a device controller reset, all primed endpoints should be flushed and the USBCMD Run/Stop bit should be set to 0.</p>
<p>0 RS</p>	<p>Run/Stop (RS) - Read/Write. Default 0b. 1=Run. 0=Stop.</p> <p>Host operation mode:</p> <p>When set to '1b', the Controller proceeds with the execution of the schedule. The Controller continues execution as long as this bit is set to a one. When this bit is set to 0, the Host Controller completes the current transaction on the USB and then halts. The HC Halted bit in the status register indicates when the Controller has finished the transaction and has entered the stopped state. Software should not write a one to this field unless the controller is in the Halted state (that is, HCHalted in the USBSTS register is a one).</p> <p>Device operation mode:</p> <p>Writing a one to this bit will cause the controller to enable a pull-up on D+ and initiate an attach event. This control bit is not directly connected to the pull-up enable, as the pull-up will become disabled upon transitioning into high-speed mode. Software should use this bit to prevent an attach event before the controller has been properly initialized. Writing a 0 to this will cause a detach event.</p>

### 41.7.19 USB Status Register (USB\_nUSBSTS)

This register indicates various states of the Host/Device Controller and any pending interrupts. This register does not indicate status resulting from a transaction on the serial bus.

Address: 402E\_0000h base + 144h offset + (512d × i), where i=0d to 1d

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### USB\_nUSBSTS field descriptions

Field	Description
31–26 -	This field is reserved. Reserved
25 TI1	General Purpose Timer Interrupt 1(GPTINT1)--R/WC. This bit is set when the counter in the GPTIMER1CTRL register transitions to zero, writing a one to this bit will clear it.
24 TI0	General Purpose Timer Interrupt 0(GPTINT0)--R/WC. This bit is set when the counter in the GPTIMER0CTRL register transitions to zero, writing a one to this bit clears it.
23–17 -	This field is reserved. Reserved
16 NAKI	NAK Interrupt Bit--RO. This bit is set by hardware when for a particular endpoint both the TX/RX Endpoint NAK bit and corresponding TX/RX Endpoint NAK Enable bit are set. This bit is automatically cleared by hardware when all Enabled TX/RX Endpoint NAK bits are cleared.
15 AS	Asynchronous Schedule Status - Read Only. This bit reports the current real status of the Asynchronous Schedule. When set to zero the asynchronous schedule status is disabled and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Asynchronous Schedule when software transitions the Asynchronous Schedule Enable bit in the USBCMD register. When this bit and the Asynchronous Schedule Enable bit are the same value, the Asynchronous Schedule is either enabled (1) or disabled (0). Only used in the host operation mode.
14 PS	Periodic Schedule Status - Read Only.

Table continues on the next page...

**USB\_nUSBSTS field descriptions (continued)**

Field	Description
	<p>This bit reports the current real status of the Periodic Schedule. When set to zero the periodic schedule is disabled, and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Periodic Schedule when software transitions the Periodic Schedule Enable bit in the USBCMD register. When this bit and the Periodic Schedule Enable bit are the same value, the Periodic Schedule is either enabled (1) or disabled (0).</p> <p>Only used in the host operation mode.</p>
13 RCL	<p>Reclamation - Read Only.</p> <p>This is a read-only status bit used to detect an empty asynchronous schedule.</p> <p>Only used in the host operation mode.</p>
12 HCH	<p>HCHalted - Read Only.</p> <p>This bit is a zero whenever the Run/Stop bit is a one. The Controller sets this bit to one after it has stopped executing because of the Run/Stop bit being set to 0, either by software or by the Controller hardware (for example, an internal error).</p> <p>Only used in the host operation mode.</p> <p>Default value is '0b' for OTG core.</p> <p>This is because OTG core is not operating as host in default. Please see CM bit in USB_n_USBMODE register.</p> <p><b>NOTE:</b> HCH bit reset value: '0b' for OTG controller core.</p>
11 -	<p>This field is reserved.</p> <p>Reserved</p>
10 ULPII	<p>ULPI Interrupt - R/WC.</p> <p>This bit will be set '1b' by hardware when there is an event completion in ULPI viewport.</p> <p>This bit is usable only if the controller support UPLI interface mode.</p>
9 -	<p>This field is reserved.</p> <p>Reserved</p>
8 SLI	<p>DCSuspend - R/WC.</p> <p>When a controller enters a suspend state from an active state, this bit will be set to a one. The device controller clears the bit upon exiting from a suspend state.</p> <p>Only used in device operation mode.</p>
7 SRI	<p>SOF Received - R/WC.</p> <p>When the device controller detects a Start Of (micro) Frame, this bit will be set to a one. When a SOF is extremely late, the device controller will automatically set this bit to indicate that an SOF was expected. Therefore, this bit will be set roughly every 1ms in device FS mode and every 125ms in HS mode and will be synchronized to the actual SOF that is received.</p> <p>Because the device controller is initialized to FS before connect, this bit will be set at an interval of 1ms during the prelude to connect and chirp.</p> <p>In host mode, this bit will be set every 125us and can be used by host controller driver as a time base.</p> <p>Software writes a 1 to this bit to clear it.</p>
6 URI	<p>USB Reset Received - R/WC.</p> <p>When the device controller detects a USB Reset and enters the default state, this bit will be set to a one. Software can write a 1 to this bit to clear the USB Reset Received status bit.</p> <p>Only used in device operation mode.</p>

*Table continues on the next page...*

## USB\_nUSBSTS field descriptions (continued)

Field	Description
5 AAI	<p>Interrupt on Async Advance - R/WC.</p> <p>System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing a one to the Interrupt on Async Advance Doorbell bit in the n_USBCMD register. This status bit indicates the assertion of that interrupt source.</p> <p>Only used in host operation mode.</p>
4 SEI	<p>System Error- R/WC.</p> <p>This bit is will be set to '1b' when an Error response is seen to a read on the system interface.</p>
3 FRI	<p>Frame List Rollover - R/WC.</p> <p>The Host Controller sets this bit to a one when the Frame List Index rolls over from its maximum value to zero. The exact value at which the rollover occurs depends on the frame list size. For example. If the frame list size (as programmed in the Frame List Size field of the USB_n_USBCMD register) is 1024, the Frame Index Register rolls over every time FRINDEX [13] toggles. Similarly, if the size is 512, the Host Controller sets this bit to a one every time FHINDEX [12] toggles.</p> <p>Only used in host operation mode.</p>
2 PCI	<p>Port Change Detect - R/WC.</p> <p>The Host Controller sets this bit to a one when on any port a Connect Status occurs, a Port Enable/Disable Change occurs, or the Force Port Resume bit is set as the result of a J-K transition on the suspended port.</p> <p>The Device Controller sets this bit to a one when the port controller enters the full or high-speed operational state. When the port controller exits the full or high-speed operation states due to Reset or Suspend events, the notification mechanisms are the USB Reset Received bit and the DCSuspend bits respectively.</p>
1 UEI	<p>USB Error Interrupt (USBERRINT) - R/WC.</p> <p>When completion of a USB transaction results in an error condition, this bit is set by the Host/Device Controller. This bit is set along with the USBINT bit, if the TD on which the error interrupt occurred also had its interrupt on complete (IOC) bit set.</p> <p>The device controller detects resume signaling only.</p>
0 UI	<p>USB Interrupt (USBINT) - R/WC.</p> <p>This bit is set by the Host/Device Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) has an interrupt on complete (IOC) bit set.</p> <p>This bit is also set by the Host/Device Controller when a short packet is detected. A short packet is when the actual number of bytes received was less than the expected number of bytes.</p>

### 41.7.20 Interrupt Enable Register (USB\_nUSBINTR)

The interrupts to software are enabled with this register. An interrupt is generated when a bit is set and the corresponding interrupt source is active. The USB Status register (n\_USBSTS) still shows interrupt sources even if they are disabled by the n\_USBINTR register, allowing polling of interrupt events by the software.

Address: 402E\_0000h base + 148h offset + (512d × i), where i=0d to 1d

**USB\_nUSBINTR field descriptions**

Field	Description
31–26 -	This field is reserved. Reserved
25 TIE1	General Purpose Timer #1 Interrupt Enable When this bit is one and the TI1 bit in n_USBSTS register is a one the controller will issue an interrupt.
24 TIE0	General Purpose Timer #0 Interrupt Enable When this bit is one and the TI0 bit in n_USBSTS register is a one the controller will issue an interrupt.
23–20 -	This field is reserved. Reserved
19 UPIE	USB Host Periodic Interrupt Enable

Table continues on the next page...

**USB\_nUSBINTR field descriptions (continued)**

Field	Description
	When this bit is one, and the UPI bit in the n_USBSTS register is one, host controller will issue an interrupt at the next interrupt threshold.
18 UAIE	USB Host Asynchronous Interrupt Enable When this bit is one, and the UAI bit in the n_USBSTS register is one, host controller will issue an interrupt at the next interrupt threshold.
17 -	This field is reserved. Reserved
16 NAKE	NAK Interrupt Enable When this bit is one and the NAKI bit in n_USBSTS register is a one the controller will issue an interrupt.
15–11 -	These bits are reserved and should be set to zero.
10 ULPIE	ULPI Interrupt Enable When this bit is one and the UPLI bit in n_USBSTS register is a one the controller will issue an interrupt. This bit is usable only if the controller support UPLI interface mode.
9 -	This field is reserved. Reserved
8 SLE	Sleep Interrupt Enable When this bit is one and the SLI bit in n_n_USBSTS register is a one the controller will issue an interrupt. Only used in device operation mode.
7 SRE	SOF Received Interrupt Enable When this bit is one and the SRI bit in n_USBSTS register is a one the controller will issue an interrupt.
6 URE	USB Reset Interrupt Enable When this bit is one and the URI bit in n_USBSTS register is a one the controller will issue an interrupt. Only used in device operation mode.
5 AAE	Async Advance Interrupt Enable When this bit is one and the AAI bit in n_USBSTS register is a one the controller will issue an interrupt. Only used in host operation mode.
4 SEE	System Error Interrupt Enable When this bit is one and the SEI bit in n_USBSTS register is a one the controller will issue an interrupt. Only used in host operation mode.
3 FRE	Frame List Rollover Interrupt Enable When this bit is one and the FRI bit in n_USBSTS register is a one the controller will issue an interrupt. Only used in host operation mode.
2 PCE	Port Change Detect Interrupt Enable When this bit is one and the PCI bit in n_USBSTS register is a one the controller will issue an interrupt.
1 UEE	USB Error Interrupt Enable When this bit is one and the UEI bit in n_USBSTS register is a one the controller will issue an interrupt.
0 UE	USB Interrupt Enable When this bit is one and the UI bit in n_USBSTS register is a one the controller will issue an interrupt.

### 41.7.21 USB Frame Index (USB\_nFRINDEX)

This register is used by the host controller to index the periodic frame list. The register updates every 125 microseconds (once each micro-frame). Bits [N: 3] are used to select a particular entry in the Periodic Frame List during periodic schedule execution. The number of bits used for the index depends on the size of the frame list as set by system software in the Frame List Size field in the n\_USBCMD register.

This register must be written as a DWord. Byte writes produce undefined results. This register cannot be written unless the Host Controller is in the 'Halted' state as indicated by the HCHalted bit. A write to this register while the Run/Stop bit is set to a one produces undefined results. Writes to this register also affect the SOF value.

In device mode this register is read only and, the device controller updates the FRINDEX [13:3] register from the frame number indicated by the SOF marker. Whenever a SOF is received by the USB bus, FRINDEX [13:3] will be checked against the SOF marker. If FRINDEX [13:3] is different from the SOF marker, FRINDEX [13:3] will be set to the SOF value and FRINDEX [2:0] will be set to zero (that is, SOF for 1 ms frame). If FRINDEX [13:3] is equal to the SOF value, FRINDEX [2:0] will be increment (that is, SOF for 125 us micro-frame.).

Address: 402E\_0000h base + 14Ch offset + (512d × i), where i=0d to 1d

## 41.7.22 Frame List Base Address (USB\_nPERIODICLISTBASE)

Host Controller only

This 32-bit register contains the beginning address of the Periodic Frame List in the system memory. HCD loads this register prior to starting the schedule execution by the Host Controller. The memory structure referenced by this physical memory pointer is assumed to be 4-Kbyte aligned. The contents of this register are combined with the Frame Index Register (USB\_n\_FRINDEX) to enable the Host Controller to step through the Periodic Frame List in sequence.

Address: 402E\_0000h base + 154h offset + (512d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### USB\_nDEVICEADDR field descriptions

Field	Description
31–25 USBADR	Device Address. These bits correspond to the USB device address
24 USBADRA	Device Address Advance. Default=0. When this bit is '0', any writes to USBADR are instantaneous. When this bit is written to a '1' at the same time or before USBADR is written, the write to the USBADR field is staged and held in a hidden register. After an IN occurs on endpoint 0 and is ACKed, USBADR will be loaded from the holding register. Hardware will automatically clear this bit on the following conditions: 1) IN is ACKed to endpoint 0. (USBADR is updated from staging register). 2) OUT/SETUP occur to endpoint 0. (USBADR is not updated). 3) Device Reset occurs (USBADR is reset to 0). <b>NOTE:</b> After the status phase of the SET_ADDRESS descriptor, the DCD has 2 ms to program the USBADR field. This mechanism will ensure this specification is met when the DCD can not write of the device address within 2ms from the SET_ADDRESS status phase. If the DCD writes the USBADR with USBADRA=1 after the SET_ADDRESS data phase (before the prime of the status phase), the USBADR will be programmed instantly at the correct time and meet the 2ms USB requirement.
-	This field is reserved. Reserved

## 41.7.24 Next Asynch. Address (USB\_nASYNCLISTADDR)

Host Controller only

This 32-bit register contains the address of the next asynchronous queue head to be executed by the host. Bits [4:0] of this register cannot be modified by the system software and will always return a zero when read.

Address: 402E\_0000h base + 158h offset + (512d × i), where i=0d to 1d

**USB\_nASYNCLISTADDR field descriptions**

Field	Description
31–5 ASYBASE	Link Pointer Low (LPL). These bits correspond to memory address signals [31:5], respectively. This field may only reference a Queue Head (QH). Only used by the host controller.
-	This field is reserved. Reserved

**41.7.25 Endpoint List Address (USB\_nENDPTLISTADDR)**

Device Controller only

In device mode, this register contains the address of the top of the endpoint list in system memory. Bits [10:0] of this register cannot be modified by the system software and will always return a zero when read.

The memory structure referenced by this physical memory pointer is assumed 64-byte.

Address: 402E\_0000h base + 158h offset + (512d × i), where i=0d to 1d

**USB\_nENDPTLISTADDR field descriptions**

Field	Description
31–11 EPBASE	Endpoint List Pointer(Low). These bits correspond to memory address signals [31:11], respectively. This field will reference a list of up to 32 Queue Head (QH) (that is, one queue head per endpoint & direction).
-	This field is reserved. Reserved

**41.7.26 Programmable Burst Size (USB\_nBURSTSIZE)**

This register is used to control the burst size used during data movement on the AHB master interface. This register is ignored if AHBBRST bits in SBUSCFG register is non-zero value.

## USB Core Memory Map/Register Definition

Address: 402E\_0000h base + 160h offset + (512d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### USB\_nBURSTSIZE field descriptions

Field	Description
31–17 -	This field is reserved. Reserved
16–8 TXPBURST	Programmable TX Burst Size. Default value is determined by TXBURST bits in n_HWTXBUF. This register represents the maximum length of a the burst in 32-bit words while moving data from system memory to the USB bus.
RXPBURST	Programmable RX Burst Size. Default value is determined by TXBURST bits in n_HWRXBUF. This register represents the maximum length of a the burst in 32-bit words while moving data from the USB bus to system memory.

## 41.7.27 TX FIFO Fill Tuning (USB\_nTXFILLTUNING)

The fields in this register control performance tuning associated with how the host controller posts data to the TX latency FIFO before moving the data onto the USB bus. The specific areas of performance include the how much data to post into the FIFO and an estimate for how long that operation should take in the target system.

Definitions:

$T_0$  = Standard packet overhead

$T_1$  = Time to send data payload

$T_{ff}$  = Time to fetch packet into TX FIFO up to specified level.

$T_s$  = Total Packet Flight Time (send-only) packet

$T_s = T_0 + T_1$

$T_p$  = Total Packet Time (fetch and send) packet

$T_p = T_{ff} + T_0 + T_1$

Upon discovery of a transmit (OUT/SETUP) packet in the data structures, host controller checks to ensure  $T_p$  remains before the end of the [micro]frame. If so it proceeds to pre-fill the TX FIFO. If at anytime during the pre-fill operation the time remaining the [micro]frame is  $< T_s$  then the packet attempt ceases and the packet is tried at a later time. Although this is not an error condition and the host controller will eventually recover, a

mark will be made the scheduler health counter to note the occurrence of a "back-off" event. When a back-off event is detected, the partial packet fetched may need to be discarded from the latency buffer to make room for periodic traffic that will begin after the next SOF. Too many back-off events can waste bandwidth and power on the system bus and thus should be minimized (not necessarily eliminated). Back-offs can be minimized with use of the `n_TSCHHEALTH` ( $T_{ff}$ ) described below.

### NOTE

The reset value could vary from instance to instance. Please see the detail in bit field description and ignore reset value in summary table in this case!

Address: `402E_0000h base + 164h offset + (512d × i)`, where  $i=0d$  to  $1d$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																																
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### USB\_nTXFILLTUNING field descriptions

Field	Description
31–22 -	This field is reserved. Reserved
21–16 TXFIFOTHRES	FIFO Burst Threshold. (Read/Write) This register controls the number of data bursts that are posted to the TX latency FIFO in host mode before the packet begins on to the bus. The minimum value is 2 and this value should be a low as possible to maximize USB performance. A higher value can be used in systems with unpredictable latency and/or insufficient bandwidth where the FIFO may underrun because the data transferred from the latency FIFO to USB occurs before it can be replenished from system memory. This value is ignored if the Stream Disable bit in <code>USB_n_USBMODE</code> register is set. Default value is '0Ah' for OTG controller core.
15–13 -	This field is reserved. Reserved
12–8 TXSCHHEALTH	Scheduler Health Counter. (Read/Write To Clear) This register increments when the host controller fails to fill the TX latency FIFO to the level programmed by <code>TXFIFOTHRES</code> before running out of time to send the packet before the next Start-Of-Frame. This health counter measures the number of times this occurs to provide feedback to selecting a proper <code>TXSCHOH</code> . Writing to this register will clear the counter and this counter will max. at 31. Default value is '00h' for OTG controller core.
TXSCHOH	Scheduler Overhead. (Read/Write) [Default = 0] This register adds an additional fixed offset to the schedule time estimator described above as $T_{ff}$ . As an approximation, the value chosen for this register should limit the number of back-off events captured in the <code>TXSCHHEALTH</code> to less than 10 per second in a highly utilized bus. Choosing a value that is too high for this register is not desired as it can needlessly reduce USB utilization. The time unit represented in this register is 1.267us when a device is connected in High-Speed Mode. The time unit represented in this register is 6.333us when a device is connected in Low/Full Speed Mode. Default value is '08h' for OTG controller core.

### 41.7.28 Endpoint NAK (USB\_nENDPTNAK)

Address: 402E\_0000h base + 178h offset + (512d × i), where i=0d to 1d

#### USB\_nENDPTNAK field descriptions

Field	Description
31–24 -	This field is reserved. Reserved
23–16 EPTN	TX Endpoint NAK - R/WC. Each TX endpoint has 1 bit in this field. The bit is set when the device sends a NAK handshake on a received IN token for the corresponding endpoint. Bit [N] - Endpoint #[N], N is 0-7
15–8 -	This field is reserved. Reserved
EPRN	RX Endpoint NAK - R/WC. Each RX endpoint has 1 bit in this field. The bit is set when the device sends a NAK handshake on a received OUT or PING token for the corresponding endpoint. Bit [N] - Endpoint #[N], N is 0-7

### 41.7.29 Endpoint NAK Enable (USB\_nENDPTNAKEN)

Address: 402E\_0000h base + 17Ch offset + (512d × i), where i=0d to 1d

#### USB\_nENDPTNAKEN field descriptions

Field	Description
31–24 -	This field is reserved. Reserved
23–16 EPTNE	TX Endpoint NAK Enable - R/W. Each bit is an enable bit for the corresponding TX Endpoint NAK bit. If this bit is set and the corresponding TX Endpoint NAK bit is set, the NAK Interrupt bit is set. Bit [N] - Endpoint #[N], N is 0-7
15–8 -	This field is reserved. Reserved
EPRNE	RX Endpoint NAK Enable - R/W.

Table continues on the next page...

## USB\_nENDPTNAKEN field descriptions (continued)

Field	Description
	Each bit is an enable bit for the corresponding RX Endpoint NAK bit. If this bit is set and the corresponding RX Endpoint NAK bit is set, the NAK Interrupt bit is set. Bit [N] - Endpoint #[N], N is 0-7

## 41.7.30 Configure Flag Register (USB\_nCONFIGFLAG)

Address: 402E\_0000h base + 180h offset + (512d × i), where i=0d to 1d

## USB\_nCONFIGFLAG field descriptions

Field	Description
31–1 -	This field is reserved. Reserved
0 CF	Configure Flag Host software sets this bit as the last action in its process of configuring the Host Controller. This bit controls the default port-routing control logic.  0 Port routing control logic default-routes each port to an implementation dependent classic host controller. 1 Port routing control logic default-routes all ports to this host controller.

## 41.7.31 Port Status &amp; Control (USB\_nPORTSC1)

## Host Controller

A host controller could implement one to eight port status and control registers. The number is determined by N\_PORTs bits in HWSPARAMs register (please see [Host Controller Structural Parameters \(USB\\_nHCSPARAMS\)](#)). Software could read this parameter register to determine how many ports need service.

All controller cores on this product are Single-Port, so there is only one port status and control register for each controller core.

This register is only reset by power on reset or controller core reset. The initial conditions of a port are:

- No device connected
- Port disabled

If the port supports power control, this state remains until port power is supplied (by software).

Device Controller

A controller operating in device mode has only port register one (PORTSC1) and it does not support power control in that mode. Port control in device mode is only used for status port reset, suspend, and current connect status. It is also used to initiate test mode or force signaling and allows software to put the PHY into low power suspend mode and disable the PHY clock.

Address: 402E\_0000h base + 184h offset + (512d × i), where i=0d to 1d

## USB\_nPORTSC1 field descriptions

Field	Description
31–30 PTS_1	<b>NOTE:</b> All USB port interface modes are listed in this field description, but not all are supported. For detail feature of each controller core, please see <a href="#">Features</a> . The behaviour is unknown when unsupported interface mode is selected.
29 STS	Serial Transceiver Select 1 Serial Interface Engine is selected 0 Parallel Interface signals is selected Serial Interface Engine can be used in combination with UTMI+/ULPI physical interface to provide FS/LS signaling instead of the parallel interface signals. When this bit is set '1b', serial interface engine will be used instead of parallel interface signals. This bit has no effect unless PTS bits is set to select UTMI+/ULPI interface. The Serial/USB1.1 PHY/IC-USB will use the serial interface engine for FS/LS signaling regardless of this bit value.
28 PTW	Parallel Transceiver Width This bit has no effect if serial interface engine is used. For OTG1/OTG2 core, it is Read-Only. Reset value is '1b'. 0 Select the 8-bit UTMI interface [60MHz] 1 Select the 16-bit UTMI interface [30MHz]
27–26 PSPD	Port Speed - Read Only. This register field indicates the speed at which the port is operating. 00 Full Speed 01 Low Speed 10 High Speed 11 Undefined
25 PTS_2	See description at bits 31-30
24 PFSC	Port Force Full Speed Connect - Read/Write. Default = 0b. When this bit is set to '1b', the port will be forced to only connect at Full Speed, It disables the chirp sequence that allows the port to identify itself as High Speed. 1 Forced to full speed 0 Normal operation
23 PHCD	PHY Low Power Suspend - Clock Disable (PLPSCD) - Read/Write. Default = 0b. When this bit is set to '1b', the PHY clock is disabled. Reading this bit will indicate the status of the PHY clock. <b>NOTE:</b> The PHY clock cannot be disabled if it is being used as the system clock. In device mode, The PHY can be put into Low Power Suspend when the device is not running (USBCMD Run/Stop=0b) or the host has signalled suspend (PORTSC1 SUSPEND=1b). PHY Low power suspend will be cleared automatically when the host initials resume. Before forcing a resume from the device, the device controller driver must clear this bit. In host mode, the PHY can be put into Low Power Suspend when the downstream device has been put into suspend mode or when no downstream device is connected. Low power suspend is completely under the control of software.

*Table continues on the next page...*

**USB\_nPORTSC1 field descriptions (continued)**

Field	Description
	1 Disable PHY clock 0 Enable PHY clock
22 WKOC	Wake on Over-current Enable (WKOC_E) - Read/Write. Default = 0b. Writing this bit to a one enables the port to be sensitive to over-current conditions as wake-up events. This field is zero if <i>Port Power</i> ( <a href="#">Port Status &amp; Control (USB_nPORTSC1)</a> ) is zero.
21 WKDC	Wake on Disconnect Enable (WKDCNNT_E) - Read/Write. Default=0b. Writing this bit to a one enables the port to be sensitive to device disconnects as wake-up events. This field is zero if <i>Port Power</i> ( <a href="#">Port Status &amp; Control (USB_nPORTSC1)</a> ) is zero or in device mode.
20 WKCEN	Wake on Connect Enable (WKCENNT_E) - Read/Write. Default=0b. Writing this bit to a one enables the port to be sensitive to device connects as wake-up events. This field is zero if <i>Port Power</i> ( <a href="#">Port Status &amp; Control (USB_nPORTSC1)</a> ) is zero or in device mode.
19–16 PTC	Port Test Control - Read/Write. Default = 0000b. Refer to <a href="#">Port Test Mode</a> for the operational model for using these test modes and the USB Specification Revision 2.0, Chapter 7 for details on each test mode.  The FORCE_ENABLE_FS and FORCE_ENABLE_LS are extensions to the test mode support specified in the EHCI specification. Writing the PTC field to any of the FORCE_ENABLE_{HS/FS/LS} values will force the port into the connected and enabled state at the selected speed. Writing the PTC field back to TEST_MODE_DISABLE will allow the port state machines to progress normally from that point.  <b>NOTE:</b> <i>Low speed operations are not supported as a peripheral device.</i> Any other value than zero indicates that the port is operating in test mode.  Value Specific Test  0000 TEST_MODE_DISABLE 0001 J_STATE 0010 K_STATE 0011 SE0 (host) / NAK (device) 0100 Packet 0101 FORCE_ENABLE_HS 0110 FORCE_ENABLE_FS 0111 FORCE_ENABLE_LS 1000-1111 Reserved
15–14 PIC	Port Indicator Control - Read/Write. Default = 0b. Writing to this field has no effect if the P_INDICATOR bit in the HCSPARAMS register is a zero. Refer to the USB Specification Revision 2.0 for a description on how these bits are to be used. This field is zero if <i>Port Power</i> is zero.  Bit Value Meaning  00 Port indicators are off 01 Amber 10 Green 11 Undefined
13 PO	Port Owner-Read/Write. Default = 0.

*Table continues on the next page...*

## USB\_nPORTSC1 field descriptions (continued)

Field	Description
	<p>This bit unconditionally goes to a 0 when the configured bit in the CONFIGFLAG register makes a 0 to 1 transition. This bit unconditionally goes to 1 whenever the Configured bit is zero. System software uses this field to release ownership of the port to a selected host controller (in the event that the attached device is not a high-speed device). Software writes a one to this bit when the attached device is not a high-speed device. A one in this bit means that an internal companion controller owns and controls the port.</p> <p>Port owner handoff is not supported in all controller cores, therefore this bit will always be 0.</p>
12 PP	<p>Port Power (PP)-Read/Write or Read Only.</p> <p>The function of this bit depends on the value of the Port Power Switching (PPC) field in the HCSPARAMS register. The behavior is as follows:</p> <p>PPC</p> <p>PP Operation</p> <p>0</p> <p>1b <i>Read Only</i> - Host controller does not have port power control switches. Each port is hard-wired to power.</p> <p>1</p> <p>1b/0b - <i>Read/Write</i>. OTG controller requires port power control switches. This bit represents the current setting of the switch (0=off, 1=on). When power is not available on a port (that is, PP equals a 0), the port is non-functional and will not report attaches, detaches, etc.</p> <p>When an over-current condition is detected on a powered port and PPC is a one, the PP bit in each affected port may be transitional by the host controller driver from a one to a zero (removing power from the port).</p> <p>This feature is implemented in all controller cores (PPC = 1).</p>
11–10 LS	<p>Line Status-Read Only. These bits reflect the current logical levels of the D+ (bit 11) and D- (bit 10) signal lines.</p> <p>In host mode, the use of linestate by the host controller driver is not necessary (unlike EHCI), because the port controller state machine and the port routing manage the connection of LS and FS.</p> <p>In device mode, the use of linestate by the device controller driver is not necessary.</p> <p>The encoding of the bits are:</p> <p>Bits [11:10] Meaning</p> <p>00 SE0</p> <p>10 J-state</p> <p>01 K-state</p> <p>11 Undefined</p>
9 HSP	<p>High-Speed Port - Read Only. Default = 0b.</p> <p>When the bit is one, the host/device connected to the port is in high-speed mode and if set to zero, the host/device connected to the port is not in a high-speed mode.</p> <p><b>NOTE:</b> HSP is redundant with PSPD(bit 27, 26) but remained for compatibility.</p>
8 PR	<p>Port Reset - Read/Write or Read Only. Default = 0b.</p> <p>In Host Mode: Read/Write. 1=Port is in Reset. 0=Port is not in Reset. Default 0.</p> <p>When software writes a one to this bit the bus-reset sequence as defined in the USB Specification Revision 2.0 is started. <i>This bit will automatically change to zero after the reset sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the reset duration is timed in the driver.</i></p>

Table continues on the next page...

**USB\_nPORTSC1 field descriptions (continued)**

Field	Description
	<p>In Device Mode: This bit is a read only status bit. Device reset from the USB bus is also indicated in the USBSTS register.</p> <p>This field is zero if <i>Port Power</i>(<a href="#">Port Status &amp; Control (USB_nPORTSC1)</a>) is zero.</p>
<p>7 SUSP</p>	<p>Suspend - Read/Write or Read Only. Default = 0b.</p> <p>1=Port in suspend state. 0=Port not in suspend state.</p> <p>In Host Mode: Read/Write.</p> <p>Port Enabled Bit and Suspend bit of this register define the port states as follows:</p> <p>Bits [Port Enabled, Suspend] Port State</p> <p>0x Disable</p> <p>10 Enable</p> <p>11 Suspend</p> <p>When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction if a transaction was in progress when this bit was written to 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the USB.</p> <p>The host controller will unconditionally set this bit to zero when software sets the <i>Force Port Resume</i> bit to zero. The host controller ignores a write of zero to this bit.</p> <p>If host software sets this bit to a one when the port is not enabled (that is, <i>Port enabled</i> bit is a zero) the results are undefined.</p> <p>This field is zero if <i>Port Power</i>(<a href="#">Port Status &amp; Control (USB_nPORTSC1)</a>) is zero in host mode.</p> <p>In Device Mode: Read Only.</p> <p>In device mode this bit is a read only status bit.</p>
<p>6 FPR</p>	<p>Force Port Resume -Read/Write. 1= Resume detected/driven on port. 0=No resume (K-state) detected/ driven on port. Default = 0.</p> <p>In Host Mode:</p> <p>Software sets this bit to one to drive resume signaling. The Host Controller sets this bit to one if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the <i>Port Change Detect</i> bit in the USBSTS register is also set to one. <i>This bit will automatically change to zero after the resume sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the resume duration is timed in the driver.</i></p> <p>Note that when the Host controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. This bit will remain a one until the port has switched to the high-speed idle. Writing a zero has no effect because the port controller will time the resume operation, clear the bit the port control state switches to HS or FS idle.</p> <p>This field is zero if <i>Port Power</i>(<a href="#">Port Status &amp; Control (USB_nPORTSC1)</a>) is zero in host mode.</p> <p>This bit is not-EHCI compatible.</p> <p>In Device mode:</p>

Table continues on the next page...

## USB\_nPORTSC1 field descriptions (continued)

Field	Description
	After the device has been in Suspend State for 5ms or more, software must set this bit to one to drive resume signaling before clearing. The Device Controller will set this bit to one if a J-to-K transition is detected while the port is in the Suspend state. The bit will be cleared when the device returns to normal operation. Also, when this bit will be cleared because a K-to-J transition detected, the <i>Port Change Detect</i> bit in the USBSTS register is also set to one.
5 OCC	Over-current Change-R/WC. Default=0. This bit is set '1b' by hardware when there is a change to Over-current Active. Software can clear this bit by writing a one to this bit position.
4 OCA	Over-current Active-Read Only. Default 0. This bit will automatically transition from one to zero when the over current condition is removed.  1 This port currently has an over-current condition 0 This port does not have an over-current condition.
3 PEC	Port Enable/Disable Change-R/WC. 1=Port enabled/disabled status has changed. 0=No change. Default = 0. In Host Mode: For the root hub, this bit is set to a one only when a port is disabled due to disconnect on the port or due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification). Software clears this by writing a one to it. This field is zero if <i>Port Power</i> ( <a href="#">Port Status &amp; Control (USB_nPORTSC1)</a> ) is zero. In Device mode: The device port is always enabled, so this bit is always '0b'.
2 PE	Port Enabled/Disabled-Read/Write. 1=Enable. 0=Disable. Default 0. In Host Mode: Ports can only be enabled by the host controller as a part of the reset and enable. Software cannot enable a port by writing a one to this field. Ports can be disabled by either a fault condition (disconnect event or other fault condition) or by the host software. Note that the bit status does not change until the port state actually changes. There may be a delay in disabling or enabling a port due to other host controller and bus events. When the port is disabled, (0b) downstream propagation of data is blocked except for reset. This field is zero if <i>Port Power</i> ( <a href="#">Port Status &amp; Control (USB_nPORTSC1)</a> ) is zero in host mode. In Device Mode: The device port is always enabled, so this bit is always '1b'.
1 CSC	Connect Status Change-R/WC. 1 =Change in Current Connect Status. 0=No change. Default 0. In Host Mode: Indicates a change has occurred in the port's Current Connect Status. The host/device controller sets this bit for all changes to the port device connect status, even if system software has not cleared an existing connect status change. For example, the insertion status changes twice before system software has cleared the changed condition, hub hardware will be 'setting' an already-set bit (that is, the bit will remain set). Software clears this bit by writing a one to it. This field is zero if <i>Port Power</i> ( <a href="#">Port Status &amp; Control (USB_nPORTSC1)</a> ) is zero in host mode. In Device Mode: This bit is undefined in device controller mode.

Table continues on the next page...

## USB\_nPORTSC1 field descriptions (continued)

Field	Description
0 CCS	<p>Current Connect Status-Read Only.</p> <p>In Host Mode:</p> <p>1=Device is present on port. 0=No device is present. Default = 0. This value reflects the current state of the port, and may not correspond directly to the event that caused the <i>Connect Status Change</i> bit (Bit 1) to be set.</p> <p>This field is zero if <i>Port Power</i>(<a href="#">Port Status &amp; Control (USB_nPORTSC1)</a>) is zero in host mode.</p> <p>In Device Mode:</p> <p>1=Attached. 0=Not Attached. Default=0. A one indicates that the device successfully attached and is operating in either high speed or full speed as indicated by the High Speed Port bit in this register. A zero indicates that the device did not attach successfully or was forcibly disconnected by the software writing a zero to the Run bit in the USB_CMD register. It does not state the device being disconnected or suspended.</p>

### 41.7.32 On-The-Go Status & control (USB\_nOTGSC)

This register is available only in OTG controller core. It has four sections:

- OTG Interrupt enables (Read/Write)
- OTG Interrupt status (Read/Write to Clear)
- OTG Status inputs (Read Only)
- OTG Controls (Read/Write)

The status inputs are debounced using a 1 ms time constant. Values on the status inputs that do not persist for more than 1 ms does not cause an update of the status input register, or cause an OTG interrupt.

See also [USB Device Mode \(USB\\_nUSBMODE\)](#) register.

24 IDIE	USB ID Interrupt Enable - Read/Write. Setting this bit enables the USB ID interrupt.
23 -	This field is reserved. Reserved
22 DPIS	Data Pulse Interrupt Status - Read/Write to Clear. This bit is set when data bus pulsing occurs on DP or DM. Data bus pulsing is only detected when USBMODE.CM = Host (11) and PORTSC1(0)[PP] = 0. Software must write a one to clear this bit.
21 STATUS_1MS	1 millisecond timer Interrupt Status - Read/Write to Clear. This bit is set once every millisecond. Software must write a one to clear this bit.
20 BSEIS	B Session End Interrupt Status - Read/Write to Clear. This bit is set when VBus has fallen below the B session end threshold. Software must write a one to clear this bit.
19 BSVIS	B Session Valid Interrupt Status - Read/Write to Clear. This bit is set when VBus has either risen above or fallen below the B session valid threshold. Software must write a one to clear this bit.
18 ASVIS	A Session Valid Interrupt Status - Read/Write to Clear. This bit is set when VBus has either risen above or fallen below the A session valid threshold. Software must write a one to clear this bit.
17 AVVIS	A VBus Valid Interrupt Status - Read/Write to Clear. This bit is set when VBus has either risen above or fallen below the VBus valid threshold on an A device. Software must write a one to clear this bit.
16 IDIS	USB ID Interrupt Status - Read/Write. This bit is set when a change on the ID input has been detected. Software must write a one to clear this bit.

*Table continues on the next page...*

## USB\_nOTGSC field descriptions (continued)

Field	Description
15 -	This field is reserved. Reserved
14 DPS	Data Bus Pulsing Status - Read Only. A '1' indicates data bus pulsing is being detected on the port.
13 TOG_1MS	1 millisecond timer toggle - Read Only. This bit toggles once per millisecond.
12 BSE	B Session End - Read Only. Indicates VBus is below the B session end threshold.
11 BSV	B Session Valid - Read Only. Indicates VBus is above the B session valid threshold.
10 ASV	A Session Valid - Read Only. Indicates VBus is above the A session valid threshold.
9 AVV	A VBus Valid - Read Only. Indicates VBus is above the A VBus valid threshold.
8 ID	USB ID - Read Only. 0 = A device, 1 = B device
7-6 -	This field is reserved. Reserved
5 IDPU	ID Pullup - Read/Write This bit provide control over the ID pull-up resistor; 0 = off, 1 = on [default]. When this bit is 0, the ID input will not be sampled.
4 DP	Data Pulsing - Read/Write. Setting this bit causes the pullup on DP to be asserted for data pulsing during SRP.
3 OT	OTG Termination - Read/Write. This bit must be set when the OTG device is in device mode, this controls the pulldown on DM.
2 -	This field is reserved. Reserved
1 VC	VBUS Charge - Read/Write. Setting this bit causes the VBus line to be charged. This is used for VBus pulsing during SRP.
0 VD	VBUS_Discharge - Read/Write. Setting this bit causes VBus to discharge through a resistor.

### 41.7.33 USB Device Mode (USB\_nUSBMODE)

Address: 402E\_0000h base + 1A8h offset + (512d × i), where i=0d to 1d

USB\_nUSBMODE field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
15 -	This field is reserved. Reserved
14–5 -	This field is reserved. Reserved
4 SDIS	Stream Disable Mode. (0 - Inactive [default]; 1 - Active)  Device Mode: Setting to a '1' disables double priming on both RX and TX for low bandwidth systems. This mode ensures that when the RX and TX buffers are sufficient to contain an entire packet that the standard double buffering scheme is disabled to prevent overruns/underruns in bandwidth limited systems. Note: In High Speed Mode, all packets received are responded to with a NYET handshake when stream disable is active.  Host Mode: Setting to a '1' ensures that overruns/underruns of the latency FIFO are eliminated for low bandwidth systems where the RX and TX buffers are sufficient to contain the entire packet. Enabling stream disable also has the effect of ensuring the TX latency is filled to capacity before the packet is launched onto the USB.  <b>NOTE:</b> Time duration to pre-fill the FIFO becomes significant when stream disable is active. See <a href="#">TX FIFO Fill Tuning (USB_nTXFILLTUNING)</a> and <a href="#">TXTTFILLTUNING [MPH Only]</a> to characterize the adjustments needed for the scheduler when using this feature.

Table continues on the next page...

## USB\_nUSBMODE field descriptions (continued)

Field	Description
	<b>NOTE:</b> The use of this feature substantially limits of the overall USB performance that can be achieved.
3 SLOM	Setup Lockout Mode. In device mode, this bit controls behavior of the setup lock mechanism. See <a href="#">Control Endpoint Operation Model</a> .  0 Setup Lockouts On (default); 1 Setup Lockouts Off (DCD requires use of Setup Data Buffer Tripwire in <a href="#">USB Command Register (USB_nUSBCMD)</a> .
2 ES	Endian Select - Read/Write. This bit can change the byte alignment of the transfer buffers to match the host microprocessor. The bit fields in the microprocessor interface and the data structures are unaffected by the value of this bit because they are based upon the 32-bit word.  Bit Meaning  0 Little Endian [Default] 1 Big Endian
CM	Controller Mode - R/WO. Controller mode is defaulted to the proper mode for host only and device only implementations. For those designs that contain both host & device capability, the controller defaults to an idle state and needs to be initialized to the desired operating mode after reset. For combination host/device controllers, this register can only be written once after reset. If it is necessary to switch modes, software must reset the controller by writing to the <i>RESET</i> bit in the USBCMD register before reprogramming this register.  For OTG controller core, reset value is '00b'.  00 Idle [Default for combination host/device] 01 Reserved 10 Device Controller [Default for device only controller] 11 Host Controller [Default for host only controller]

## 41.7.34 Endpoint Setup Status (USB\_nENDPTSETUPSTAT)

Address: 402E\_0000h base + 1ACh offset + (512d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## USB\_nENDPTSETUPSTAT field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
ENDPTSETUPSTAT	Setup Endpoint Status. For every setup transaction that is received, a corresponding bit in this register is set to one. Software must clear or acknowledge the setup transfer by writing a one to a respective bit after it has read the setup data from Queue head. The response to a setup packet as in the order of operations and total response time is crucial to limit bus time outs while the setup lock our mechanism is engaged. See <a href="#">Managing Endpoints</a> in the Device Operational Model.  This register is only used in device mode.

### 41.7.35 Endpoint Prime (USB\_nENDPTPRIME)

This register is only used in device mode.

When software sets the prime bit for a given endpoint, the device controller loads the transfer descriptor, pointed to by the queue head, such that the endpoint is ready to transmit or receive when the host sends a request (IN/OUT token). The endpoint will NAK all requests from the host until the endpoint is primed. The controller will automatically re-prime the endpoint with a new transfer descriptor when one is found via the next\_dtd pointer of the current transfer descriptor. Hence, the prime bit must only be set by software when a descriptor is added to the queue head.

Address: 402E\_0000h base + 1B0h offset + (512d × i), where i=0d to 1d

#### USB\_nENDPTPRIME field descriptions

Field	Description
31–24 -	This field is reserved. Reserved
23–16 PETB	Prime Endpoint Transmit Buffer - R/WS. For each endpoint a corresponding bit is used to request that a buffer is prepared for a transmit operation in order to respond to a USB IN/INTERRUPT transaction. Software should write a one to the corresponding bit when posting a new transfer descriptor to an endpoint queue head. Hardware automatically uses this bit to begin parsing for a new transfer descriptor from the queue head and prepare a transmit buffer. Hardware clears this bit when the associated endpoint(s) is (are) successfully primed.  <b>NOTE:</b> These bits are momentarily set by hardware during hardware re-priming operations when a dTD is retired, and the dQH is updated.  PETB[N] - Endpoint #N, N is in 0..7
15–8 -	This field is reserved. Reserved
PERB	Prime Endpoint Receive Buffer - R/WS. For each endpoint, a corresponding bit is used to request a buffer prepare for a receive operation for when a USB host initiates a USB OUT transaction. Software should write a one to the corresponding bit whenever posting a new transfer descriptor to an endpoint queue head. Hardware automatically uses this bit to begin parsing for a new transfer descriptor from the queue head and prepare a receive buffer. Hardware clears this bit when the associated endpoint(s) is (are) successfully primed.  <b>NOTE:</b> These bits are momentarily set by hardware during hardware re-priming operations when a dTD is retired, and the dQH is updated.  PERB[N] - Endpoint #N, N is in 0..7

### 41.7.36 Endpoint Flush (USB\_nENDPTFLUSH)

This register is only used in device mode.

Address: 402E\_0000h base + 1B4h offset + (512d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## USB\_nENDPTCTRL0 field descriptions

Field	Description
31–24 -	This field is reserved. Reserved
23 TXE	TX Endpoint Enable 1 Enabled

Table continues on the next page...

**USB\_nENDPTCTRL0 field descriptions (continued)**

Field	Description
	Endpoint0 is always enabled.
22–20 -	This field is reserved. Reserved
19–18 TXT	TX Endpoint Type - Read/Write 00 - Control Endpoint0 is fixed as a Control End Point.
17 -	This field is reserved. Reserved
16 TXS	TX Endpoint Stall - Read/Write 0 End Point OK [Default] 1 End Point Stalled  Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. It continues returning STALL until the bit is cleared by software or it is automatically cleared upon receipt of a new SETUP request.  After receiving a SETUP request, this bit will continue to be cleared by hardware until the associated ENDPTSETUPSTAT bit is cleared.  <b>NOTE:</b> There is a slight delay (50 clocks max.) between the endptsetupstat being cleared and hardware continuing to clear this bit. In most systems it is unlikely the DCD software will observe this delay. However, should the dcd observe that the stall bit is not set after writing a one to it then follow this procedure: continually write this stall bit until it is set or until a newsetup has been received by checking the associated endptsetupstat bit.
15–8 -	This field is reserved. Reserved
7 RXE	RX Endpoint Enable 1 Enabled Endpoint0 is always enabled.
6–4 -	This field is reserved. Reserved
3–2 RXT	RX Endpoint Type - Read/Write 00 Control Endpoint0 is fixed as a Control End Point.
1 -	This field is reserved. Reserved
0 RXS	RX Endpoint Stall - Read/Write 0 End Point OK. [Default] 1 End Point Stalled  Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. It continues returning STALL until the bit is cleared by software or it is automatically cleared upon receipt of a new SETUP request.  After receiving a SETUP request, this bit will continue to be cleared by hardware until the associated ENDPTSETUPSTAT bit is cleared.

*Table continues on the next page...*

## USB\_nENDPTCTRL0 field descriptions (continued)

Field	Description
	<b>NOTE:</b> There is a slight delay (50 clocks max.) between the endptsetupstat being cleared and hardware continuing to clear this bit. In most systems it is unlikely the dcd software will observe this delay. However, should the dcd observe that the stall bit is not set after writing a one to it then follow this procedure: continually write this stall bit until it is set or until a newsetup has been received by checking the associated endptsetupstat bit.

## 41.7.40 Endpoint Control 1 (USB\_nENDPTCTRL1)

This is endpoint control register for endpoint 1 in device operation mode.

**NOTE**

If one endpoint direction is enabled and the paired endpoint of opposite direction is disabled then the unused direction type must be changed from the default control-type to any other type (that is Bulk-type). leaving an unconfigured endpoint control causes undefined behavior for the data pid tracking on the active endpoint/direction.

Address: 402E\_0000h base + 1C4h offset + (512d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved								TXE	TXR	TXI	Reserved	TXT	TXD	TXS

1 RXD	RX Endpoint Data Sink - Read/Write 0 Dual Port Memory Buffer/DMA Engine [Default] Should always be written as zero.
0 RXS	RX Endpoint Stall - Read/Write 0 End Point OK. [Default] 1 End Point Stalled  This bit is set automatically upon receipt of a SETUP request if this Endpoint is configured as a Control Endpoint and this bit will continue to be cleared by hardware until the associated ENDPTSETUPSTAT bit is cleared.  Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. This control will continue to STALL until this bit is either cleared by software or automatically cleared as above for control endpoints.  <b>NOTE:</b> [CONTROL ENDPOINT TYPES ONLY]: there is a slight delay (50 clocks max) between the ENDPTSETUPSTAT begin cleared and hardware continuing to clear this bit. In most systems, it is unlikely the DCD software will observe this delay. However, should the DCD observe that the stall bit is not set after writing a one to it then follow this procedure: continually write this stall bit until it is set or until a new setup has been received by checking the associated endptsetupstat bit.

### 41.7.42 Endpoint Control 3 (USB\_nENDPTCTRL3)

This is endpoint control register for endpoint 3 in device operation mode.

#### NOTE

If one endpoint direction is enabled and the paired endpoint of opposite direction is disabled then the unused direction type must be changed from the default control-type to any other type (that is Bulk-type). leaving an unconfigured endpoint control

causes undefined behavior for the data pid tracking on the active endpoint/direction.

Address: 402E\_0000h base + 1CCh offset + (512d × i), where i=0d to 1d

**USB\_nENDPTCTRL3 field descriptions**

Field	Description
31–24 -	This field is reserved. Reserved
23 TXE	TX Endpoint Enable 0 Disabled [Default] 1 Enabled An Endpoint should be enabled only after it has been configured.
22 TXR	TX Data Toggle Reset (WS) Write 1 - Reset PID Sequence Whenever a configuration event is received for this Endpoint, software must write a one to this bit in order to synchronize the data PID's between the Host and device.
21 TXI	TX Data Toggle Inhibit 0 PID Sequencing Enabled. [Default] 1 PID Sequencing Disabled. This bit is only used for test and should always be written as zero. Writing a one to this bit causes this endpoint to ignore the data toggle sequence and always transmit DATA0 for a data packet.
20 -	This field is reserved. Reserved

Table continues on the next page...

**USB\_nENDPTCTRL3 field descriptions (continued)**

Field	Description
19–18 TXT	TX Endpoint Type - Read/Write 00 Control 01 Isochronous 10 Bulk 11 Interrupt
17 TXD	TX Endpoint Data Source - Read/Write 0 Dual Port Memory Buffer/DMA Engine [DEFAULT] Should always be written as 0.
16 TXS	TX Endpoint Stall - Read/Write 0 End Point OK 1 End Point Stalled  This bit will be cleared automatically upon receipt of a SETUP request if this Endpoint is configured as a Control Endpoint and this bit will continue to be cleared by hardware until the associated ENDPTSETUPSTAT bit is cleared.  Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. This control will continue to STALL until this bit is either cleared by software or automatically cleared as above for control endpoints.  <b>NOTE:</b> [CONTROL ENDPOINT TYPES ONLY]: there is a slight delay (50 clocks max) between the ENDPTSETUPSTAT begin cleared and hardware continuing to clear this bit. In most systems, it is unlikely the DCD software will observe this delay. However, should the DCD observe that the stall bit is not set after writing a one to it then follow this procedure: continually write this stall bit until it is set or until a new setup has been received by checking the associated endptsetupstat bit.
15–8 -	This field is reserved. Reserved
7 RXE	RX Endpoint Enable 0 Disabled [Default] 1 Enabled  An Endpoint should be enabled only after it has been configured.
6 RXR	RX Data Toggle Reset (WS) Write 1 - Reset PID Sequence  Whenever a configuration event is received for this Endpoint, software must write a one to this bit in order to synchronize the data PID's between the host and device.
5 RXI	RX Data Toggle Inhibit 0 Disabled [Default] 1 Enabled  This bit is only used for test and should always be written as zero. Writing a one to this bit causes this endpoint to ignore the data toggle sequence and always accept data packet regardless of their data PID.
4 -	This field is reserved. Reserved.
3–2 RXT	RX Endpoint Type - Read/Write 00 Control

*Table continues on the next page...*

Field	Description
	01 Isochronous 10 Bulk 11 Interrupt
1 RXD	RX Endpoint Data Sink - Read/Write 0 Dual Port Memory Buffer/DMA Engine [Default] Should always be written as zero.
0 RXS	RX Endpoint Stall - Read/Write 0 End Point OK. [Default] 1 End Point Stalled  This bit is set automatically upon receipt of a SETUP request if this Endpoint is configured as a Control Endpoint and this bit will continue to be cleared by hardware until the associated ENDPTSETUPSTAT bit is cleared.  Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. This control will continue to STALL until this bit is either cleared by software or automatically cleared as above for control endpoints.  <b>NOTE:</b> [CONTROL ENDPOINT TYPES ONLY]: there is a slight delay (50 clocks max) between the ENDPTSETUPSTAT begin cleared and hardware continuing to clear this bit. In most systems, it is unlikely the DCD software will observe this delay. However, should the DCD observe that the stall bit is not set after writing a one to it then follow this procedure: continually write this stall bit until it is set or until a new setup has been received by checking the associated endptsetupstat bit.

**41.7.43 Endpoint Control 4 (USB\_nENDPTCTRL4)**

This is endpoint control register for endpoint 4 in device operation mode.

**NOTE**

If one endpoint direction is enabled and the paired endpoint of opposite direction is disabled then the unused direction type must be changed from the default control-type to any other type (that is Bulk-type). leaving an unconfigured endpoint control causes undefined behavior for the data pid tracking on the active endpoint/direction.

Interrupts, DMA Events and XBAR Assignments	-	<a href="#">Interrupts, DMA Events and XBAR Assignments</a>

### 42.2 USB PHY Overview

The chip contains 2 integrated USB 2.0 PHY macrocells capable of connecting to USB host/device systems at the USB low-speed (LS) rate of 1.5 Mbits/s, full-speed (FS) rate of 12 Mbits/s or at the USB 2.0 high-speed (HS) rate of 480 Mbits/s.

The integrated PHY provides a standard UTM interface. The USB<sub>n</sub>\_DN and USB<sub>n</sub>\_DP pins connect directly to a USB connector.

The following subsections describe the external interfaces, internal interfaces, major blocks, and programmable registers that comprise the integrated USB 2.0 PHY.

## 42.3 Operation

The UTM provides a 16-bit interface to the USB controller. This interface is clocked at 30 MHz.

- The digital portions of the USBPHY block include the UTMI, digital transmitter, digital receiver, and the programmable registers.
- The analog transceiver section comprises an analog receiver and an analog transmitter, as shown in [Figure 42-1](#).

### 42.3.1 UTMI

The UTMI block handles the line\_state bits, reset buffering, suspend distribution, transceiver speed selection, and transceiver termination selection.

The PLL supplies a 120 MHz signal to all of the digital logic. The UTMI block does a final divide-by-four to develop the 30 MHz clock used in the interface.

### 42.3.2 Digital Transmitter

The digital transmitter receives the 16-bit transmit data from the USB controller and handles the tx\_valid, tx\_validh and tx\_ready handshake.

In addition, it contains the transmit serializer that converts the 16-bit parallel words at 30 MHz to a single bitstream at 480 Mbit for high-speed or 12 Mbit for full-speed or 1.5 Mbit for low-speed. It does this while implementing the bit-stuffing algorithm and the NRZI encoder that are used to remove the DC component from the serial bitstream. The output of this encoder is sent to the low-speed (LS), full-speed (FS) or high-speed (HS) drivers in the analog transceiver section's transmitter block.

### 42.3.3 Digital Receiver

The digital receiver receives the raw serial bitstream from the low speed (LS) differential transceiver, full speed (FS) differential transceiver, and a 9X, 480 MHz sampled data from the high speed (HS) differential transceiver.

As the phase of the USB host transmitter shifts relative to the local PLL, the receiver section's HS DLL tracks these changes to give a reliable sample of the incoming 480 Mbit/s bitstream. Since this sample point shifts relative to the PLL phase used by the digital logic, a rate-matching elastic buffer is provided to cross this clock domain

boundary. Once the bitstream is in the local clock domain, an NRZI decoder and bit unstuffing restore the original payload data bitstream and pass it to a deserializer and holding register. The receive state machine handles the rx\_valid, rx\_validh, and handshake with the USB controller. The handshake is not interlocked, in that there is no rx\_ready signal coming from the controller. The controller must take each 16-bit value as presented by the PHY. The receive state machine provides an rx\_active signal to the controller that indicates when it is inside a valid packet (SYNC detected, and so on).

### 42.3.4 Analog Receiver

The analog receiver comprises five differential receivers, two single-ended receivers, and a 9X, 480 MHz HS data sampling module

, as shown in the figure below and described further in this section.

**Figure 42-1. USB 2.0 PHY Analog Transceiver Block Diagram**

#### 42.3.4.1 HS Differential Receiver

The high-speed differential receiver is both a differential analog receiver and threshold comparator. Its output is a one if the differential signal is greater than a 0-V threshold.

Otherwise, its output is 0. Its purpose is to discriminate the  $\pm 400$ -mV differential voltage resulting from the high-speed drivers current flow into the dual  $45\Omega$  terminations found on each pin of the differential pair. The envelope or squelch detector, described below, ensures that the differential signal has sufficient magnitude to be valid. The HS differential receiver tolerates up to 500 mV of common mode offset.

#### 42.3.4.2 Squelch Detector

The squelch detector is a differential analog receiver and threshold comparator.

Its output is 1, if the differential magnitude is less than a nominal 100 mV threshold. Otherwise, its output is 0.

Its purpose is to invalidate the HS differential receiver when the incoming signal is simply too low to receive reliably.

#### 42.3.4.3 LS/FS Differential Receiver

The low-speed/full-speed differential receiver is both a differential analog receiver and threshold comparator.

The crossover voltage falls between 1.3 V and 2.0 V. Its output is 1, when the USB<sub>n</sub>\_DP line is above the crossover point and the USB<sub>n</sub>\_DN line is below the crossover point. The digital receiver section decodes the receiver data into J or K state according to the speed.

#### 42.3.4.4 HS Disconnect Detector

It is a differential analog receiver and threshold comparator. It outputs high when differential magnitude is greater than a nominal 575-mV threshold. Otherwise, it outputs low.

#### 42.3.4.5 USB Plugged-In Detector

The USB plugged-in detector looks for both USB<sub>n</sub>\_DP and USB<sub>n</sub>\_DN to be high. There is a pair of large on-chip pullup resistors (200 K $\Omega$ ) that hold both USB<sub>n</sub>\_DP and USB<sub>n</sub>\_DN high when the USB cable is not attached. The USB plugged-in detector signals a 0 in this case.

When operating in device mode, the upstream port in host/hub interface contains a 15 K $\Omega$  pulldown resistor which could easily override the 200 K $\Omega$  pullup resistor. When plugged in, at least one signal in the pair will be low, which will force the plugged-in detector's output high.

#### **42.3.4.6 Single-Ended USB\_DP Receiver**

The single-ended USB\_n\_DP receiver output is high whenever the USB\_n\_DP input is above its nominal 1.8 V threshold.

#### **42.3.4.7 Single-Ended USB\_DN Receiver**

The single-ended USB\_n\_DN receiver output is high whenever the USB\_n\_DN input is above its nominal 1.8 V threshold.

#### **42.3.4.8 9X Oversample Module**

The 9X oversample module uses nine identically spaced phases of the 480 MHz clock to sample a high speed bit data. The squelch signal is sampled only 1X.

### **42.3.5 Analog Transmitter**

The analog transmitter comprises two differential drivers: one for high-speed signaling and one for full-speed signaling. It also contains the switchable 1.5 K $\Omega$  pullup resistor.

See [Figure 42-1](#).

#### **42.3.5.1 Switchable High-Speed 45 $\Omega$ Termination Resistors**

High-speed current mode differential signaling requires good 90  $\Omega$  differential termination at each end of the USB cable. This results from switching in 45  $\Omega$  terminating resistors from each signal line to ground at each end of the cable.

Because each signal is parallel terminated with 45  $\Omega$  at each end, each driver sees a 22.5  $\Omega$  load. This load impedance is much too low for full-speed signaling levels—hence the need for switchable high-speed terminating resistors. Switchable trimming resistors are provided to tune the actual termination resistance of each device, as shown in [Figure](#)

42-2. The HW\_USBPHY\_TX\_TXCAL45DP bit field, for example, allows one of 16 trimming resistor values to be placed in parallel with the 45 $\Omega$  terminator on the USB<sub>n</sub>\_DP signal.

### 42.3.5.2 Low-Speed/Full-Speed Differential Driver

The low-speed/full-speed differential drivers are essentially low-impedance pulldown devices that are switched in a differential mode for low-speed or full-speed signaling, that is, either one or the other device is turned on to signal the "J" state or the "K" state.

### 42.3.5.3 High-Speed Differential Driver

The high-speed differential driver receives a 17.78 mA current from the constant current source ( $I_{ref}$ ) and essentially steers it down either the USB\_DP signal or the USB\_DN signal or alternatively to ground.

This current will produce approximately a 400 mV drop across the 22.5  $\Omega$  termination seen by the driver when it is steered onto one of the signal lines. The approximately 17.78 mA current source is referenced back to the integrated voltage-band-gap ( $V_{bg}$ ) circuit. The  $I_{ref}$ ,  $I_{bias}$ , and  $V$  to  $I$  circuits are shared with the integrated battery charger.

### 42.3.5.4 Switchable 1.5K $\Omega$ USB\_DP Pullup Resistor

This product contains a switchable 1.5 K $\Omega$  pullup resistor on the USB<sub>n</sub>\_DP signal.

This resistor is switched on to indicate to the host/hub controller that a full-speed-capable device is on the USB cable, powered on, and ready. This resistor is switched off at power-on reset so the host does not recognize a USB device until the processor software enables the announcement of a full-speed device.

### 42.3.5.5 Switchable 15KΩ USB\_DP Pulldown Resistor

This product contains a switchable 15 KΩ pulldown resistor on both USB\_n\_DP and USB\_n\_DN signals. This is used in host mode to indicate to the device controller that a host is present.

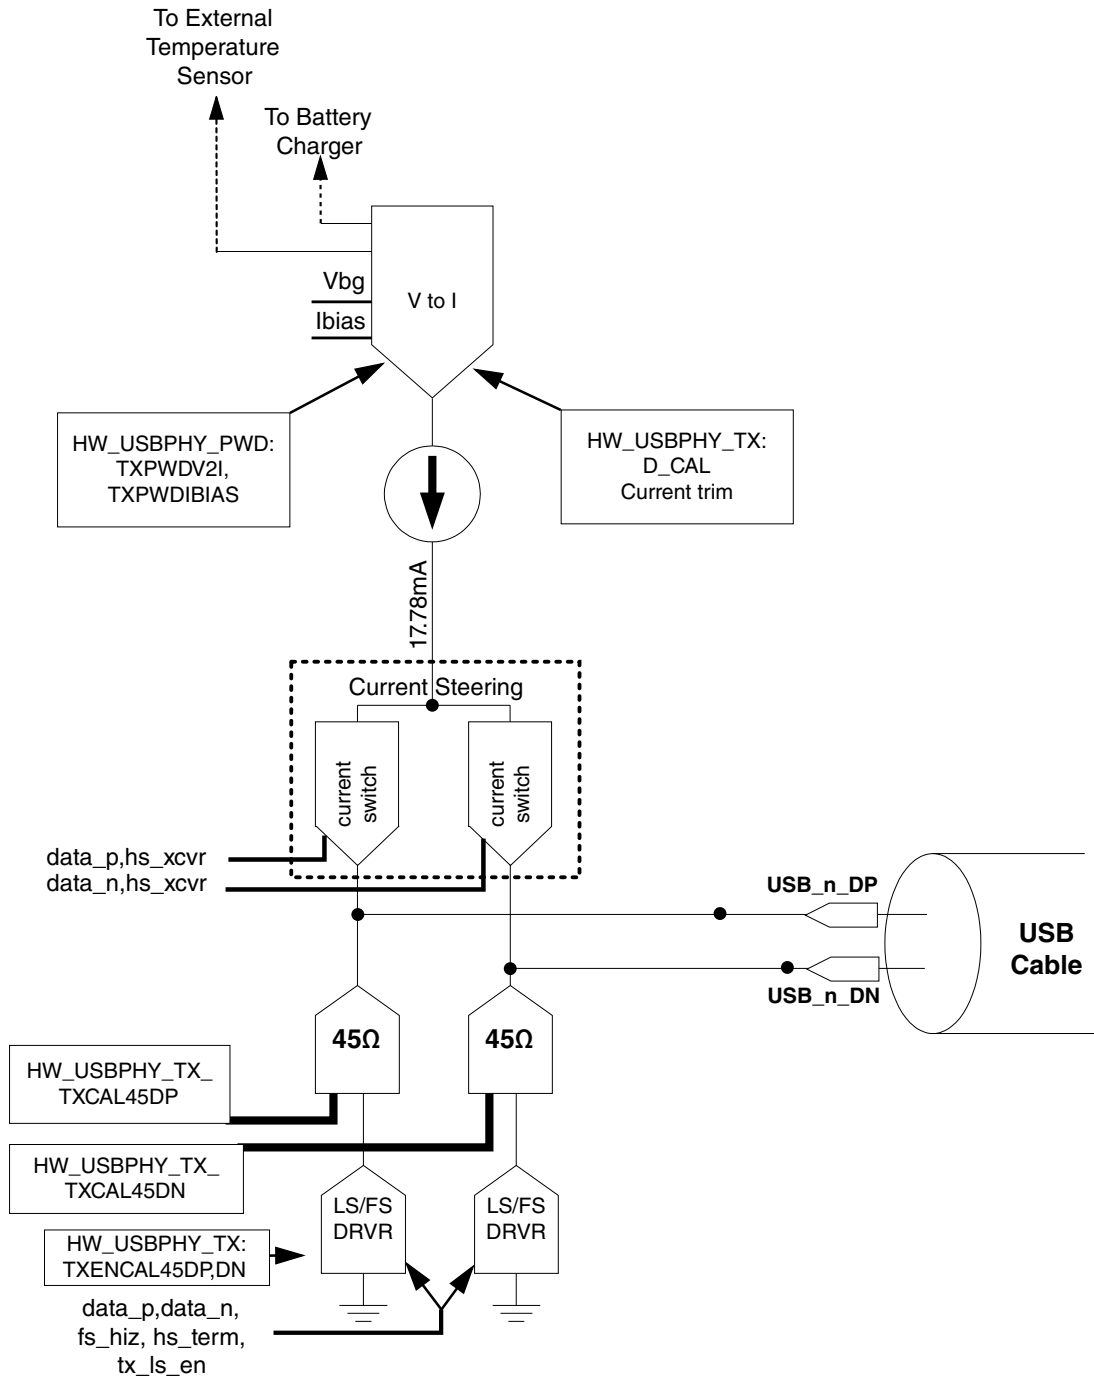

Figure 42-2. USB 2.0 PHY Transmitter Block Diagram

### 42.3.6 Recommended Register Configuration for USB Certification

The register settings in this section are recommended for passing USB certification.

The following settings lower the J/K levels to certifiable limits:

```
HW_USBPHY_TX_TXCAL45DP = 0x0
HW_USBPHY_TX_TXCAL45DN = 0x0
HW_USBPHY_TX_D_CAL = 0x7
```

### 42.3.7 Charger detection

The USB charger detector is a block that detects whether the upstream-facing device is connected to a down-stream facing charger, either a dedicated USB charger or a host charger.

The USB charger detector is comprised of two sub-blocks, namely the USB data-pin contact detector and the charger detector.

This section details those two sub-blocks and gives the software flow of USB charger detection. Finally, this chapter discusses the detection of a USB charger in case of a dead battery.

#### 42.3.7.1 Charger detect control table

Before we dive into the details of the detectors, we show the logic table of the control signals to give the user an overall picture of the charger detector.

**Table 42-2. Charger detection control table**

EN_B	CHK_CHRG_B	CHK_CONTACT	Data pin contact detector	Charger detector
0	1	1	Enabled	Disabled
0	0	x(don't care)	Disabled	Enabled
1	x	x(don't care)	Disabled	Disabled

### 42.3.7.2 Data pin contact detector

According to Battery Charging Specification (rev 1.2), USB plugs and receptacles are designed such that when the plug is inserted into the receptacle, the power pins make contact before the data pins make contact. Therefore, there is inevitably a time interval during which USB<sub>n</sub>\_VBUS has been observed by the device while the USB<sub>n</sub>\_DP and USB<sub>n</sub>\_DN pins are not still pending for contact. The USB data pin contact detector is designed to give the software an indication of the contact of the data pins.

To enable the USB data pin contact detector, the user should set the CHK\_CONTACT bit of the USB1\_CHRG\_DETECT register to 1 and monitor the PLUG\_CONTACT bit status of the USB1\_CHRG\_DETECT\_STAT register. If PLUG\_CONTACT is 1, then it indicates that the data pins have made good contacts, otherwise the user should continue to wait until this bit is set.

According to Table 1, it should be noted that the data pin contact detector only works when EN\_B=0 and CHK\_CHRG\_B=1, both bits being of the USB1\_CHRG\_DETECT register.

### 42.3.7.3 Charger detector

Once the data pins make contact, the user should enable the charger detector by clearing the CHK\_CHRG\_B bit that is low-active. Then the user should wait for 40ms and then check the status bit of CHRГ\_DETECTED in register hw\_anadig\_usb1\_chrg\_det\_stat. CHRГ\_DETECTED=1 means that the device is connected to a charger, either a dedicated charger or a charging downstream port (or equivalently called a host charger, or charging host). To further differentiate between a host charger and a dedicated charger, the user is suggested to pull up USB<sub>n</sub>\_DP signaling a connect event to the host. Then the user should monitor the USB<sub>n</sub>\_DN line status. If USB<sub>n</sub>\_DN=1, then the charger is a dedicated charger; if USB<sub>n</sub>\_DN=0, then it is a host charger.

### 42.3.7.4 Charger detection software flow

Upon seeing VBUS, the software should follow the software flow for the charger detection process. The flow chart mentions the "enable the vdd3p0 current limiter". Please refer to the power chapter for details.

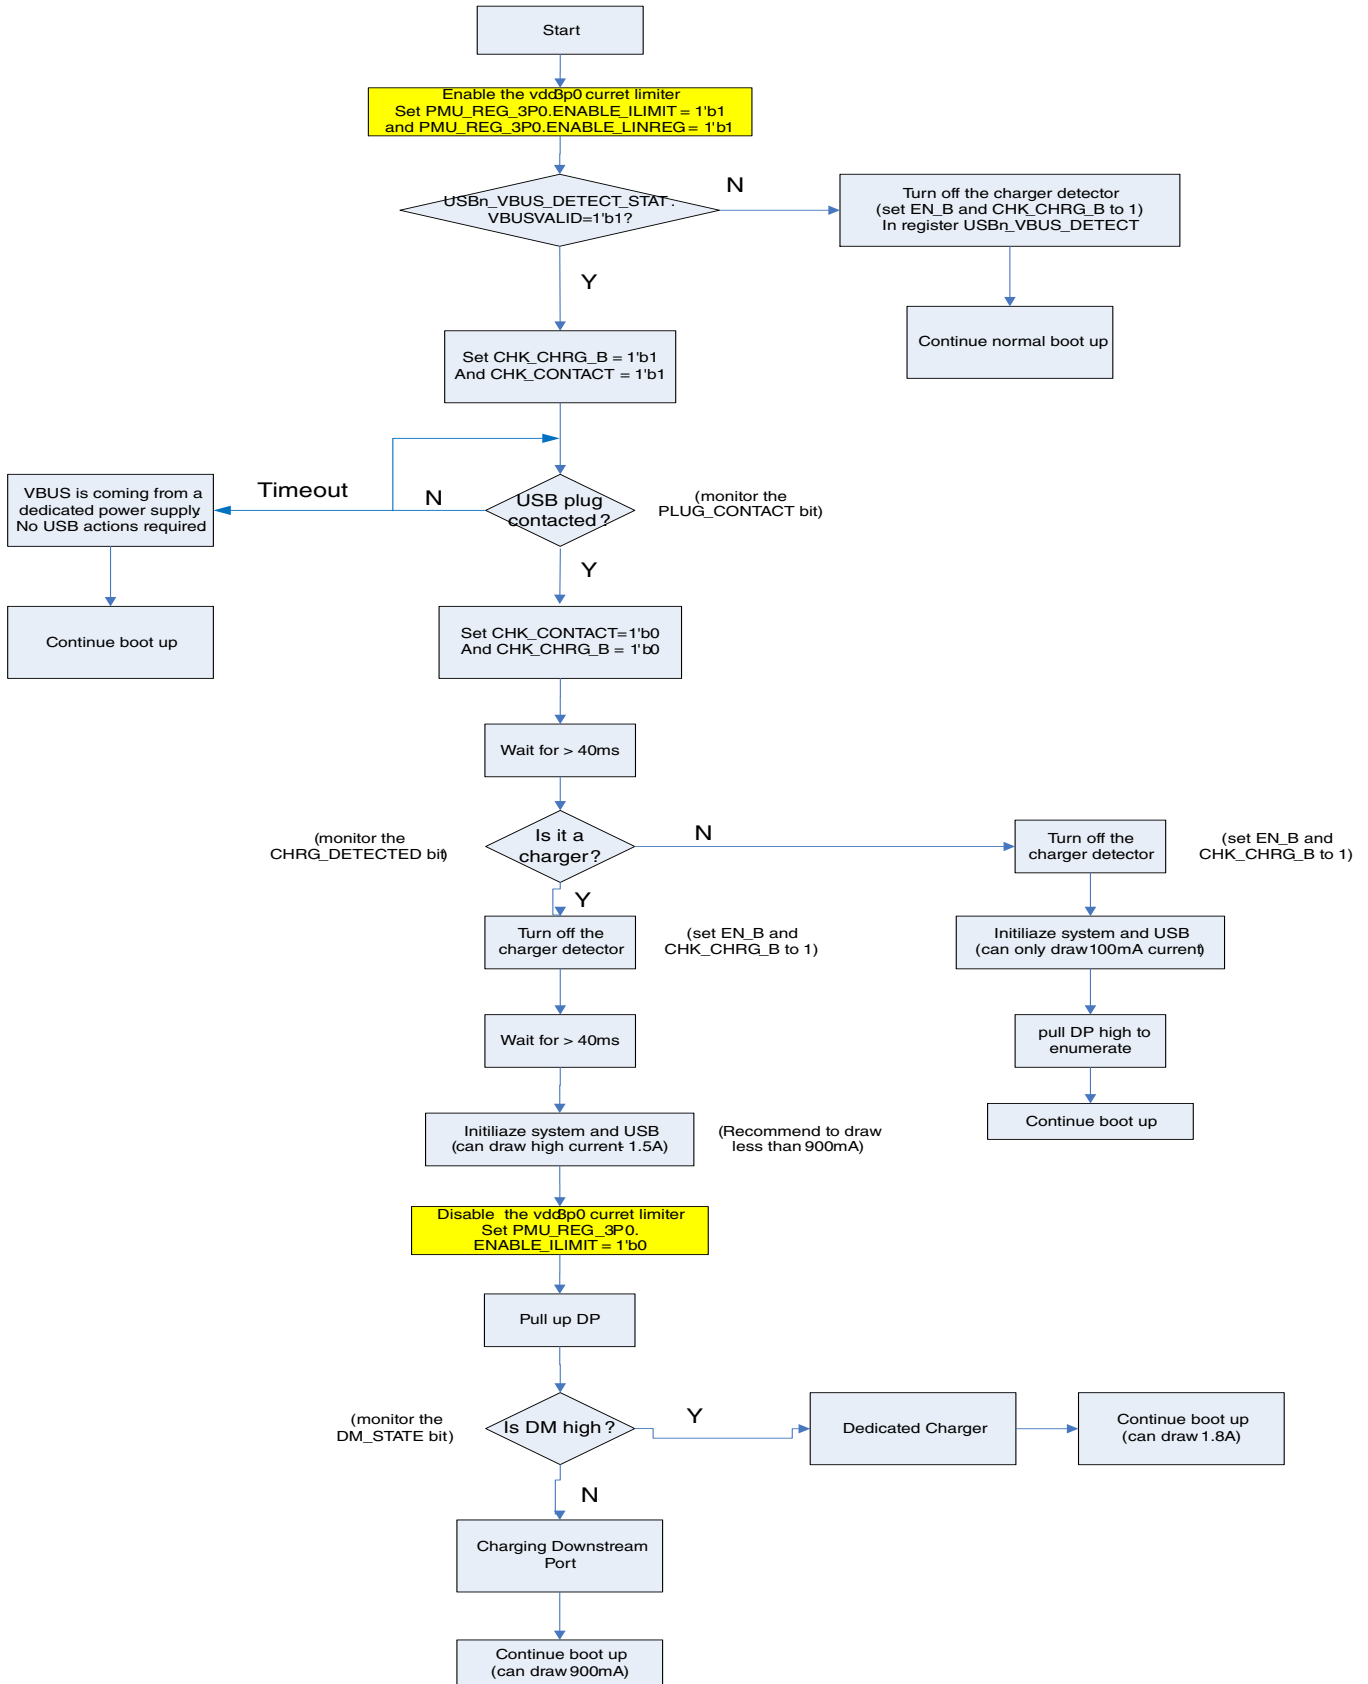

Figure 42-3. USBPHY Charger Detection Software Flow

### 42.3.7.5 Dead Battery Protect

All the descriptions above are based on the assumption that all the power supplies have been on when the device is plugged into a remote host (or charger). However, there are cases when the local battery of the portable device has been so depleted that the system could not be turned on. In such scenarios the user may prefer a method of signaling the external power management unit (PMIC) the existence of the USB charger to draw a current larger than 100mA from the remote host to speed up system boot up or battery charging. The charger detector indeed supports this function.

When we have a fully depleted battery, all the power supplies might be off. Upon insertion of the 5V, the supplies are brought up by the external PMIC and the internal regulators. Due to the 100mA inrush current limit of the USB spec, we cannot draw larger than 100mA current which might be a limit for system boot-up. Since by default, EN\_B=0, CHK\_CHRG\_B=0 and CHK\_CONTACT=1, the usb charger detector is automatically enabled without any software operation needed and it can signal the external PMIC the existence of a USB charger through the open-drain output pin USB\_OTG\_CHD\_B. This pin should be pulled up to an external voltage that is acceptable to the PMIC. If this signal is low, then the PMIC can get that the device is connected to a charger. In this case, the PMIC can draw more than 100mA current from the USB.

It should be noted that this function requires cooperation between the chip and the external PMIC. It is suggested that the user consult NXP for such use cases.

## 42.4 USB PHY Memory Map/Register Definition

### USBPHY Hardware Register Format Summary

#### USBPHY memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
400D_9000	USB PHY Power-Down Register (USBPHY1_PWD)	32	R/W	001E_1C00h	<a href="#">42.4.1/2573</a>
400D_9004	USB PHY Power-Down Register (USBPHY1_PWD_SET)	32	R/W	001E_1C00h	<a href="#">42.4.1/2573</a>
400D_9008	USB PHY Power-Down Register (USBPHY1_PWD_CLR)	32	R/W	001E_1C00h	<a href="#">42.4.1/2573</a>

### 42.4.1 USB PHY Power-Down Register (USBPHYx\_PWDn)

The USB PHY Power-Down Register provides overall control of the PHY power state. Before programming this register, the PHY clocks must be enabled in registers USBPHYx\_CTRLn and CCM\_ANALOG\_USBPHYx\_PLL\_480\_CTRLn.

Address: Base address + 0h offset + (4d × i), where i=0d to 3d

**USBPHYx\_PWDn field descriptions**

Field	Description
31–21 RSVD2	Reserved.
20 RXPWDRX	0 = Normal operation. 1 = Power-down the entire USB PHY receiver block except for the full-speed differential receiver. Note that this bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHYx_CTRL is enabled.
19 RXPWDDIFF	0 = Normal operation. 1 = Power-down the USB high-speed differential receiver.

*Table continues on the next page...*

**USBPHYx\_PWDn field descriptions (continued)**

Field	Description
	Note that this bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHYx_CTRL is enabled.
18 RXPWD1PT1	0 = Normal operation. 1 = Power-down the USB full-speed differential receiver.  Note that this bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHYx_CTRL is enabled.
17 RXPWDENV	0 = Normal operation. 1 = Power-down the USB high-speed receiver envelope detector (squelch signal).  Note that this bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHYx_CTRL is enabled.
16–13 RSVD1	Reserved.
12 TXPWDV2I	0 = Normal operation. 1 = Power-down the USB PHY transmit V-to-I converter and the current mirror.  Note that this bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHYx_CTRL is enabled.  Note that these circuits are shared with the battery charge circuit. Setting this to 1 does not power-down these circuits, unless the corresponding bit in the battery charger is also set for power-down.
11 TXPWDIBIAS	0 = Normal operation. 1 = Power-down the USB PHY current bias block for the transmitter. This bit should be set only when the USB is in suspend mode. This effectively powers down the entire USB transmit path.  Note that this bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHYx_CTRL is enabled.  Note that these circuits are shared with the battery charge circuit. Setting this bit to 1 does not power-down these circuits, unless the corresponding bit in the battery charger is also set for power-down.
10 TXPWDIFS	0 = Normal operation. 1 = Power-down the USB full-speed drivers. This turns off the current starvation sources and puts the drivers into high-impedance output.  Note that this bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHYx_CTRL is enabled.
RSVD0	Reserved.

## 42.4.2 USB PHY Transmitter Control Register (USBPHYx\_TXn)

The USB PHY Transmitter Control Register handles the transmit controls.

Address: Base address + 10h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	RSVD5			USBPHY_TX_ EDGECTRL			RSVD2				TXCAL45DP					
W																
Reset	0	0	0	1	0	0	0	0	0	0	0	0	0	1	1	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RSVD1				TXCAL45DN				RSVD0				D_CAL			
W																
Reset	0	0	0	0	0	1	1	0	0	0	0	0	0	1	1	1

### USBPHYx\_TXn field descriptions

Field	Description
31–29 RSVD5	Reserved.
28–26 USBPHY_TX_ EDGECTRL	Controls the edge-rate of the current sensing transistors used in HS transmit. NOT FOR CUSTOMER USE.
25–20 RSVD2	Reserved.
19–16 TXCAL45DP	Decode to select a 45-Ohm resistance to the USB_DP output pin. Maximum resistance = 0000. Resistance is centered by design at 0110.
15–12 RSVD1	Reserved. <b>Note:</b> This bit should remain clear.
11–8 TXCAL45DN	Decode to select a 45-Ohm resistance to the USB_DN output pin. Maximum resistance = 0000. Resistance is centered by design at 0110.
7–4 RSVD0	Reserved. <b>Note:</b> This bit should remain clear.
D_CAL	Resistor Trimming Code: 0000 = 0.16% 0111 = Nominal 1111 = +25%

### 42.4.3 USB PHY Receiver Control Register (USBPHYx\_RXn)

The USB PHY Receiver Control Register handles receive path controls.

Address: Base address + 20h offset + (4d × i), where i=0d to 3d

**USBPHYx\_RXn field descriptions**

Field	Description
31–23 RSVD2	Reserved.
22 RXDBYPASS	0 = Normal operation. 1 = Use the output of the USB_DP single-ended receiver in place of the full-speed differential receiver. This test mode is intended for lab use only.
21–7 RSVD1	Reserved.

Table continues on the next page...

**USBPHYx\_RXn field descriptions (continued)**

Field	Description
6-4 DISCONADJ	The DISCONADJ field adjusts the trip point for the disconnect detector: 000 = Trip-Level Voltage is 0.57500 V 001 = Trip-Level Voltage is 0.56875 V 010 = Trip-Level Voltage is 0.58125 V 011 = Trip-Level Voltage is 0.58750 V 1XX = Reserved
3 RSVD0	Reserved.
ENVADJ	The ENVADJ field adjusts the trip point for the envelope detector. 000 = Trip-Level Voltage is 0.12500 V 001 = Trip-Level Voltage is 0.10000 V 010 = Trip-Level Voltage is 0.13750 V 011 = Trip-Level Voltage is 0.15000 V 1XX = Reserved

### 42.4.4 USB PHY General Control Register (USBPHYx\_CTRLn)

The USB PHY General Control Register handles OTG and Host controls. This register also includes interrupt enables and connectivity detect enables and results.

Address: Base address + 30h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R

## USBPHYx\_CTRLn field descriptions

Field	Description
31 SFTRST	Writing a 1 to this bit will soft-reset the USBPHYx_PWD, USBPHYx_TX, USBPHYx_RX, and USBPHYx_CTRL registers. Set to 0 to release the PHY from reset.
30 CLKGATE	Gate UTMI Clocks. Clear to 0 to run clocks. Set to 1 to gate clocks. Set this to save power while the USB is not actively being used. Configuration state is kept while the clock is gated.  Note this bit can be auto-cleared if there is any wakeup event when USB is suspended while ENAUTOCLR_CLKGATE bit of USBPHYx_CTRL is enabled.
29 UTMI_SUSPENDM	Used by the PHY to indicate a powered-down state. If all the power-down bits in the USBPHYx_PWD are enabled, UTMI_SUSPENDM will be 0, otherwise 1. UTMI_SUSPENDM is negative logic, as required by the UTMI specification.
28 HOST_FORCE_LS_SE0	Forces the next FS packet that is transmitted to have a EOP with LS timing. This bit is used in host mode for the resume sequence. After the packet is transferred, this bit is cleared. The design can use this function to force the LS SE0 or use the USBPHYx_CTRL_UTMI_SUSPENDM to trigger this event when leaving suspend. This bit is used in conjunction with USBPHYx_DEBUG_HOST_RESUME_DEBUG.
27 OTG_ID_VALUE	Almost same as OTGID_STATUS in USBPHYx_STATUS Register. The only difference is that OTG_ID_VALUE has debounce logic to filter the glitches on ID Pad.
26–25 RSVD1	Reserved.
24 FSDLL_RST_EN	Enables the feature to reset the FSDLL lock detection logic at the end of each TX packet.
23 ENVBUSCHG_WKUP	Enables the feature to wakeup USB if VBUS is toggled when USB is suspended.
22 ENIDCHG_WKUP	Enables the feature to wakeup USB if ID is toggled when USB is suspended.
21 ENDPDMCHG_WKUP	Enables the feature to wakeup USB if DP/DM is toggled when USB is suspended. This bit is enabled by default.
20 ENAUTOCLR_PHY_PWD	Enables the feature to auto-clear the PWD register bits in USBPHYx_PWD if there is wakeup event while USB is suspended. This should be enabled if needs to support auto wakeup without S/W's interaction.
19 ENAUTOCLR_CLKGATE	Enables the feature to auto-clear the CLKGATE bit if there is wakeup event while USB is suspended. This should be enabled if needs to support auto wakeup without S/W's interaction.
18 ENAUTO_PWRON_PLL	Enables the feature to auto-enable the POWER bit of HW_CLKCTRL_PLLxCTRL0 if there is wakeup event if USB is suspended. This should be enabled if needs to support auto wakeup without S/W's interaction.
17 WAKEUP_IRQ	Indicates that there is a wakeup event. Reset this bit by writing a 1 to the clear address space and not by a general write.
16 ENIRQWAKEUP	Enables interrupt for the wakeup events.
15 ENUTMILEVEL3	Enables UTMI+ Level3. This should be enabled if needs to support external FS Hub with LS device connected
14 ENUTMILEVEL2	Enables UTMI+ Level2. This should be enabled if needs to support LS device
13 DATA_ON_LRADC	Enables the LRADC to monitor USB_DP and USB_DM. This is for use in non-USB modes only.
12 DEVPLUGIN_IRQ	Indicates that the device is connected. Reset this bit by writing a 1 to the clear address space and not by a general write.

Table continues on the next page...

## USBPHYx\_CTRLn field descriptions (continued)

Field	Description
11 ENIRQDEVPLUGIN	Enables interrupt for the detection of connectivity to the USB line.
10 RESUME_IRQ	Indicates that the host is sending a wake-up after suspend. This bit is also set on a reset during suspend. Use this bit to wake up from suspend for either the resume or the reset case. Reset this bit by writing a 1 to the clear address space and not by a general write.
9 ENIRQRESUMEDetect	Enables interrupt for detection of a non-J state on the USB line. This should only be enabled after the device has entered suspend mode.
8 RESUMEIRQSTICKY	Set to 1 will make RESUME_IRQ bit a sticky bit until software clear it. Set to 0, RESUME_IRQ only set during the wake-up period.
7 ENOTGIDDETECT	Enables circuit to detect resistance of MiniAB ID pin.
6 OTG_ID_CHG_IRQ	OTG ID change interrupt. Indicates the value of ID pin changed.
5 DEVPLUGIN_POLARITY	For device mode, if this bit is cleared to 0, then it trips the interrupt if the device is plugged in. If set to 1, then it trips the interrupt if the device is unplugged.
4 ENDEVPLUGINDETECT	For device mode, enables 200-KOhm pullups for detecting connectivity to the host.
3 HOSTDISCONDETECT_IRQ	Indicates that the device has disconnected in high-speed mode. Reset this bit by writing a 1 to the clear address space and not by a general write.
2 ENIRQHOSTDISCON	Enables interrupt for detection of disconnection to Device when in high-speed host mode. This should be enabled after ENDEVPLUGINDETECT is enabled.
1 ENHOSTDISCONDETECT	For host mode, enables high-speed disconnect detector. This signal allows the override of enabling the detection that is normally done in the UTMI controller. The UTMI controller enables this circuit whenever the host sends a start-of-frame packet.  SW shall set this bit when it found the high-speed device is connected, suggested during bus reset, after found high-speed device in USB_PORTSC1.PSPD).  SW shall make sure this bit is not set at the end of resume, otherwise a wrong disconnect status may be detected. Suggest clear it after set USB_PORTSC1.SUSP, set it again after resume is ended(USB_PORTSC1.FPR==0).
0 ENOTG_ID_CHG_IRQ	Enable OTG_ID_CHG_IRQ.

### 42.4.5 USB PHY Status Register (USBPHYx\_STATUS)

The USB PHY Status Register holds results of IRQ and other detects.

Address: Base address + 40h offset

## USB PHY Memory Map/Register Definition

### USBPHYx\_STATUS field descriptions

Field	Description
31–11 RSVD4	Reserved.
10 RESUME_STATUS	Indicates that the host is sending a wake-up after suspend and has triggered an interrupt.
9 RSVD3	Reserved.
8 OTGID_STATUS	Indicates the results of ID pin on MiniAB plug. False (0) is when ID resistance is less than Ra_Plug_ID, indicating host (A) side. True (1) is when ID resistance is greater than Rb_Plug_ID, indicating device (B) side.
7 RSVD2	Reserved.
6 DEVPLUGIN_STATUS	Indicates that the device has been connected on the USB_DP and USB_DM lines.
5–4 RSVD1	Reserved.
3 HOSTDISCONDETECT_STATUS	Indicates that the device has disconnected while in high-speed host mode.
RSVD0	Reserved.

### 42.4.6 USB PHY Debug Register (USBPHYx\_DEBUGn)

This register is used to debug the USB PHY.

Address: Base address + 50h offset + (4d × i), where i=0d to 3d

**USBPHYx\_DEBUGn field descriptions**

Field	Description
31 RSVD3	Reserved.
30 CLKGATE	Gate Test Clocks. Clear to 0 for running clocks. Set to 1 to gate clocks. Set this to save power while the USB is not actively being used. Configuration state is kept while the clock is gated.
29 HOST_RESUME_DEBUG	Choose to trigger the host resume SE0 with HOST_FORCE_LS_SE0 = 0 or UTMI_SUSPEND = 1.
28–25 SQUELCHRESETLENGTH	Duration of RESET in terms of the number of 480-MHz cycles.
24 ENSQUELCHRESET	Set bit to allow squelch to reset high-speed receive.
23–21 RSVD2	Reserved.
20–16 SQUELCHRESETCOUNT	Delay in between the detection of squelch to the reset of high-speed RX.
15–13 RSVD1	Reserved.
12 ENTX2RXCOUNT	Set this bit to allow a countdown to transition in between TX and RX.
11–8 TX2RXCOUNT	Delay in between the end of transmit to the beginning of receive. This is a Johnson count value and thus will count to 8.
7–6 RSVD0	Reserved.
5–4 ENHSTPULLDOWN	Set bit 5 to 1 to override the control of the USB_DP 15-KOhm pulldown. Set bit 4 to 1 to override the control of the USB_DM 15-KOhm pulldown. Clear to 0 to disable.
3–2 HSTPULLDOWN	Set bit 3 to 1 to pull down 15-KOhm on USB_DP line. Set bit 2 to 1 to pull down 15-KOhm on USB_DM line. Clear to 0 to disable.
1 DEBUG_INTERFACE_HOLD	Use holding registers to assist in timing for external UTMI interface.
0 OTGIDPIOLOCK	Once OTG ID from USBPHYx_STATUS_OTGID_STATUS, use this to hold the value. This is to save power for the comparators that are used to determine the ID status.

## 42.4.7 UTMI Debug Status Register 0 (USBPHYx\_DEBUG0\_STATUS)

The UTMI Debug Status Register 0 holds multiple views for counters and status of state machines. This is used in conjunction with the USBPHYx\_DEBUG1\_DBG\_ADDRESS field to choose which function to view. The default is described in the bit fields below and is used to count errors.

Address: Base address + 60h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0					
R	SQUELCH_COUNT						UTMI_RXERROR_FAIL_COUNT						LOOP_BACK_FAIL_COUNT																								
W	0																																				
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### USBPHYx\_DEBUG0\_STATUS field descriptions

Field	Description
31–26 SQUELCH_COUNT	Running count of the squelch reset instead of normal end for HS RX.
25–16 UTMI_RXERROR_FAIL_COUNT	Running count of the UTMI_RXERROR.
LOOP_BACK_FAIL_COUNT	Running count of the failed pseudo-random generator loopback. Each time entering testmode, counter goes to 900D and will count up for every detected packet failure in digital/analog loopback tests.

### 42.4.8 UTMI Debug Status Register 1 (USBPHYx\_DEBUG1n)

Chooses the muxing of the debug register to be shown in USBPHYx\_DEBUG0\_STATUS.

Address: Base address + 70h offset + (4d × i), where i=0d to 3d

#### USBPHYx\_DEBUG1n field descriptions

Field	Description
31–15 RSVD1	Reserved.
14–13 ENTAILADJVD	Delay increment of the rise of squelch: 00 = Delay is nominal 01 = Delay is +20% 10 = Delay is -20% 11 = Delay is -40%
RSVD0	Reserved. <b>Note:</b> This bit should remain clear.

## 42.4.9 UTMI RTL Version (USBPHYx\_VERSION)

Fields for RTL Version.

Address: Base address + 80h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
R	MAJOR								MINOR								STEP																	
W	0																																	
Reset	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### USBPHYx\_VERSION field descriptions

Field	Description
31–24 MAJOR	Fixed read-only value reflecting the MAJOR field of the RTL version.
23–16 MINOR	Fixed read-only value reflecting the MINOR field of the RTL version.
STEP	Fixed read-only value reflecting the stepping of the RTL version.

## 42.5 USB Analog Memory Map/Register Definition

### USB\_ANALOG memory map

## 42.5.1 USB VBUS Detect Register (USB\_ANALOG\_USB1\_VBUS\_DETECT $n$ )

This register defines controls for USB VBUS detect.

Address: 400D\_8000h base + 1A0h offset + (4d × i), where i=0d to 3d

**USB\_ANALOG\_USB1\_VBUS\_DETECT $n$  field descriptions**

Field	Description
31–28 -	This field is reserved. Reserved.
27 CHARGE_VBUS	USB OTG charge VBUS.
26 DISCHARGE_VBUS	USB OTG discharge VBUS.
25–21 -	This field is reserved. Reserved.
20 VBUSVALID_PWRUP_CMPS	Powers up comparators for vbus_valid detector.
19–3 -	This field is reserved. Reserved.
VBUSVALID_THRESH	Set the threshold for the VBUSVALID comparator. This comparator is the most accurate method to determine the presence of 5v, and includes hystersis to minimize the need for software debounce of the detection. This comparator has ~50mV of hystersis to prevent chattering at the comparator trip point.  000 <b>4V0</b> — 4.0V

Table continues on the next page...

**USB\_ANALOG\_USB1\_VBUS\_DETECT $n$  field descriptions (continued)**

Field	Description
001	<b>4V1</b> — 4.1V
010	<b>4V2</b> — 4.2V
011	<b>4V3</b> — 4.3V
100	<b>4V4</b> — 4.4V (default)
101	<b>4V5</b> — 4.5V
110	<b>4V6</b> — 4.6V
111	<b>4V7</b> — 4.7V

**42.5.2 USB Charger Detect Register (USB\_ANALOG\_USB1\_CHRG\_DETECT $n$ )**

This register defines controls for USB charger detect.

Address: 400D\_8000h base + 1B0h offset + (4d × i), where i=0d to 3d

**USB\_ANALOG\_USB1\_CHRG\_DETECT $n$  field descriptions**

Field	Description
31–24 -	This field is reserved. Reserved.

Table continues on the next page...

USB\_ANALOG\_USB1\_CHRG\_DETECT $n$  field descriptions (continued)

Field	Description
23 -	This field is reserved. Reserved.
22–21 -	This field is reserved. Reserved.
20 EN_B	Control the charger detector. 0 <b>ENABLE</b> — Enable the charger detector. 1 <b>DISABLE</b> — Disable the charger detector.
19 CHK_CHRG_B	Check the charger connection 0 <b>CHECK</b> — Check whether a charger (either a dedicated charger or a host charger) is connected to USB port. 1 <b>NO_CHECK</b> — Do not check whether a charger is connected to the USB port.
18 CHK_CONTACT	Check the contact of USB plug 0 <b>NO_CHECK</b> — Do not check the contact of USB plug. 1 <b>CHECK</b> — Check whether the USB plug has been in contact with each other
-	This field is reserved. Reserved.

### 42.5.3 USB VBUS Detect Status Register (USB\_ANALOG\_USB1\_VBUS\_DETECT\_STAT)

This register defines fields for USB VBUS Detect status.

Address: 400D\_8000h base + 1C0h offset = 400D\_81C0h

**USB\_ANALOG\_USB1\_VBUS\_DETECT\_STAT field descriptions**

Field	Description
31-4 -	This field is reserved. Reserved.

*Table continues on the next page...*

**USB\_ANALOG\_USB1\_VBUS\_DETECT\_STAT field descriptions (continued)**

<b>Field</b>	<b>Description</b>
3 VBUS_VALID	VBus valid for USB OTG. This bit is a read only version of the state of the analog signal. It can not be overwritten by software.
2 AVALID	Indicates VBus is valid for a A-peripheral. This bit is a read only version of the state of the analog signal. It can not be overwritten by software.
1 BVALID	Indicates VBus is valid for a B-peripheral. This bit is a read only version of the state of the analog signal. It can not be overwritten by software.
0 SESSEND	Session End for USB OTG. This bit is a read only version of the state of the analog signal. It can not be overwritten by software like the SESSEND bit below.  NOTE: This bit's default value depends on whether VDD5V is present, 0 if VDD5V is present, 1 if VDD5V is not present.

## 42.5.4 USB Charger Detect Status Register (USB\_ANALOG\_USB1\_CHRG\_DETECT\_STAT)

This register defines fields for USB charger detect status.

Address: 400D\_8000h base + 1D0h offset = 400D\_81D0h

**USB\_ANALOG\_USB1\_CHRG\_DETECT\_STAT field descriptions**

Field	Description
31–4 -	This field is reserved. Reserved.
3 DP_STATE	DP line state output of the charger detector.
2 DM_STATE	DM line state output of the charger detector.
1 CHRG_DETECTED	State of charger detection. This bit is a read only version of the state of the analog signal. 0 <b>CHARGER_NOT_PRESENT</b> — The USB port is not connected to a charger. 1 <b>CHARGER_PRESENT</b> — A charger (either a dedicated charger or a host charger) is connected to the USB port.
0 PLUG_CONTACT	State of the USB plug contact detector. 0 <b>NO_CONTACT</b> — The USB plug has not made contact. 1 <b>GOOD_CONTACT</b> — The USB plug has made good contact.

**42.5.5 USB Misc Register (USB\_ANALOG\_USB1\_MISCn)**

This register defines controls for USB.

Address: 400D\_8000h base + 1F0h offset + (4d × i), where i=0d to 3d

**USB\_ANALOG\_USB1\_MISC<sub>n</sub> field descriptions**

Field	Description
31 -	This field is reserved. Reserved.
30 EN_CLK_UTMI	Enables the clk to the UTMI block.
29–2 -	This field is reserved. Reserved.
1 EN_DEGLITCH	Enable the deglitching circuit of the USB PLL output.
0 HS_USE_EXTERNAL_R	Use external resistor to generate the current bias for the high speed transmitter. This bit should not be changed unless recommended by NXP.

**42.5.6 USB VBUS Detect Register (USB\_ANALOG\_USB2\_VBUS\_DETECT<sub>n</sub>)**

This register defines controls for USB VBUS detect.

Address: 400D\_8000h base + 200h offset + (4d × i), where i=0d to 3d

**USB\_ANALOG\_USB2\_VBUS\_DETECT<sub>n</sub> field descriptions**

Field	Description
31–28 -	This field is reserved. Reserved.

Table continues on the next page...

USB\_ANALOG\_USB2\_VBUS\_DETECT $n$  field descriptions (continued)

Field	Description
27 CHARGE_VBUS	USB OTG charge VBUS.
26 DISCHARGE_VBUS	USB OTG discharge VBUS.
25–21 -	This field is reserved. Reserved.
20 VBUSVALID_PWRUP_CMPS	Powers up comparators for vbus_valid detector.
19–3 -	This field is reserved. Reserved.
VBUSVALID_THRESH	Set the threshold for the VBUSVALID comparator. This comparator is the most accurate method to determine the presence of 5v, and includes hysteresis to minimize the need for software debounce of the detection. This comparator has ~50mV of hysteresis to prevent chattering at the comparator trip point.  000 <b>4V0</b> — 4.0V 001 <b>4V1</b> — 4.1V 010 <b>4V2</b> — 4.2V 011 <b>4V3</b> — 4.3V 100 <b>4V4</b> — 4.4V (default) 101 <b>4V5</b> — 4.5V 110 <b>4V6</b> — 4.6V 111 <b>4V7</b> — 4.7V

## 42.5.7 USB Charger Detect Register (USB\_ANALOG\_USB2\_CHRG\_DETECT $n$ )

This register defines controls for USB charger detect.

Address: 400D\_8000h base + 210h offset + (4d × i), where i=0d to 3d

**USB\_ANALOG\_USB2\_CHRG\_DETECT $n$  field descriptions**

Field	Description
31–24 -	This field is reserved. Reserved.
23 -	This field is reserved. Reserved.
22–21 -	This field is reserved. Reserved.
20 EN_B	Control the charger detector. 0 <b>ENABLE</b> — Enable the charger detector. 1 <b>DISABLE</b> — Disable the charger detector.
19 CHK_CHRG_B	Check the charger connection

*Table continues on the next page...*

**USB\_ANALOG\_USB2\_CHRG\_DETECT $n$  field descriptions (continued)**

Field	Description
	0 <b>CHECK</b> — Check whether a charger (either a dedicated charger or a host charger) is connected to USB port. 1 <b>NO_CHECK</b> — Do not check whether a charger is connected to the USB port.
18 CHK_CONTACT	Check the contact of USB plug 0 <b>NO_CHECK</b> — Do not check the contact of USB plug. 1 <b>CHECK</b> — Check whether the USB plug has been in contact with each other
-	This field is reserved. Reserved.

## 42.5.8 USB VBUS Detect Status Register (USB\_ANALOG\_USB2\_VBUS\_DETECT\_STAT)

This register defines fields for USB VBUS Detect status.

Address: 400D\_8000h base + 220h offset = 400D\_8220h

**USB\_ANALOG\_USB2\_VBUS\_DETECT\_STAT field descriptions**

Field	Description
31–4 -	This field is reserved. Reserved.

*Table continues on the next page...*

**USB\_ANALOG\_USB2\_VBUS\_DETECT\_STAT field descriptions (continued)**

<b>Field</b>	<b>Description</b>
3 VBUS_VALID	VBus valid for USB OTG. This bit is a read only version of the state of the analog signal. It can not be overwritten by software.
2 AVALID	Indicates VBus is valid for a A-peripheral. This bit is a read only version of the state of the analog signal. It can not be overwritten by software.
1 BVALID	Indicates VBus is valid for a B-peripheral. This bit is a read only version of the state of the analog signal. It can not be overwritten by software.
0 SESSEND	Session End for USB OTG. This bit is a read only version of the state of the analog signal. It can not be overwritten by software like the SESSEND bit below.  NOTE: This bit's default value depends on whether VDD5V is present, 0 if VDD5V is present, 1 if VDD5V is not present.

## 42.5.9 USB Charger Detect Status Register (USB\_ANALOG\_USB2\_CHRG\_DETECT\_STAT)

This register defines fields for USB charger detect status.

Address: 400D\_8000h base + 230h offset = 400D\_8230h

**USB\_ANALOG\_USB2\_CHRG\_DETECT\_STAT field descriptions**

Field	Description
31–4 -	This field is reserved. Reserved.
3 DP_STATE	DP line state output of the charger detector.
2 DM_STATE	DM line state output of the charger detector.
1 CHRG_DETECTED	State of charger detection. This bit is a read only version of the state of the analog signal. 0 <b>CHARGER_NOT_PRESENT</b> — The USB port is not connected to a charger. 1 <b>CHARGER_PRESENT</b> — A charger (either a dedicated charger or a host charger) is connected to the USB port.
0 PLUG_CONTACT	State of the USB plug contact detector. 0 <b>NO_CONTACT</b> — The USB plug has not made contact. 1 <b>GOOD_CONTACT</b> — The USB plug has made good contact.

**42.5.10 USB Misc Register (USB\_ANALOG\_USB2\_MISCn)**

This register defines controls for USB.

Address: 400D\_8000h base + 250h offset + (4d × i), where i=0d to 3d

**USB\_ANALOG\_USB2\_MISCn field descriptions**

Field	Description
31 -	This field is reserved. Reserved.
30 EN_CLK_UTMI	Enables the clk to the UTMI block.
29–2 -	This field is reserved. Reserved.
1 EN_DEGLITCH	Enable the deglitching circuit of the USB PLL output.
0 HS_USE_EXTERNAL_R	Use external resistor to generate the current bias for the high speed transmitter. This bit should not be changed unless recommended by NXP.

**42.5.11 Chip Silicon Version (USB\_ANALOG\_DIGPROG)**

The DIGPROG register returns the digital program ID for the silicon.

Address: 400D\_8000h base + 260h offset = 400D\_8260h

**USB\_ANALOG\_DIGPROG field descriptions**

Field	Description
SILICON_REVISION	Chip silicon revision 0x006C0000 Silicon revision 1.0

# Chapter 43

## Flexible Controller Area Network (FLEXCAN)

### 43.1 Chip-specific FLEXCAN information

### 43.2 Overview

The Flexible Controller Area Network (FLEXCAN) module is a communication controller implementing the CAN protocol according to the CAN 2.0B protocol specification.

The CAN protocol was primarily designed to be used as a vehicle serial data bus meeting the specific requirements of this field: real-time processing, reliable operation in the EMI environment of a vehicle, cost-effectiveness and required bandwidth. The FLEXCAN module is a full implementation of the CAN protocol specification, which supports both standard and extended message frames. 64 Message Buffers are supported by the Flexcan module.

## 43.2.1 Block Diagram

A general block diagram is shown in the figure below, which describes the main sub-blocks implemented in the FLEXCAN module, including the associated memory for storing Mailboxes, Rx Global Mask Registers, Rx Individual Mask Registers, Rx FIFO and Rx FIFO ID Filters.

Support for 64 Mailboxes and 6-deep Rx FIFO is provided. The functions of the sub-modules are described in subsequent sections.

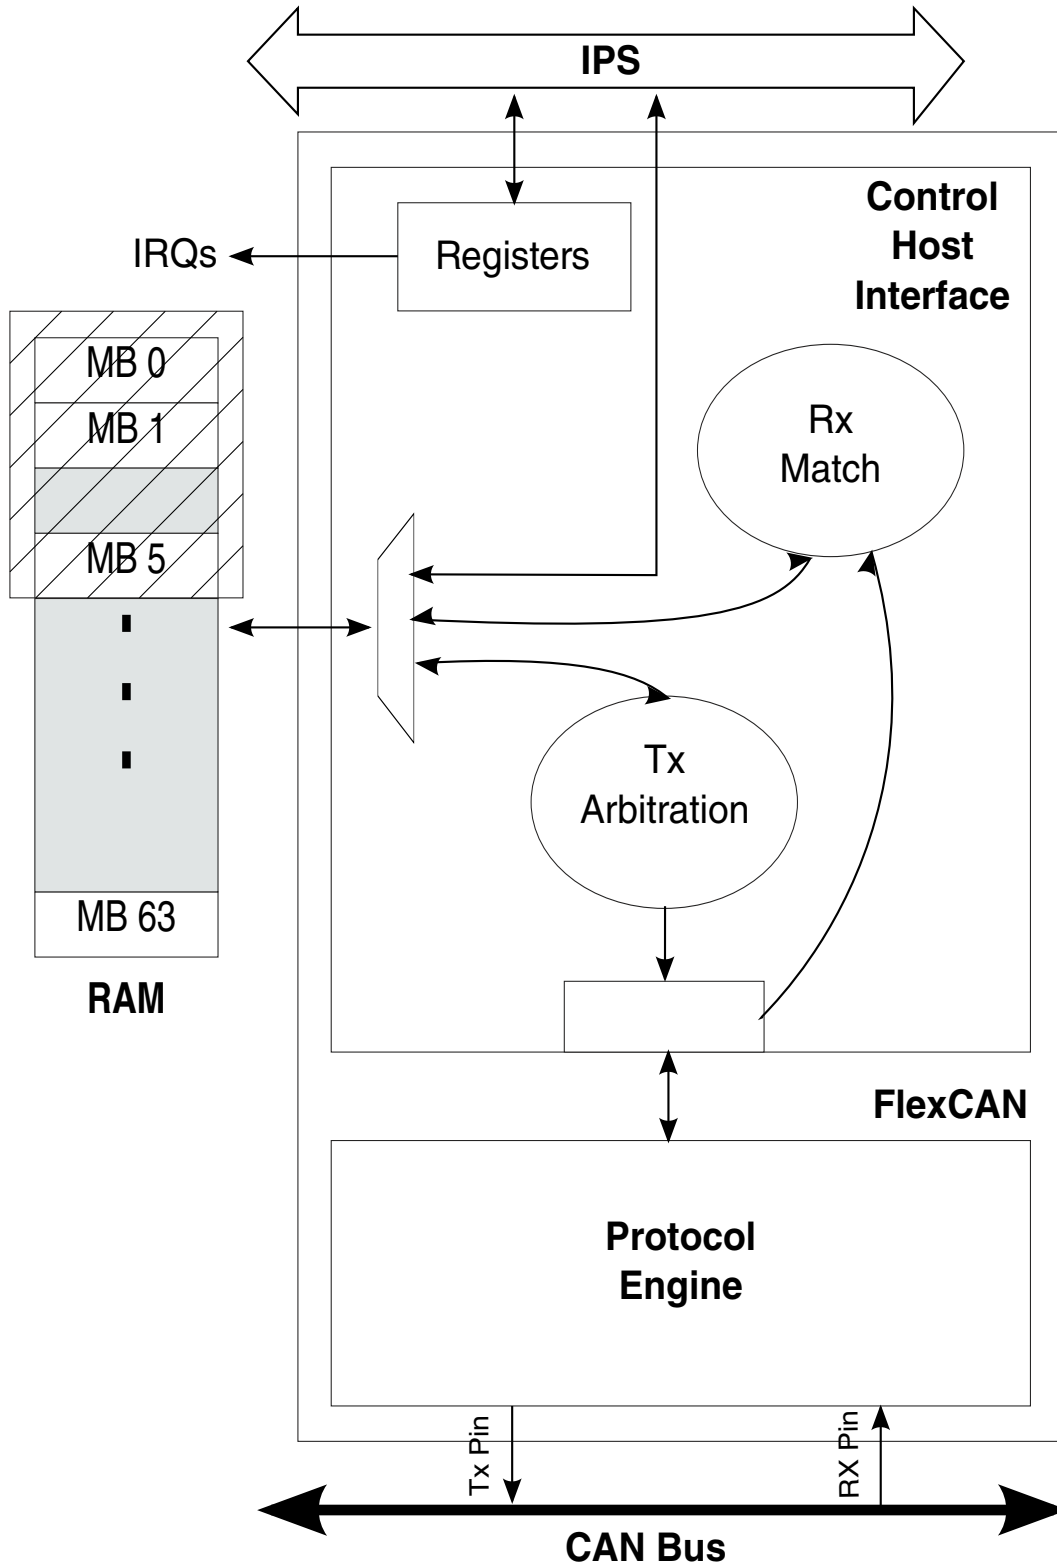

Figure 43-1. FLEXCAN Block Diagram

## 43.2.2 FLEXCAN Module Features

The FLEXCAN module includes these distinctive legacy features:

- Version 2.0B
  - Standard data and remote frames
  - Extended data and remote frames
  - Zero to eight bytes data length
  - Programmable bit rate up to 1 Mb/sec
  - Content-related addressing
- Flexible Mailboxes of eight bytes data length
- Each Mailbox is configurable as Rx or Tx, all supporting standard and extended messages
- Individual Rx Mask Registers per Mailbox
- Full featured Rx FIFO with storage capacity for 6 frames and internal pointer handling
- Transmission abort capability
- Powerful Rx FIFO ID filtering, capable of matching incoming IDs against either 128 extended, 256 standard or 512 partial (8 bits) IDs, with up to 32 individual masking capability
- 100% backwards compatibility with previous FLEXCAN version
- Unused structures space can be used as general purpose RAM space
- Listen only mode capability
- Programmable loop-back mode supporting self-test operation
- Programmable transmission priority scheme: lowest ID, lowest buffer number or highest priority
- Time Stamp based on 16-bit free-running timer
- Global network time, synchronized by a specific message
- Maskable interrupts independent of the transmission medium (an external transceiver is assumed)
- Short latency time due to an arbitration scheme for high-priority messages
- Low power modes, with programmable wake up on bus activity
- Configurable Glitch filter width to filter the noise on CAN bus when waking up
- Remote request frames may be handled automatically or by software.
- ID filter configuration in Normal Mode
- CAN bit time settings and configuration bits can only be written in Freeze Mode
- Tx mailbox status (Lowest priority buffer or empty buffer)
- SYNC bit status to inform that the module is synchronous with CAN bus
- CRC status for transmitted message
- Selectable priority between Mailboxes and Rx FIFO during matching process

### 43.2.3 Modes of Operation

The FLEXCAN module has four functional modes: Normal Mode (User and Supervisor), Freeze Mode, Listen-Only Mode and Loop-Back Mode. There are also two low power modes: Disable Mode and Stop Mode.

- Normal Mode (User or Supervisor):

In Normal Mode, the module operates receiving and/or transmitting message frames, errors are handled normally and all the CAN Protocol functions are enabled. User and Supervisor Modes differ in the access to some restricted control registers.

- Freeze Mode:

It is enabled when the FRZ bit in the MCR Register is asserted. If enabled, Freeze Mode is entered when the HALT bit in MCR is set or when Debug Mode is requested at MCU level and the FRZ\_ACK bit in the MCR Register is asserted by the FlexCAN. In this mode, no transmission or reception of frames is done and synchronicity to the CAN bus is lost. See [Freeze Mode](#) for more information.

- Listen-Only Mode:

The module enters this mode when the LOM bit in the Control Register is asserted. In this mode, transmission is disabled, all error counters are frozen and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station will be received. If FLEXCAN detects a message that has not been acknowledged, it will flag a BIT0 error (without changing the REC), as if it was trying to acknowledge the message.

- Loop-Back Mode:

The module enters this mode when the LPB bit in the Control Register is asserted. In this mode, FLEXCAN performs an internal loop back that can be used for self test operation. The bit stream output of the transmitter is internally fed back to the receiver input. The FLEXCAN\_RX input pin is ignored and the FLEXCAN\_TX output goes to the recessive state (logic '1'). FLEXCAN behaves as it normally does when transmitting and treats its own transmitted message as a message received from a remote node. In this mode, FLEXCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field to ensure proper reception of its own message. Both transmit and receive interrupts are generated.

- Module Disable Mode:

This low power mode is entered when the MDIS bit in the MCR Register is asserted and the LPM\_ACK is asserted by the FlexCAN. When disabled, the module requests to disable the clocks to the CAN Protocol Engine and Controller Host Interface sub-modules. Exit from this mode is done by negating the MDIS bit in the MCR Register. See [Module Disable Mode](#) for more information.

- Stop Mode:

This low power mode is entered when Stop Mode is requested at Arm level and the LPM\_ACK bit in the MCR Register is asserted by the FlexCAN. When in Stop Mode, the module puts itself in an inactive state and then informs the Arm that the clocks can be shut down globally. Exit from this mode happens when the Stop Mode request is removed or when activity is detected on the CAN bus and the Self Wake Up mechanism is enabled. See [Stop Mode](#) for more information.

### 43.3 External Signals

The FLEXCAN module has two I/O signals.

**Table 43-2. FLEXCAN External Signals**

Signal	Description	Pad	Mode	Direction
FLEXCAN1_RX	FLEXCAN receive pin. This pin is the receive pin from the CAN bus transceiver. Dominant state is represented by logic level '0'. Recessive state is represented by logic level '1'.	GPIO_AD_B1_08	ALT2	I
		GPIO_B0_02	ALT2	
		GPIO_EMCC_17	ALT3	
		GPIO_SD_B1_02	ALT4	
FLEXCAN1_TX	FLEXCAN transmit pin. This pin is the transmit pin to the CAN bus transceiver. Dominant state is represented by logic level '0'. Recessive state is represented by logic level '1'.	GPIO_AD_B1_09	ALT2	O
		GPIO_B0_03	ALT2	
		GPIO_EMCC_18	ALT3	
		GPIO_SD_B1_03	ALT4	
FLEXCAN2_RX	FLEXCAN transmit pin. This pin is the transmit pin to the CAN bus transceiver. Dominant state is represented by logic level '0'. Recessive state is represented by logic level '1'.	GPIO_AD_B0_03	ALT0	I
		GPIO_EMCC_10	ALT3	
		GPIO_AD_B0_15	ALT6	
		GPIO_B1_09	ALT6	

Table continues on the next page...

**Table 43-2. FLEXCAN External Signals  
(continued)**

FLEXCAN2_TX	FLEXCAN receive pin. This pin is the receive pin from the CAN bus transceiver. Dominant state is represented by logic level '0'. Recessive state is represented by logic level '1'.	GPIO_AD_B0_02	ALT0	O
		GPIO_EMC_09	ALT3	
		GPIO_B1_08	ALT6	
		GPIO_AD_B0_14	ALT6	
FLEXCAN3_RX	FLEXCAN transmit pin. This pin is the transmit pin to the CAN bus transceiver. Dominant state is represented by logic level '0'. Recessive state is represented by logic level '1'.	GPIO_AD_B0_11	ALT8	I
		GPIO_AD_B0_15	ALT8	
		GPIO_EMC_37	ALT9	
FLEXCAN3_TX	FLEXCAN receive pin. This pin is the receive pin from the CAN bus transceiver. Dominant state is represented by logic level '0'. Recessive state is represented by logic level '1'.	GPIO_AD_B0_10	ALT8	O
		GPIO_AD_B0_14	ALT8	
		GPIO_EMC_36	ALT9	

## 43.4 Clocks

The table found here describes the clock sources for FLEXCAN.

Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

**Table 43-3. FLEXCAN Clocks**

Clock name	Clock Root	Description
ipg_clk	ipg_clk_root	Peripheral clock
ipg_clk_chi	ipg_clk_root	CHI clock
ipg_clk_pe	can_clk_root	Protocol Engine clock
ipg_clk_pe_nogate	can_clk_root	Protocol Engine clock (no gating)
ipg_clk_s	ipg_clk_root	Peripheral access clock
mem_ram_CLK	ipg_clk_root	RAM clock

## 43.5 Message Buffer Structure

Message Buffer Address: Base + 0x0080-0x047C.

The Message Buffer structure used by the FLEXCAN module is represented in the following table.

Both Extended and Standard Frames (29-bit Identifier and 11-bit Identifier, respectively) used in the CAN specification are represented.

Each individual Message buffer is formed by 16 bytes.

**Table 43-4. Message Buffer Structure**

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x0					CODE					S R R	I D E	R T R	DLC				TIME STAMP															
0x4	PRIO		ID Standard								ID Extended																					
0x8	DATA BYTE 0				DATA BYTE 1				DATA BYTE 2				DATA BYTE 3																			
0xC	DATA BYTE 4				DATA BYTE 5				DATA BYTE 6				DATA BYTE 7																			

### CODE - Message Buffer Code

This 4-bit field can be accessed (read or write) by the CPU and by the FLEXCAN module itself, as part of the message buffer matching and arbitration process. The encoding is shown in the following tables. See [Functional Description](#) for additional information.

**Table 43-5. Message Buffer Code for Rx buffers**

CODE Description	Rx Code BEFORE receive New Frame	SRV <sup>1</sup>	Rx Code AFTER successful reception <sup>2</sup>	RRS <sup>3</sup>	Comment
0b0000: INACTIVE- MB is not active.	INACTIVE	-	-	-	MB does not participate in the matching process.
0b0100: EMPTY - MB is active and empty.	EMPTY	-	FULL	-	When a frame is received successfully (after move-in process. Refer to <a href="#">Move-in</a> for details), the CODE field is automatically updated to FULL.
0b0010: FULL - MB is full.	FULL	Yes	FULL	-	The act of reading the C/S word followed by unlocking the MB (SRV) does not make the code return to EMPTY. It remains FULL. If a

*Table continues on the next page...*

Table 43-5. Message Buffer Code for Rx buffers (continued)

CODE Description	Rx Code BEFORE receive New Frame	SRV <sup>1</sup>	Rx Code AFTER successful reception <sup>2</sup>	RRS <sup>3</sup>	Comment
					new frame is moved to the MB after the MB was serviced, the code still remains FULL. Refer to <a href="#">Matching Process</a> for matching details related to FULL code.
		No	OVERRUN	-	If the MB is FULL and a new frame is moved to this MB before the CPU services it, the CODE field is automatically updated to OVERRUN. Refer to <a href="#">Matching Process</a> for details about overrun behavior.
0b0110: OVERRUN - MB is being overwritten into a full buffer.	OVERRUN	Yes	FULL	-	If the CODE field indicates OVERRUN and CPU has serviced the MB, when a new frame is moved to the MB, the code returns to FULL.
		No	OVERRUN	-	If the CODE field already indicates OVERRUN, and another new frame must be moved, the MB will be overwritten again, and the code will remain OVERRUN. Refer to <a href="#">Matching Process</a> for details about overrun behavior.
0b1010: RANSWER <sup>4</sup> - A frame was configured to recognize a Remote Request Frame and transmit a Response Frame in return.	RANSWER	-	TANSWER(0b1110)	0	A Remote Answer was configured to recognize a remote request frame received, after that a MB is set to transmit a response frame. The code is automatically changed to TANSWER (0b1110). Refer to <a href="#">Matching Process</a> for details.  If CTRL2[RRS] is negated, transmit a response frame whenever a remote request frame with the same ID is received.
			-	1	This code is ignored during matching and arbitration process. Refer to <a href="#">Matching Process</a> for details.
CODE[0]=1b1: BUSY - FlexCAN is updating the contents of the MB. The CPU must not access the MB.	BUSY <sup>5</sup>	-	FULL	-	Indicates that the MB is being updated, it will be negated automatically and does not interfere on the next CODE.
			OVERRUN	-	

1. SRV: Serviced MB. MB was read and unlocked by reading TIMER or other MB.
2. A frame is considered successful reception after the frame to be moved to MB (move-in process). Refer to [Move-in](#) for details)
3. Remote Request Stored bit from CTRL2 register. Refer to [CTRL2](#) for details.
4. Code 4'b1010 is not considered as a Tx and a MB with this code should not to be aborted.
5. Note that for Tx MBs, the BUSY bit should be ignored upon read, except when AEN bit is set in the MCR register. If this bit is asserted, the corresponding MB does not participate in the matching process.

**Table 43-6. Message Buffer Code for Tx buffers**

CODE Description	Tx Code BEFORE tx frame	MB RTR	Tx Code AFTER successful transmission	Comment
0b1000: INACTIVE - MB is not active	INACTIVE	-	-	MB does not participate in the arbitration process.
0b1001: ABORT - MB is aborted	ABORT	-	-	MB does not participate in the arbitration process.
0b1100: DATA - MB is a Tx Data Frame (MB RTR must be 0)	DATA	0	INACTIVE	Transmit data frame unconditionally once. After transmission, the MB automatically returns to the INACTIVE state.
0b1100: REMOTE - MB is a Tx Remote Request Frame (MB RTR must be 1)	REMOTE	1	EMPTY	Transmit remote request frame unconditionally once. After transmission, the MB automatically becomes an Rx Empty MB with the same ID.
0b1110: TANSWER - MB is a Tx Response Frame from an incoming Remote Request Frame	TANSWER	-	RANSWER	This is an intermediate code that is automatically written to the MB by the CHI as a result of match to a remote request frame. The remote response frame will be transmitted unconditionally once and then the code will automatically return to RANSWER (0b1010). The CPU can also write this code with the same effect.  The remote response frame can be either a data frame or another remote request frame depending on the RTR bit value. Refer to <a href="#">Matching Process</a> and <a href="#">Arbitration process</a> for details.

**SRR - Substitute Remote Request**

Fixed recessive bit, used only in extended format. It must be set to '1' by the user for transmission (Tx Buffers) and will be stored with the value received on the CAN bus for Rx receiving buffers. It can be received as either recessive or dominant. If FLEXCAN receives this bit as dominant, then it is interpreted as arbitration loss.

1= Recessive value is compulsory for transmission in Extended Format frames

0= Dominant is not a valid value for transmission in Extended Format frames

**IDE - ID Extended Bit**

This bit identifies whether the frame format is standard or extended. It is also used as part of the reception filter.

1= Frame format is extended

0= Frame format is standard

**RTR - Remote Transmission Request**

This bit affects the behavior of Remote Frames and is part of the reception filter. Refer to the tables above and RRS bit in [Control 2 Register \(FLEXCAN\\_CTRL2\)](#) for additional details.

If FLEXCAN transmits this bit as '1' (recessive) and receives it as '0' (dominant), it is interpreted as arbitration loss. If this bit is transmitted as '0' (dominant), then if it is received as '1' (recessive), the FLEXCAN module treats it as bit error. If the value received matches the value transmitted, it is considered as a successful bit transmission.

1= Indicates the current MB has a Remote Frame to be transmitted if MB is Tx. If the MB is Rx then incoming Remote Request Frames may be stored.

0= Indicates the current MB has a Data Frame to be transmitted. In Rx MB it may be considered in matching processes.

**DLC - Length of Data in Bytes**

This 4-bit field is the length (in bytes) of the Rx or Tx data, which is located in offset 0x08 through 0x0F of the MB space (see the first table above). In reception, this field is written by the FLEXCAN module, copied from the DLC (Data Length Code) field of the received frame. In transmission, this field is written by the Arm and corresponds to the DLC field value of the frame to be transmitted. When RTR=1, the Frame to be transmitted is a Remote Frame and does not include the data field, regardless of the Length field. The DLC field indicates which DATA BYTEs are valid as shown in the table below.

**TIME STAMP - Free-Running Counter Time Stamp**

This 16-bit field is a copy of the Free-Running Timer, captured for Tx and Rx frames at the time when the beginning of the Identifier field appears on the CAN bus.

**PRIO - Local priority**

This 3-bit field is only used when MCR[LPRIO\_EN] bit is asserted and it only makes sense for Tx mailboxes. These bits are not transmitted. They are appended to the regular ID to define the transmission priority. See [Arbitration process](#).

**ID - Frame Identifier**

In Standard Frame format, only the 11 most significant bits (28 to 18) are used for frame identification in both receive and transmit cases. The 18 least significant bits are ignored. In Extended Frame format, all bits are used for frame identification in both receive and transmit cases.

**DATA BYTE 0-7 - Data Field**

Up to eight bytes can be used for a data frame.

For Rx frames, the data is stored as it is received from the CAN bus. DATA BYTE ( $n$ ) is valid only if  $n$  is less than DLC as shown in the table below.

For Tx frames, the CPU prepares the data field to be transmitted within the frame.

**Table 43-7. DATA BYTEs validity**

DLC	Valid DATA BYTEs
0	none
1	DATA BYTE 0
2	DATA BYTE 0-1
3	DATA BYTE 0-2
4	DATA BYTE 0-3
5	DATA BYTE 0-4
6	DATA BYTE 0-5
7	DATA BYTE 0-6
8	DATA BYTE 0-7

## 43.6 Rx FIFO Structure

When the MCR[RFEN] bit is set, the memory area from 0x80 to 0xDC (which is normally occupied by MBs 0 to 5) is used by the reception FIFO engine.

The region 0x80-0x8C contains the output of the FIFO which must be read by the CPU as a Message Buffer. This output contains the oldest message received and not read yet. The region 0x90-0xDC is reserved for internal use of the FIFO engine.

An additional memory area, that starts at 0xE0 and may extend up to 0x2DC (normally occupied by MBs 6 up to 37) depending on the CTRL2[RFFN] field setting, contains the ID Filter Table (configurable from 8 to 128 memory positions) that specifies filtering criteria for accepting frames into the FIFO. [Table 43-8](#) shows the Rx FIFO data structure.

Each ID Filter Table Element occupies an entire 32-bit word and can be compounded by one, two or four Identifier Acceptance Filters (IDAF) depending on the MCR[IDAM] field setting. [Table 43-9](#), [Table 43-10](#) and [Table 43-11](#) show the IDAF indexation. [Table 43-12](#) show the three different formats that the IDAF can assume, depending on the MCR[IDAM] field setting. Note that all elements of the table must have the same format. See [Rx FIFO](#) for more information.

Out of reset, the ID Filter Table flexible memory area defaults to 0xE0 and only extends to 0xFC, which corresponds to MBs 6 to 7 for RFFN=0.

### RXIDA - Rx Frame Identifier (Format A)

Specifies an ID to be used as acceptance criteria for the FIFO. In the Standard Format (IDAF's or incoming frame's IDE bit is negated), only the 11 most significant bits (29 to 19 ) are used for frame identification. In the Extended Format (both IDAF's and incoming frame's IDE are asserted), all bits are used.

### RXIDB\_0, RXIDB\_1 - Rx Frame Identifier (Format B)

Specifies an ID to be used as acceptance criteria for the FIFO. In the Standard Format (IDAF's or incoming frame's IDE bit is negated), the 11 most significant bits (29 to 19 and 13 to 3 ) are used for frame identification. In the Extended Format (both IDAF's and incoming frame's IDE are asserted), all 14 bits of the field are compared with the 14 most significant bits of the Identifier of the incoming frame. The 15 least significant bits of the Identifier of an incoming Extended Format frame do not affect the acceptance.

### RXIDC\_0, RXIDC\_1, RXIDC\_2, RXIDC\_3 - Rx Frame Identifier (Format C)

Specifies an ID to be used as acceptance criteria for the FIFO. In both Standard Format and Extended Format, all 8 bits of the field are compared to the 8 most significant bits of the Identifier of the incoming frame. The 3 least significant bits of the Identifier of an incoming Standard Format frame and the 21 least significant bits of the Identifier of an incoming Extended Format frame do not affect the acceptance.

## 43.7 Functional Description

This section provides a complete functional description of the block.

### 43.7.1 Functional Overview

The FLEXCAN module is a CAN protocol engine with a very flexible mailbox system for transmitting and receiving CAN frames. The mailbox system consists of a set of 64 Message Buffers (MB) that store configuration and control data, time stamp, message ID and data (see [Message Buffer Structure](#)). The memory corresponding to the first 38 MBs can be configured to support a FIFO reception scheme with a powerful ID filtering mechanism, capable of checking incoming frames against a table of IDs (up to 128 extended IDs or 256 standard IDs or 512 8-bit ID slices), with individual mask register for up to 32 ID Filter Table elements. Simultaneous reception through FIFO and mailbox is supported. For mailbox reception, a *matching* algorithm makes it possible to store received frames only into MBs that have the same ID. A masking scheme makes it possible to match the ID programmed on the MB with a range of Identifiers on received

CAN frames. For transmission, an *arbitration* algorithm decides the prioritization of MBs to be transmitted based on the message ID (optionally augmented by 3 local priority bits) or the MB ordering.

Before proceeding with the functional description, an important concept must be explained. A Message Buffer is said to be "active" at a given time if it can participate in both the Matching and Arbitration processes. An Rx MB with a 0b0000 code is inactive (refer to [Table 43-5](#)). Similarly, a Tx MB with a 0b1000 or 0b1001 code is also inactive (refer to [Table 43-6](#)).

## 43.7.2 Transmit Process

In order to transmit a CAN frame, the CPU must prepare a Message Buffer for transmission by executing the procedure found here.

1. Check if the respective interruption bit is set and clear it.
2. If the MB is active (transmission pending), write the ABORT code (0b1001) to the CODE field of the Control and Status word to request an abortion of the transmission. Wait for the corresponding IFLAG to be asserted by polling the IFLAG register or by the interrupt request if enabled by the respective IMASK. Then read back the CODE field to check if the transmission was aborted or transmitted (see [Transmission Abort Mechanism](#)). If backwards compatibility is desired (MCR[AEN] bit negated), just write the INACTIVE code (0b1000) to the CODE field to inactivate the MB but then the pending frame may be transmitted without notification (see [Message Buffer Inactivation](#)).
3. Write the ID word.
4. Write the data bytes.
5. Write the DLC, Control and Code fields of the Control and Status word to activate the MB.

Once the MB is activated, it will participate into the arbitration process and eventually be transmitted according to its priority.

At the end of the successful transmission, the value of the Free Running Timer at the time of the second bit of frame's Identifier field is written into the MB's Time Stamp field, the CODE field in the Control and Status word is updated, the CRC Register is updated, a status flag is set in the Interrupt Flag Register and an interrupt is generated if allowed by the corresponding Interrupt Mask Register bit. The new CODE field after transmission depends on the code that was used to activate the MB in step four (see [Table 43-5](#) and [Table 43-6](#) in [Message Buffer Structure](#)).

When the Abort feature is enabled (MCR[AEN] bit is asserted), after the Interrupt Flag is asserted for a Mailbox configured as transmit buffer, the Mailbox is blocked, therefore the CPU is not able to update it until it negates the Interrupt Flag. It means that the CPU must clear the corresponding IFLAG before starting to prepare this MB for a new transmission or reception.

### 43.7.3 Arbitration process

The arbitration process scans the Mailboxes searching the Tx one that holds the message to be sent in the next opportunity. This Mailbox is called the *arbitration winner*.

The scan starts from the lowest Mailbox number and runs toward the higher ones.

The arbitration process is triggered in the following events:

- From the CRC field of the CAN frame. The start point depends on the CTRL2[TASD] field value. See [Control 2 Register \(FLEXCAN\\_CTRL2\)](#) for details.
- During the error delimiter field of the CAN frame
- During the Overload Delimiter field of a CAN frame.
- When the winner is inactivated and the CAN bus has still not reached the first bit of the Intermission field.
- When Arm write to the C/S word of a winner MB and the CAN bus has still not reached the first bit of the Intermission field.
- When CHI is in Idle state and Arm writes to the C/S word of any MB.
- When FlexCAN exits Bus Off state
- Upon leaving Freeze Mode or Low Power Mode

If the arbitration process does not manage to evaluate all Mailboxes before the CAN bus has reached the first bit of the Intermission field the temporary arbitration winner is invalidated and the FlexCAN will not compete for the CAN bus in the next opportunity.

The arbitration process selects the winner among the active Tx Mailboxes at the end of the scan according to both CTRL1[LBUF] and MCR[LPRIO\_EN] bits settings.

#### 43.7.3.1 Lowest Mailbox number first

If CTRL1[LBUF] bit is asserted the first (lowest number) active Tx Mailbox found is the arbitration winner. MCR[LPRIO\_EN] bit has no effect when CTRL1[LBUF] is asserted.

### 43.7.3.2 Highest Mailbox priority first

If CTRL1[LBUF] bit is negated then the arbitration process searches the active Tx Mailbox with the highest priority, and this Mailbox would have a higher probability to win the arbitration on CAN bus.

The sequence of bits considered for this arbitration is called the *arbitration value* of the Mailbox. The highest priority Tx Mailbox is the one that has the least arbitration value among all Tx Mailboxes.

If two or more Mailboxes have equivalent arbitration values the lowest Mailbox number is the arbitration winner.

The composition of the arbitration value depends on MCR[LPRIO\_EN] bit setting.

#### 43.7.3.2.1 Local Priority disabled

If MCR[LPRIO\_EN] bit is negated the arbitration value is built in the exact sequence of bits as they would be transmitted in a CAN frame (see [Table 43-13](#)) in such a way that the Local Priority is disabled.

**Table 43-13. Composition of the arbitration value when Local Priority is disabled**

Format	Mailbox Arbitration Value (32 bits)				
Standard (IDE = 0)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	- (18 bits)	- (1 bit)
Extended (IDE = 1)	Extended ID[28:18 ] (11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0 ] (18 bits)	RTR (1 bit)

#### 43.7.3.2.2 Local Priority enabled

If Local Priority is desired MCR[LPRIO\_EN] must be asserted.

In this case the Mailbox PRIO field is included at the very left of the arbitration value (see the table below).

**Table 43-14. Composition of the arbitration value when Local Priority is enabled**

Format	Mailbox Arbitration Value (35 bits)					
Standard (IDE = 0)	PRIO (3 bits)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	- (18 bits)	- (1 bit)
Extended (IDE = 1)	PRIO (3 bits)	Extended ID[28:18 ](11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0 ] (18 bits)	RTR (1 bit)

As the PRIO field is the most significant part of the arbitration value Mailboxes with low PRIO values have higher priority than Mailboxes with high PRIO values regardless the rest of their arbitration values.

Note that the PRIO field is not part of the frame on the CAN bus. Its purpose is only to affect the internal arbitration process.

Once the arbitration winner is found, its content is copied to a hidden auxiliary MB called Tx Serial Message Buffer (Tx SMB), which has the same structure as a normal MB but is not user accessible. This operation is called "move-out" and after it is done, write access to the corresponding MB is blocked (if the AEN bit in MCR is asserted). The write access is released in the following events:

- After the MB is transmitted
- FlexCAN enters in Freeze Mode or Bus Off
- FlexCAN loses the bus arbitration or there is an error during the transmission

At the first opportunity window on the CAN bus, the message on the Tx SMB is transmitted according to the CAN protocol rules. FlexCAN transmits up to eight data bytes, even if the DLC (Data Length Code) field value is greater than that.

Arbitration process can be triggered in the following situations:

- During Rx and Tx frames from CAN CRC field to end of frame. Arbitration start point depends on instantiation parameters NUMBER\_OF\_MB and T ASD. Additionally, T ASD value may be changed (see [Control 2 Register \(FLEXCAN\\_CTRL2\)](#)) to optimize the arbitration start point.
- During CAN Bus Off state from TX\_ERR\_CNT=124 to 128. Arbitration start point depends on instantiation parameters NUMBER\_OF\_MB and T ASD. Additionally, T ASD value may be changed(see [Control 2 Register \(FLEXCAN\\_CTRL2\)](#)) to optimize the arbitration start point.
- During C/S write by CPU in Bus Idle. First C/S write starts arbitration process and a second C/S write during this same arbitration restarts the process. If other C/S writes are performed, Tx arbitration process is pending. If there is no arbitration winner after arbitration process has finished, then TX arbitration machine begins a new arbitration process.
- Arbitration winner deactivation during a valid arbitration window.
- Upon Leave Freeze Mode. If there is a re-synchronization during WaitForBusIdle arbitration process is restarted.

Arbitration process stops in the following situation:

- All Mailboxes were scanned.
- A Tx active Mailbox is found in case of Lowest Buffer feature enabled.
- Arbitration winner inactivation or abort during any arbitration process.

## Functional Description

- There was not enough time to finish Tx arbitration process. For instance, a deactivation was performed near the end of frame). In this case arbitration process is pending.
- Error or Overload flag in the bus.
- Low Power or Freeze Mode request in Idle state

Arbitration is considered pending as described below:

- It was not possible to finish arbitration process in time.
- C/S write during arbitration if write is performed in a MB which number is lower than the Tx arbitration pointer.
- Any C/S write if there is no Tx Arbitration process in progress.
- Rx Match has just updated a Rx Code to Tx Code.
- Entering Bus off state.

C/S write during arbitration has the following effect:

- If C/S write is performed in the arbitration winner, a new process is restarted immediately.
- C/S write during arbitration if write is performed in a MB which number is higher than the Tx arbitration pointer.

### 43.7.4 Receive Process

To be able to receive CAN frames into a Mailbox, the CPU must prepare it for reception by executing the steps listed here.

1. If the Mailbox is active (either Tx or Rx) inactivate the Mailbox (see [Message Buffer Inactivation](#)), preferably with a *safe inactivation* (see [Transmission Abort Mechanism](#));
2. Write the ID word;
3. Write the EMPTY code (0b0100) to the CODE field of the Control and Status word to activate the Mailbox.

Once the Mailbox is activated in the third step, it will be able to receive frames that match the programmed filter. At the end of a successful reception, the Mailbox is updated by the *move-in process* (see [Move-in](#)) as follows:

1. The received Data field (8 bytes at most) is stored;
2. The received Identifier field is stored;
3. The value of the Free Running Timer at the time of the second bit of frame's Identifier field is written into the Mailbox Time Stamp field;
4. The received SRR, IDE, RTR and DLC fields are stored;

5. The CODE field in the Control and Status word is updated. (see [Table 43-5](#) and [Table 43-6](#) in Section [Message Buffer Structure](#))
6. A status flag is set in the Interrupt Flag Register and an interrupt is generated if allowed by the corresponding Interrupt Mask Register bit.

The recommended way for the CPU servicing (read) the frame received in a Mailbox is using the following procedure:

1. Read the Control and Status word of that Mailbox;
2. Check if the BUSY bit is deasserted, indicating that the Mailbox is locked. Repeat step 1) while it is asserted. See [Message Buffer Lock Mechanism](#);
3. Read the contents of the Mailbox. Once Mailbox is locked now, its contents won't be modified by FlexCAN Move-in processes. See [Move-in](#);
4. Acknowledge the proper flag at IFLAG registers;
5. Read the Free Running Timer. It is optional but recommended to unlock Mailbox as soon as possible and make it available for reception.

The CPU should synchronize to frame reception by the status flag bit for the specific Mailbox in one of the IFLAG Registers and not by the CODE field of that Mailbox. Polling the CODE field does not work because once a frame was received and the CPU services the Mailbox (by reading the C/S word followed by unlocking the Mailbox), the CODE field will not return to EMPTY. It will remain FULL. If the CPU tries to workaround this behavior by writing to the C/S word to force an EMPTY code after reading the Mailbox without a prior *safe inactivation*, a newly received message matching the filter of that Mailbox may be lost.

In summary: never do polling by reading directly the C/S word of the Mailboxes. Instead, read the IFLAG registers.

Note that the received frame's Identifier field is always stored in the matching Mailbox, thus the contents of the ID field in a Mailbox may change if the match was due to masking. Note also that FlexCAN does receive frames transmitted by itself if there exists a matching Rx Mailbox, provided the MCR[SRX\_DIS] bit is not asserted. If MCR[SRX\_DIS] bit is asserted, FlexCAN will not store messages transmitted by itself in any MB, even if it contains a matching MB, and no interrupt flag or interrupt signal will be generated due to the frame reception.

To be able to receive CAN messages through the Rx FIFO, the CPU must enable and configure the Rx FIFO during Freeze Mode(see [Rx FIFO](#)). Upon receiving the Frames Available in Rx FIFO interrupt(see [Interrupt Masks 1 Register \(FLEXCAN\\_IMASK1\)](#), bit IFLAG[BUF5I] - Frames available in Rx FIFO), the CPU should service the received frame using the following procedure:

1. Read the Control and Status word (optional - needed only if a mask was used for IDE and RTR bits);
2. Read the ID field (optional - needed only if a mask was used);
3. Read the Data field;
4. Read the RXFIR register (optional);
5. Clear the Frames Available in Rx FIFO interrupt by writing 1 to IFLAG[BUF5I] bit (mandatory - releases the MB and allows the CPU to read the next Rx FIFO entry)

### 43.7.5 Matching Process

The matching process scans the MB memory looking for Rx MBs programmed with the same ID as the one received from the CAN bus. If the FIFO is enabled, the priority of scanning can be selected between Mailboxes and FIFO filters. In any case, the matching starts from the lowest number Message Buffer toward the higher ones. If no match is found within the first structure then the other is scanned subsequently. In the event that the FIFO is full, the matching algorithm will always look for a matching MB outside the FIFO region.

As the frame is being received, it is stored in a hidden auxiliary MB called Rx Serial Message Buffer (Rx SMB).

The matching process start point depends on the following conditions:

- if the received frame is a remote frame, the start point is the CRC field of the frame;
- if the received frame is a data frame with DLC field equal to zero, the start point is the CRC field of the frame;
- if the received frame is a data frame with DLC field different than zero, the start point is the DATA field of the frame;

If a matching ID is found in the FIFO table or in one of the Mailboxes, the contents of the SMB will be transferred to the FIFO or to the matched Mailbox by the move-in process. If any CAN protocol error is detected then no match results will be transferred to the FIFO or to the matched Mailbox at the end of reception.

The matching process scans all matching elements of both Rx FIFO (if enabled) and active Rx Mailboxes (CODE is EMPTY, FULL, OVERRUN or RANSWER) in search of a successful comparison with the matching elements of the Rx SMB that is receiving the frame on the CAN bus. The SMB has the same structure of a Mailbox. The reception structures (Rx FIFO or Mailboxes) associated with the matching elements that had a successful comparison are the *matched structures*. The *matching winner* is selected at the end of the scan among those matched structures and depends on conditions described ahead. Refer to the following table for details.

**Table 43-15. Matching architecture**

Structure	SMB[RTR]	CTRL2[RRS]	CTRL2[EACEN]	MB[IDE]	MB[RTR]	MB[ID] <sup>1</sup>	MB[CODE]
Mailbox	0	-	0	cmp <sup>2</sup>	no_cmp <sup>3</sup>	cmp_msk <sup>4</sup>	EMPTY or FULL or OVERRUN
Mailbox	0	-	1	cmp_msk	cmp_msk	cmp_msk	EMPTY or FULL or OVERRUN
Mailbox	1	0	-	cmp	no_cmp	cmp	RANSWER
Mailbox	1	1	0	cmp	no_cmp	cmp_msk	EMPTY or FULL or OVERRUN
Mailbox	1	1	1	cmp_msk	cmp_msk	cmp_msk	EMPTY or FULL or OVERRUN
FIFO <sup>5</sup>	-	-	-	cmp_msk	cmp_msk	cmp_msk	-

1. For Mailbox structure, If SMB[IDE] is asserted, the ID is 29 bits (ID Standard + ID Extended). In case of SMB[IDE] to be negated, the ID is only 11 bits (ID Standard). Please, refer to [Message Buffer Structure](#) for ID details. For FIFO structure, the ID depends on IDAM. Please, refer to [Rx FIFO Structure](#) for IDAM details.
2. cmp: Compares the SMB contents with the MB contents regardless the masks.
3. no\_cmp: The SMB contents are not compared with the MB contents.
4. cmp\_msk: Compares the SMB contents with MB contents taking into account the masks.
5. SMB[IDE] and SMB[RTR] are not taken into account when IDAM is type C.

A reception structure is *free-to-receive* when any of the following conditions is satisfied:

- the CODE field of the Mailbox is EMPTY;
- the CODE field of the Mailbox is either FULL or OVERRUN and it has already been serviced (the C/S word was read by the Arm and unlocked as described in [Message Buffer Lock Mechanism](#));
- the CODE field of the Mailbox is either FULL or OVERRUN and an inactivation is performed. (see [Message Buffer Inactivation](#))
- the Rx FIFO is not full.

The scan order for Mailboxes and Rx FIFO is from the matching element with lowest number to the higher ones.

The matching winner search for Mailboxes is affected by the MCR[IRMQ] bit. If it is negated the matching winner is the first matched Mailbox regardless if it is free-to-receive or not . If it is asserted, the matching winner is selected according to the priority below:

1. the first free-to-receive matched Mailbox;
2. the last non free-to-receive matched Mailbox.

It is possible to select the priority of scan between Mailboxes and Rx FIFO by the CTRL2[MRP] bit.

If the selected priority is Rx FIFO first:

- if the Rx FIFO is a matched structure and is free-to-receive then the Rx FIFO is the matching winner regardless of the scan for Mailboxes;
- otherwise (the Rx FIFO is not a matched structure or is not free-to-receive), then the matching winner is searched among Mailboxes as described above.

If the selected priority is Mailboxes first:

- if a free-to-receive matched Mailbox is found, it is the matching winner regardless the scan for Rx FIFO;
- if no matched Mailbox is found, then the matching winner is searched in the scan for the Rx FIFO;
- if both conditions above are not satisfied and a non free-to-receive matched Mailbox is found then the matching winner determination is conditioned by the MCR[IRMQ] bit:
  - if MCR[IRMQ] bit is negated the matching winner is the first matched Mailbox;
  - if MCR[IRMQ] bit is asserted the matching winner is the Rx FIFO if it is a free-to-receive matched structure, otherwise the matching winner is the last non free-to-receive matched Mailbox.

Please, refer to the table below for a summary of matching possibilities.

If a non-safe Mailbox inactivation (see [Message Buffer Inactivation](#)) occurs during matching process and the Mailbox inactivated is the temporary matching winner then the temporary matching winner is invalidated. The matching elements scan is not stopped nor restarted, it continues normally. The consequence is that the current matching process works as if the matching elements compared before the inactivation did not exist, therefore a message may be lost.

Suppose, for example, that the FIFO is disabled, IRMQ is enabled and there are two MBs with the same ID, and FlexCAN starts receiving messages with that ID. Let us say that these MBs are the second and the fifth in the array. When the first message arrives, the matching algorithm will find the first match in MB number 2. The code of this MB is EMPTY, so the message is stored there. When the second message arrives, the matching algorithm will find MB number 2 again, but it is not "free-to-receive", so it will keep looking and find MB number 5 and store the message there. If yet another message with the same ID arrives, the matching algorithm finds out that there are no matching MBs that are "free-to-receive", so it decides to overwrite the last matched MB, which is number 5. In doing so, it sets the CODE field of the MB to indicate OVERRUN.

**Table 43-16. Matching Possibilities and Resulting Reception Structures**

RFEN	IRMQ	MRP	Matched in MB	Matched in FIFO	Reception Structure	Description
No FIFO, only MB, match is always MB first						
0	0	X <sup>1</sup>	None <sup>2</sup>	- <sup>3</sup>	None	Frame lost by no match
0	0	X	Free <sup>4</sup>	-	FirstMB	
0	1	X	None	-	None	Frame lost by no match
0	1	X	Free	-	FirstMB	
0	1	X	NotFree	-	LastMB	Overrun
FIFO enabled, no match in FIFO is as if FIFO does not exist						
1	0	X	None	None <sup>5</sup>	None	Frame lost by no match
1	0	X	Free	None	FirstMB	
1	1	X	None	None	None	Frame lost by no match
1	1	X	Free	None	FirstMB	
1	1	X	NotFree	None	LastMB	Overrun
FIFO enabled, Queue disabled						
1	0	0	X	NotFull <sup>6</sup>	FIFO	
1	0	0	None	Full <sup>7</sup>	None	Frame lost by FIFO full (FIFO Overflow)
1	0	0	Free	Full	FirstMB	
1	0	0	NotFree	Full	FirstMB	
1	0	1	None	NotFull	FIFO	
1	0	1	None	Full	None	Frame lost by FIFO full (FIFO Overflow)
1	0	1	Free	X	FirstMB	
1	0	1	NotFree	X	FirstMB	Overrun
FIFO enabled, Queue enabled						
1	1	0	X	NotFull	FIFO	
1	1	0	None	Full	None	Frame lost by FIFO full (FIFO Overflow)
1	1	0	Free	Full	FirstMB	
1	1	0	NotFree	Full	LastMB	Overrun
1	1	1	None	NotFull	FIFO	
1	1	1	Free	X	FirstMB	
1	1	1	NotFree	NotFull	FIFO	
1	1	1	NotFree	Full	LastMB	Overrun

1. It is a don't care condition.
2. Matched in MB "None" means that the frame has not matched any MB (free-to-receive or non-free-to-receive).
3. It is a forbidden condition.
4. Matched in MB "Free" means that the frame matched at least one MB free-to-receive regardless it has matched MBs non-free-to-receive.
5. Matched in FIFO "None" means that the frame has not matched any filter in FIFO. It is as if the FIFO didn't exist (CTRL2[RFEN]=0).
6. Matched in FIFO "NotFull" means that the frame has matched a FIFO filter and has empty slots to receive it.
7. Matched in FIFO "Full" means that the frame has matched a FIFO filter but couldn't store it because it has no empty slots to receive it.

The ability to match the same ID in more than one MB can be exploited to implement a reception queue (in addition to the full featured FIFO) to allow more time for Arm to service the MBs. By programming more than one MB with the same ID, received messages will be queued into the MBs. Arm can examine the Time Stamp field of the MBs to determine the order in which the messages arrived.

Matching to a range of IDs is possible by using ID Acceptance Masks. FlexCAN supports individual masking per MB. Please refer to [Rx Mailboxes Global Mask Register \(FLEXCAN\\_RXMGMASK\)](#). During the matching algorithm, if a mask bit is asserted, then the corresponding ID bit is compared. If the mask bit is negated, the corresponding ID bit is "don't care". Please note that the Individual Mask Registers are implemented in RAM, so they are not initialized out of reset. Also, they can only be programmed while the module is in Freeze Mode,, otherwise they are blocked by hardware.

FlexCAN also supports an alternate masking scheme with only four mask registers (RGXMASK, RX14MASK, RX15MASK and RXFGMASK) for backward compatibility. This alternate masking scheme is enabled when the IRMQ bit in the MCR Register is negated.

## 43.7.6 Move Process

There are two types of move process, namely move-in and move-out.

### 43.7.6.1 Move-in

The move-in process is the copy of a message received by an Rx SMB to a Rx Mailbox or FIFO that has matched it. If the move destination is the Rx FIFO, attributes of the message are also copied to the RXFIR FIFO. Each Rx SMB has its own move-in process, but only one is performed at a given time as described ahead. The move-in starts only when the message held by the Rx SMB has a corresponding matching winner (see [Matching Process](#)) and all of the following conditions are true:

- the CAN bus has reached or let past either:
  - the second bit of Intermission field next to the frame that carried the message that is in the Rx SMB;
  - the first bit of an overload frame next to the frame that carried the message that is in the Rx SMB;
- there is no ongoing matching process;

- the destination Mailbox is not locked by Arm;
- there is no ongoing move-in process from another Rx SMB. If more than one move-in processes are to be started at the same time both are performed and the newest substitutes the oldest.

The term *pending move-in* is used throughout the document and stands for a move-to-be that still does not satisfy all of the aforementioned conditions.

The move-in is cancelled and the Rx SMB is able to receive another message if any of the following conditions is satisfied:

- the destination Mailbox is inactivated after the CAN bus has reached the first bit of Intermission field next to the frame that carried the message and its matching process has finished;
- there is a previous pending move-in to the same destination Mailbox.
- the Rx SMB is receiving a frame transmitted by the FlexCAN itself and the self-reception is disabled;
- any CAN protocol error is detected.

Note that the pending move-in is not cancelled if the module enters in Freeze or Low Power Mode. It only stays on hold waiting for exiting Low Power Mode and to be unlocked. If an MB is unlocked during Freeze Mode, the move-in happens immediately.

The move-in process consists of the following steps:

1. if the message is destined to the Rx FIFO, push IDHIT into the RXFIR FIFO;
2. reads the words DATA0-3 and DATA4-7 from the Rx SMB;
3. writes it in the words DATA0-3 and DATA4-7 of the Rx Mailbox;
4. reads the words Control/Status and ID from the Rx SMB;
5. writes it in the words Control/Status and ID of the Rx Mailbox, updating the CODE field according to [Table 43-5](#).

The move-in process is not atomic, in such a way that it is immediately cancelled by the inactivation of the destination Mailbox (see [Message Buffer Inactivation](#)) and in this case the Mailbox may be left partially updated, thus incoherent. The exception is if the move-in destination is an Rx FIFO Message Buffer, then the process cannot be cancelled.

The BUSY Bit (least significant bit of the CODE field) of the destination Message Buffer is asserted while the move-in is being performed in such a way that Arm beware that the Message Buffer content is temporarily incoherent.

### 43.7.6.2 Move-out

The move-out process is the copy of the content from a Tx Mailbox to the Tx SMB when a message for transmission is available (see [Arbitration process](#)). The move-out occurs in the following conditions:

- the first bit of Intermission field;
- during Bus off field when TX Error Counter is in the 124 to 128 range;
- during BusIdle field;
- during Wait For Bus Idle field.

The move-out process is not atomic. Only Arm has priority to access the memory concurrently out of BusIdle state. In BusIdle, the move-out has the lowest priority to the concurrent memory accesses.

### 43.7.7 Data Coherence

In order to maintain data coherency and FlexCAN proper operation, the Arm must obey the rules described in the [Transmit Process](#) and [Receive Process](#).

Any form of Arm accessing an MB structure within FlexCAN other than those specified may cause FlexCAN to behave in an unpredictable way.

#### 43.7.7.1 Transmission Abort Mechanism

The abort mechanism provides a safe way to request the abortion of a pending transmission. A feedback mechanism is provided to inform Arm if the transmission was aborted or if the frame could not be aborted and was transmitted instead.

In order to abort a transmission, Arm must write a specific abort code (0b1001) to the CODE field of the Control and Status word. The active MBs configured as transmission must be aborted first and then they may be updated. If the abort code is written to a Mailbox that is currently being transmitted, or to a Mailbox that was already loaded into the SMB for transmission, the write operation is blocked and the MB is kept active, but the abort request is captured and kept pending until one of the following conditions are satisfied:

- The module loses the bus arbitration
- There is an error during the transmission
- The module is put into Freeze Mode
- The module enters in BusOff state
- There is an overload frame

If none of conditions above are reached, the MB is transmitted correctly, the interrupt flag is set in the IFLAG register and an interrupt to the Arm is generated (if enabled). The abort request is automatically cleared when the interrupt flag is set. In the other hand, if one of the above conditions is reached, the frame is not transmitted, therefore the abort code is written into the CODE field, the interrupt flag is set in the IFLAG and an interrupt is (optionally) generated to Arm.

If Arm writes the ABORT code before the transmission begins internally, then the write operation is not blocked, therefore the MB is updated and the interrupt flag is set. In this way Arm just needs to read the abort code to make sure the active MB was *safely inactivated*. Although the AEN bit is asserted and Arm wrote the abort code, in this case the MB is inactivated and not aborted, because the transmission did not start yet. One Mailbox is only aborted when the abort request is captured and kept pending until one of the previous conditions are satisfied.

The abort procedure can be summarized as follows:

1. Arm checks the corresponding IFLAG and clears it, if asserted.
2. Arm writes 0b1001 into the CODE field of the C/S word.
3. Arm waits for the corresponding IFLAG indicating that the frame was either transmitted or aborted.
4. Arm reads the CODE field to check if the frame was either transmitted (CODE=0b1000) or aborted (CODE=0b1001).
5. It is necessary to clear the corresponding IFLAG in order to allow the MB to be reconfigured.

### 43.7.7.2 Message Buffer Inactivation

Inactivation is a mechanism provided to protect the Mailbox against updates by the FlexCAN internal processes, thus allowing Arm to rely on Mailbox data coherence after having updated it, even in Normal Mode.

If a Mailbox is inactivated it does not participate neither in the arbitration nor in the matching process until it is reactivated. See [Transmit Process](#) and [Receive Process](#) for more detailed instruction on how to inactivate and reactivate a Mailbox.

In order to inactivate a Mailbox Arm must update its CODE field to INACTIVE (either 0b0000 or 0b1000).

As the user is not able to synchronize the CODE field update with the FlexCAN internal processes an inactivation can lead to undesirable results:

## Functional Description

- a frame in the bus that matches the filtering of the inactivated Rx Mailbox may be lost without notice, even if there are other Mailboxes with the same filter;
- a frame containing the message within the inactivated Tx Mailbox may be transmitted without notice.

In order to eliminate such risk and perform a *safe inactivation* Arm must use the following mechanism along with the inactivation itself:

- for Tx Mailboxes, the Transmission Abort (see [Transmission Abort Mechanism](#));

The inactivation automatically unlocks the Mailbox (see [Message Buffer Lock Mechanism](#)).

Message Buffers that are part of the Rx FIFO cannot be inactivated. There is no write protection on FIFO region by FlexCAN. Arm must keep the data coherence into FIFO region when RFEN is asserted.

### 43.7.7.3 Message Buffer Lock Mechanism

Besides MB inactivation, FlexCAN has another data coherence mechanism for the receive process. When Arm reads the Control and Status word of an Rx MB with codes FULL or OVERRUN, FlexCAN assumes that Arm wants to read the whole MB in an atomic operation, and thus it sets an internal lock flag for that MB. The lock is released when Arm reads the Free Running Timer (global unlock operation), or when it reads the Control and Status word of another MB regardless of its code or when Arm writes into C/S word from locked MB. The MB locking is done to prevent a new frame to be written into the MB while Arm is reading it.

The locking mechanism only applies to Rx MBs that are not part of FIFO and have a code different than INACTIVE (0b0000) or EMPTY<sup>1</sup> (0b0100). Also, Tx MBs can not be locked.

Suppose, for example, that the FIFO is disabled and the second and the fifth MBs of the array are programmed with the same ID, and FlexCAN has already received and stored messages into these two MBs. Suppose now that the Arm decides to read MB number 5 and at the same time another message with the same ID is arriving. When Arm reads the Control and Status word of MB number 5, this MB is locked. The new message arrives and the matching algorithm finds out that there are no "free-to-receive" MBs, so it decides to override MB number 5. However, this MB is locked, so the new message can not be written there. It will remain in the SMB waiting for the MB to be unlocked, and only then will be written to the MB. If the MB is not unlocked in time and yet another

---

1. In previous FlexCAN versions, reading the C/S word locks the MB even if it is EMPTY. This behavior is maintained when the IRMQ bit is negated.

new message with the same ID arrives, then the new message overwrites the one on the SMB and there will be no indication of lost messages either in the CODE field of the MB or in the Error and Status Register.

While the message is being moved-in from the SMB to the MB, the BUSY bit on the CODE field is asserted. If Arm reads the Control and Status word and finds out that the BUSY bit is set, it should defer accessing the MB until the BUSY bit is negated.

If the BUSY bit is asserted or if the MB is empty, then reading the Control and Status word does not lock the MB.

Inactivation takes precedence over locking. If Arm inactivates a locked Rx Mailbox, then its lock status is negated and the Mailbox is marked as invalid for the current matching round. Any pending message on the SMB will not be transferred anymore to the Mailbox. An MB is unlocked when Arm reads the Free Running Timer Register (see [Free Running Timer Register \(FLEXCAN\\_TIMER\)](#)), or the C/S word of another MB.

Lock and unlock mechanisms have the same functionality in both Normal and Freeze modes.

An unlock during Normal or Freeze mode results in the move-in of the pending message. However, the move-in is postponed if an unlock occurs during any of the low power modes (see in [Modes of Operation](#) specific information on Module Disable or Stop modes) and it will take place only when the module resumes to Normal or Freeze modes.

### 43.7.8 Rx FIFO

The receive-only FIFO is enabled by asserting the RFEN bit in the MCR.

The reset value of this bit is zero to maintain software backward compatibility with previous versions of the module that did not have the FIFO feature. The FIFO is 6-message deep, therefore when the FIFO is enabled, the memory region occupied by the first 6 Message Buffers is reserved for use of the FIFO engine (see [Rx FIFO Structure](#)). Arm can read the received messages sequentially, in the order they were received, by repeatedly reading a Message Buffer structure at the output of the FIFO.

The IFLAG[BUF5I] (Frames available in Rx FIFO) is asserted when there is at least one frame available to be read from the FIFO. An interrupt is generated if it is enabled by the corresponding mask bit. Upon receiving the interrupt, Arm can read the message (accessing the output of the FIFO as a Message Buffer) and the RXFIR register and then clear the interrupt. If there are more messages in the FIFO the act of clearing the interrupt updates the output of the FIFO with the next message and update the RXFIR with the attributes of that message, reissuing the interrupt to Arm. Otherwise, the flag remains negated. The output of the FIFO is only valid when the IFLAG[BUF5I] is asserted.

The IFLAG[BUF6I] (Rx FIFO Warning) is asserted when the number of unread messages within the Rx FIFO is increased to 5 from 4 due to the reception of a new one, meaning that the Rx FIFO is almost full. The flag remains asserted until Arm clears it.

The IFLAG[BUF7I] (Rx FIFO Overflow) is asserted when an incoming message was lost because the Rx FIFO is full. Note that the flag will not be asserted when the Rx FIFO is full and the message was captured by a Mailbox. The flag remains asserted until the Arm clears it.

Clearing one of those three flags does not affect the state of the other two.

An interrupt is generated if an IFLAG bit is asserted and the corresponding mask bit is asserted too.

A powerful filtering scheme is provided to accept only frames intended for the target application, thus reducing the interrupt servicing work load. The filtering criteria is specified by programming a table of up to 128 32-bit registers, according to CTRL2[RFFN] setting, that can be configured to one of the following formats (see also [Rx FIFO Structure](#)):

- Format A: 128 IDAFs (extended or standard IDs including IDE and RTR)
- Format B: 256 IDAFs (standard IDs or extended 14-bit ID slices including IDE and RTR)
- Format C: 512 IDAFs (standard or extended 8-bit ID slices)

Every frame available in the FIFO has a corresponding IDHIT (Identifier Acceptance Filter Hit Indicator) that can be read by accessing the RXFIR register. The RXFIR[IDHIT] field refers to the message at the output of the FIFO and is valid whilst the IFLAG[BUF5I] flag is asserted. The RXFIR register must be read only before clearing the flag, which guarantees that the information refers to the correct frame within the FIFO.

Up to thirty two elements of the ID Filter Table are individually affected by the Individual Mask Registers (RXIMR0 - RXIMR31), according to CTRL2[RFFN] setting (refer to [Control 2 Register \(FLEXCAN\\_CTRL2\)](#)), allowing very powerful filtering criteria to be defined. If the MCR[IRMQ] bit is negated (or if the RXIMR are not available for the particular MCU), then the FIFO ID Filter Table is affected by RXFGMASK.

### 43.7.9 CAN Protocol Related Features

### 43.7.9.1 Remote Frames

Remote frame is a special kind of frame. The user can program a mailbox to be a Remote Request Frame by writing the mailbox as Transmit with the RTR bit set to '1'. After the remote request frame is transmitted successfully, the mailbox becomes a Receive Message Buffer, with the same ID as before.

When a remote request frame is received by FlexCAN, it can be treated in three ways, depending on Remote Request Storing (CTRL2[RRS]) and Rx FIFO Enable (MCR[RFEN]) bits:

- If RRS is negated the frame's ID is compared to the IDs of the Transmit Message Buffers with the CODE field 0b1010. If there is a matching ID, then this mailbox frame will be transmitted. Note that if the matching mailbox has the RTR bit set, then FlexCAN will transmit a remote frame as a response. The received remote request frame is not stored in a receive buffer. It is only used to trigger a transmission of a frame in response. The mask registers are not used in remote frame matching, and all ID bits (except RTR) of the incoming received frame should match. In the case that a remote request frame was received and matched a mailbox, this message buffer immediately enters the internal arbitration process, but is considered as normal Tx mailbox, with no higher priority. The data length of this frame is independent of the DLC field in the remote frame that initiated its transmission.
- If RRS is asserted the frame's ID is compared to the IDs of the receive mailboxes with the CODE field 0b0100, 0b0010 or 0b0110. If there is a matching ID, then this mailbox will store the remote frame in the same fashion of a data frame. No automatic remote response frame will be generated. The mask registers are used in the matching process.
- If RFEN is asserted FlexCAN will not generate an automatic response for remote request frames that match the FIFO filtering criteria. If the remote frame matches one of the target IDs, it will be stored in the FIFO and presented to the Arm. Note that for filtering formats A and B, it is possible to select whether remote frames are accepted or not. For format C, remote frames are always accepted (if they match the ID). Remote Request Frames are considered as normal frames, and generate a FIFO overflow when a successful reception occurs and the FIFO is already full.

### 43.7.9.2 Overload Frames

FLEXCAN does transmit overload frames due to detection of following conditions on CAN bus:

- Detection of a dominant bit in the first/second bit of Intermission

## Functional Description

- Detection of a dominant bit at the 7th bit (last) of End of Frame field (Rx frames)
- Detection of a dominant bit at the 8th bit (last) of Error Frame Delimiter or Overload Frame Delimiter

### 43.7.9.3 Time Stamp

The value of the Free Running Timer is sampled at the beginning of the Identifier field on the CAN bus, and is stored at the end of "move-in" in the TIME STAMP field, providing network behavior with respect to time.

Note that the Free Running Timer can be reset upon a specific frame reception, enabling network time synchronization. Refer to TSYN description in [Control 1 Register \(FLEXCAN\\_CTRL1\)](#).

### 43.7.9.4 Protocol Timing

The FLEXCAN module supports a variety of means to setup bit timing parameters that are required by the CAN protocol. The Control Register has various fields used to control bit timing parameters: PRES DIV, PROPSEG, PSEG1, PSEG2 and RJW. See [Control 1 Register \(FLEXCAN\\_CTRL1\)](#).

The PRES DIV field controls a prescaler that generates the Serial Clock (Sclock), whose period defines the 'time quantum' used to compose the CAN waveform. A time quantum is the atomic unit of time handled by the CAN engine.

$$f_{Tq} = \frac{f_{CANCLK}}{(\text{Prescaler value})}$$

A bit time is subdivided into three segments<sup>2</sup> (reference [Table 43-17](#)):

---

2. For further explanation of the underlying concepts please refer to ISO/DIS 11519-1, Section 10.3. Reference also the Bosch CAN 2.0A/B protocol specification dated September 1991 for bit timing.

- SYNC\_SEG: This segment has a fixed length of one time quantum. Signal edges are expected to happen within this section.
- Time Segment 1: This segment includes the Propagation Segment and the Phase Segment 1 of the CAN standard. It can be programmed by setting the PROPSEG and the PSEG1 fields of the CTRL Register so that their sum (plus 2) is in the range of 4 to 16 time quanta.
- Time Segment 2: This segment represents the Phase Segment 2 of the CAN standard. It can be programmed by setting the PSEG2 field of the CTRL Register (plus 1) to be 2 to 8 time quanta long.

$$\text{Bit Rate} = \frac{f_{Tq}}{\text{(number of Time Quanta)}}$$

**Figure 43-2. Segments within the Bit Time**

Whenever CAN bit is used as a measure of duration (e.g. MCR[FRZ\_ACK] and MCR[LPM\_ACK] in [Module Configuration Register \(FLEXCAN\\_MCR\)](#)), the number of peripheral clocks in one CAN bit can be calculated as:

$$\text{NCCP} = \frac{f_{\text{sys}} \times [1 + (\text{PSEG1} + 1) + (\text{PSEG2} + 1) + (\text{PROPSEG} + 1)] \times (\text{PRES DIV} + 1)}{f_{\text{CANCLK}}}$$

where:

## Functional Description

NCCP is the number of peripheral clocks in one CAN bit;

$f_{\text{CANCLK}}$  is the Protocol Engine (PE) Clock in Hz;

$f_{\text{SYS}}$  is the frequency of operation of the system (CHI) clock, in Hz;

PSEG1 is the value in CTRL1[PSEG1] field;

PSEG2 is the value in CTRL1[PSEG2] field;

PROPSEG is the value in CTRL1[PROPSEG] field;

PRES DIV is the value in CTRL1[PRES DIV] field.

For example, 180 CAN bits = 180 x NCCP peripheral clock periods.

Figure 43-2 gives an overview of the CAN compliant segment settings and the related parameter values.

**Table 43-17. Time Segment Syntax**

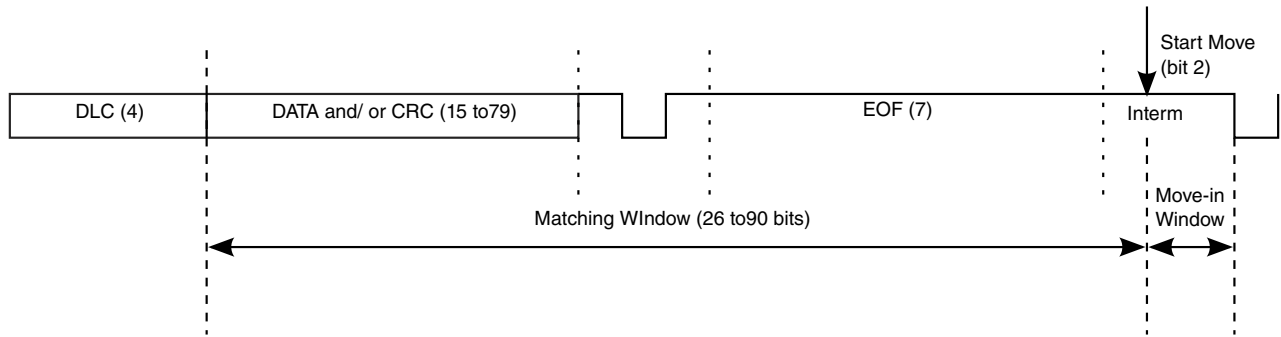

Syntax	Description
SYNC_SEG	System expects transitions to occur on the bus during this period.
Transmit Point	A node in transmit mode transfers a new value to the CAN bus at this point.
Sample Point	A node samples the bus at this point. If the three samples per bit option is selected, then this point marks the position of the third sample.

**Table 43-18. CAN Standard Compliant Bit Time Segment Settings**

Time Segment 1	Time Segment 2	Re-synchronization Jump Width
5 .. 10	2	1 .. 2
4 .. 11	3	1 .. 3
5 .. 12	4	1 .. 4
6 .. 13	5	1 .. 4
7 .. 14	6	1 .. 4
8 .. 15	7	1 .. 4
9 .. 16	8	1 .. 4

### 43.7.9.5 Arbitration and Matching Timing

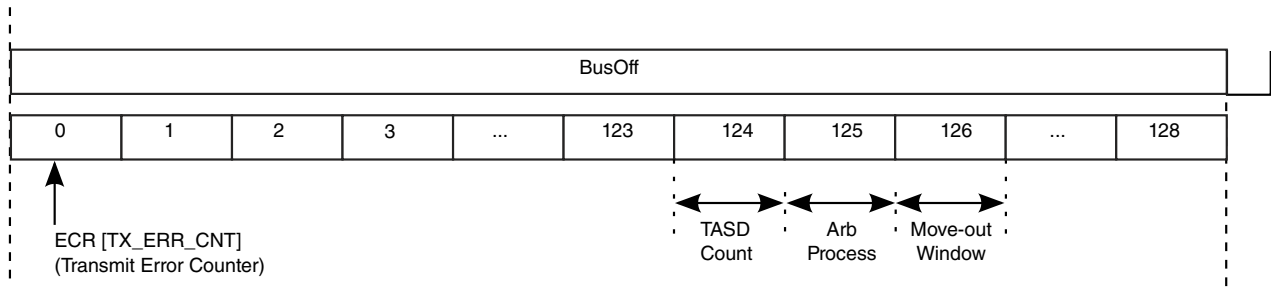

During normal reception and transmission of frames, the matching, arbitration, move-in and move-out processes are executed during certain time windows inside the CAN frame, as shown in the following figures.

**Figure 43-3. Matching and Move-In Time Windows**

**Figure 43-4. Arbitration and Move-Out Time Windows**

**Figure 43-5. Arbitration at the end of Bus Off and Move-Out Time Windows**

When doing matching and arbitration, FlexCAN needs to scan the whole Message Buffer memory during the available time window. In order to have sufficient time to do that, the following requirements must be observed:

- A valid CAN bit timing must be programmed, as indicated in [Table 43-18](#)
- The peripheral clock frequency can not be smaller than the oscillator clock frequency, i.e. the PLL can not be programmed to divide down the oscillator clock
- There must be a minimum ratio between the peripheral clock frequency and the CAN bit rate, as specified in the following table.

**Table 43-19. Minimum Ratio Between Peripheral Clock Frequency and CAN Bit Rate**

Number of Message Buffers	RFEN	Minimum Number of Peripheral Clocks per CAN bit
16 and 32	0	16
64	0	25
16	1	16
32	1	17
64	1	30

A direct consequence of the first requirement is that the minimum number of time quanta per CAN bit must be 8, so the oscillator clock frequency should be at least 8 times the CAN bit rate. The minimum frequency ratio specified in [Table 43-19](#) can be achieved by choosing a high enough peripheral clock frequency when compared to the oscillator clock frequency, or by adjusting one or more of the bit timing parameters (PRES DIV, PROPSEG, PSEG1, PSEG2). As an example, taking the case of 64 MBs, if the oscillator and peripheral clock frequencies are equal and the CAN bit timing is programmed to have 8 time quanta per bit, then the prescaler factor (PRES DIV + 1) should be at least 2. For prescaler factor equal to one and CAN bit timing with 8 time quanta per bit, the ratio between peripheral and oscillator clock frequencies should be at least 2.

### 43.7.10 Modes of Operation Details

The FlexCAN module has four functional modes (Normal Mode, Freeze Mode, Listen-Only Mode and Loop-Back Mode) and two low power modes (Disable Mode and Stop Mode). See in [Modes of Operation](#) an introductory description of all these modes of operation. The following sub-sections bring functional details on Freeze mode and the low power modes.

#### 43.7.10.1 Freeze Mode

This mode is requested by Arm through the assertion of the HALT bit in the MCR Register or when the MCU is put into Debug Mode. In both cases it is also necessary that the FRZ bit is asserted in the MCR Register and the module is not in any of the low power modes (Disable, Stop). The acknowledgement is obtained through the assertion by the FlexCAN of FRZ\_ACK bit in the same register. The Arm must only consider the FlexCAN in Freeze Mode when both request and acknowledgement conditions are satisfied.

When Freeze Mode is requested during transmission or reception, FlexCAN does the following:

- Waits to be in either Intermission, Passive Error, Bus Off or Idle state
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish. Pending move-in is not taken in account
- Ignores the FLEXCAN\_RX input pin and drives the FLEXCAN\_TX pin as recessive
- Stops the prescaler, thus halting all CAN protocol activities
- Grants write access to the Error Counters Register, which is read-only in other modes
- Sets the NOT\_RDY and FRZ\_ACK bits in MCR

After requesting Freeze Mode, the user must wait for the FRZ\_ACK bit to be asserted in MCR before executing any other action, otherwise FlexCAN may operate in an unpredictable way. In Freeze mode, all memory mapped registers are accessible, except for CTRL1[CLK\_SRC] bit that can be read but cannot be written.

Exiting Freeze Mode is done in one of the following ways:

- Arm negates the FRZ bit in the MCR Register
- The Arm is removed from Debug Mode and the HALT bit is negated

The FRZ\_ACK bit is negated after protocol engine recognizes the negation of freeze request. Once out of Freeze Mode, FlexCAN tries to re-synchronize to the CAN bus by waiting for 11 consecutive recessive bits.

### 43.7.10.2 Module Disable Mode

This low power mode is normally used to temporarily disable a complete FlexCAN block, with no power consumption. It is requested by the Arm through the assertion of the MDIS bit in the MCR Register and the acknowledgement is obtained through the assertion by the FlexCAN of the LPM\_ACK bit in the same register. The Arm must only consider the FlexCAN in Disable Mode when both request and acknowledgement conditions are satisfied.

If the module is disabled during Freeze Mode, it requests to disable the clocks to the PE and CHI sub-modules, sets the LPM\_ACK bit and negates the FRZ\_ACK bit. The ability to shut down the clocks depends on how FlexCAN is integrated into the MCU. If the module is disabled during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and then checks it to be recessive
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish. Pending move-in is not taken in account
- Ignores its FLEXCAN\_RX input pin and drives its FLEXCAN\_TX pin as recessive

- May shut down the clocks to the PE and CHI sub-modules, depending on how FlexCAN is integrated into the MCU
- Sets the NOT\_RDY and LPM\_ACK bits in MCR

The Bus Interface Unit continues to operate, enabling the Arm to access memory mapped registers, except the Rx Mailboxes Global Mask Registers, the Rx Buffer 14 Mask Register, the Rx Buffer 15 Mask Register, the Rx FIFO Global Mask Register. The Rx FIFO Information Register, the Message Buffers, the Rx Individual Mask Registers, and the reserved words within RAM may not be accessed when the module is in Disable Mode depending on how FlexCAN RAM is integrated into the Arm. Exiting from this mode is done by negating the MDIS bit by Arm, which make FlexCAN requests to resume the clocks and negates the LPM\_ACK bit after CAN protocol engine recognizes the negation of disable mode requested by Arm.

### 43.7.10.3 Stop Mode

This is a system low power mode in which system clocks can be stopped for maximum power savings. To enter stop mode, the CPU should manually assert a global Stop Mode request (see the CAN1\_STOP\_REQ and CAN2\_STOP\_REQ bit in the register IOMUXC\_GPR4) and check the acknowledgement asserted by the FlexCAN (see the CAN1\_STOP\_ACK and CAN2\_STOP\_ACK in the register IOMUXC\_GPR4). The CPU must only consider the FlexCAN in Stop Mode when both request and acknowledgement conditions are satisfied.

If FlexCAN receives the global Stop Mode request during Freeze Mode, it sets the LPM\_ACK bit, negates the FRZ\_ACK bit and then sends the Stop Acknowledge signal to the CPU, in order to shut down the clocks globally. If Stop Mode is requested during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and checks it to be recessive
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish. Pending move-in is not taken in account
- Ignores its FLEXCAN\_RX input pin and drives its FLEXCAN\_TX pin as recessive
- Sets the NOT\_RDY and LPM\_ACK bits in MCR
- Sends a Stop Acknowledge signal to the CPU, so that it can shut down the clocks globally

Exiting Stop Mode is done in one of the following ways:

- Arm resuming the clocks and removing the Stop Mode request
- Arm resuming the clocks and Stop Mode request as a result of the Self Wake mechanism

In the Self Wake mechanism, if the SLF\_WAK bit in MCR Register was set at the time FlexCAN entered Stop Mode, then upon detection of a recessive to dominant transition on the CAN bus, FlexCAN sets the WAK\_INT bit in the ESR Register and, if enabled by the WAK\_MSK bit in MCR, generates a Wake Up interrupt to the Arm. Upon receiving the interrupt, the Arm should resume the clocks and remove the Stop Mode request manually. FlexCAN will then wait for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, it will not receive the frame that woke it up .

The sensitivity to CAN bus activity can be modified by applying a low-pass filter function to the FLEXCAN\_RX input line while in Stop Mode. See the WAK\_SRC bit in [Module Configuration Register \(FLEXCAN\\_MCR\)](#) . This feature can be used to protect FlexCAN from waking up due to short glitches on the CAN bus lines. Such glitches can result from electromagnetic interference within noisy environments, the glitch filter width can be set in [Glitch Filter Width Register \(FLEXCAN\\_GFWR\)](#).

### 43.7.11 Interrupts

The module can generate up to 70 interrupt sources (64 interrupts due to message buffers and 6 interrupts due to Ored interrupts from MBs, Bus Off, Error, Tx Warning, Rx Warning and Wake Up)).

The number of actual sources depends on the configured number of message buffers.

Each one of the message buffers can be an interrupt source, if its corresponding IMASK bit is set. There is no distinction between Tx and Rx interrupts for a particular buffer, under the assumption that the buffer is initialized for either transmission or reception. Each of the buffers has assigned a flag bit in the IFLAG Registers. The bit is set when the corresponding buffer completes a successful transmission/reception and is cleared when the Arm writes it to '1' (unless another interrupt is generated at the same time).

If the Rx FIFO is enabled (bit RFEN on MCR set), the interrupts corresponding to MBs 0 to 7 have a different behavior. Bit 7 of the IFLAG1 becomes the "FIFO Overflow" flag; bit 6 becomes the FIFO Warning flag, bit 5 becomes the "Frames Available in FIFO flag" and bits 4-0 are unused. See [Interrupt Flags 1 Register \(FLEXCAN\\_IFLAG1\)](#) for more information.

A combined interrupt for all MBs is also generated by an Or of all the interrupt sources from MBs. This interrupt gets generated when any of the Mailboxes or FIFO generates an interrupt. The Arm must read the IFLAG Registers to determine which MB or FIFO caused the interrupt.

The other 5 interrupt sources (Bus Off, Error, Tx Warning, Rx Warning and Wake Up) generate interrupts like the MB ones, and can be read from both the Error and Status Register 1 and 2. The Bus Off, Error, Tx Warning and Rx Warning interrupt mask bits are located in the Control 1 Register and the Wake-Up interrupt mask bit is located in the MCR.

## **43.8 Initialization/Application Information**

This section provides instructions for initializing the FLEXCAN module.

### **43.8.1 FLEXCAN Initialization Sequence**

The FLEXCAN module may be reset in two ways:

- SOC level hard reset which resets all memory mapped registers asynchronously
- SOFT\_RST bit in MCR, which resets some of the memory mapped registers synchronously

Soft reset is synchronous and has to follow an internal request/acknowledge procedure across clock domains. Therefore, it may take some time to fully propagate its effects. The SOFT\_RST bit remains asserted while soft reset is pending, so software can poll this bit to know when the reset has completed. Also, soft reset can not be applied while clocks are shut down in any of the low power modes. The low power mode should be exited and the clocks resumed before applying soft reset.

After the module is enabled (MDIS bit negated), FLEXCAN automatically goes to Freeze Mode. In Freeze Mode, FLEXCAN is un-synchronized to the CAN bus, the HALT and FRZ bits in MCR Register are set, the internal state machines are disabled and the FRZ\_ACK and NOT\_RDY bits in the MCR Register are set. The FLEXCAN\_TX pin is in recessive state and FLEXCAN does not initiate any transmission or reception of CAN frames. Note that the Message Buffers and the Rx Individual Mask Registers are not affected by reset, so they are not automatically initialized.

For any configuration change/initialization it is required that FLEXCAN is put into Freeze Mode. The following is a generic initialization sequence applicable to the FLEXCAN module:

- Initialize the Module Configuration Register
  - Enable the individual filtering per MB and reception queue features by setting the IRMQ bit
  - Enable the warning interrupts by setting the WRN\_EN bit

- If required, disable frame self reception by setting the SRX\_DIS bit
- Enable the FIFO by setting the RFEN bit
- Enable the abort mechanism by setting the AEN bit
- Enable the local priority feature by setting the LPRIO\_EN bit
- Initialize the Control Register
  - Determine the bit timing parameters: PROPSEG, PSEG1, PSEG2, RJW
  - Determine the bit rate by programming the PRESDIV field
  - Determine the internal arbitration mode (LBUF bit)
- Initialize the Message Buffers
  - The Control and Status word of all Message Buffers must be initialized
  - If FIFO was enabled, the 8-entry ID table must be initialized
  - Other entries in each Message Buffer should be initialized as required
- Initialize the Rx Individual Mask Registers
- Set required interrupt mask bits in the IMASK Registers (for all MB interrupts), in CTRL Register (for Bus Off and Error interrupts) and in MCR Register for Wake-Up interrupt
- Negate the HALT bit in MCR

Starting with the last event, FLEXCAN attempts to synchronize to the CAN bus.

## 43.9 FLEXCAN Memory Map/Register Definition

The complete memory map for a FLEXCAN module with 64 MBs capability is shown in the following table. Each individual register is identified by its complete name and the corresponding mnemonic. The access type can be Supervisor (S) or Unrestricted (U). Most of the registers can be configured to have either Supervisor or Unrestricted access by programming the SUPV bit in the MCR Register. The MCR register allows only Supervisor access regardless the SUPV bit state.

The FLEXCAN module stores CAN messages for transmission and reception using a Mailboxes and Rx FIFO structure.

**FLEXCAN memory map**

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page

## FLEXCANx\_MCR field descriptions

Field	Description
31 MDIS	<p>This bit controls whether FLEXCAN is enabled or not. When disabled, FLEXCAN shuts down the clocks to the CAN Protocol Interface and Message Buffer Management sub-modules. This is the only bit in MCR not affected by soft reset. See <a href="#">Module Disable Mode</a> for more information.</p> <p>1 Disable the FLEXCAN module 0 Enable the FLEXCAN module</p>
30 FRZ	<p>The FRZ bit specifies the FLEXCAN behavior when the HALT bit in the MCR Register is set or when Debug Mode is requested at Arm level. When FRZ is asserted, FLEXCAN is enabled to enter Freeze Mode. Negation of this bit field causes FLEXCAN to exit from Freeze Mode.</p> <p>1 Enabled to enter Freeze Mode 0 Not enabled to enter Freeze Mode</p>
29 RFEN	<p>This bit controls whether the Rx FIFO feature is enabled or not. When RFEN is set, MBs 0 to 5 cannot be used for normal reception and transmission because the corresponding memory region (0x80-0xDC) is used by the FIFO engine as well as additional MBs (up to 32, depending on CTRL2[RFFN] setting) which are used as Rx FIFO ID Filter Table elements. RFEN also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in <a href="#">Table 43-19</a> (see <a href="#">Arbitration and Matching Timing</a>). This bit can only be written in Freeze mode as it is blocked by hardware in other modes.</p> <p>1 FIFO enabled 0 FIFO not enabled</p>
28 HALT	<p>Assertion of this bit puts the FLEXCAN module into Freeze Mode. The Arm should clear it after initializing the Message Buffers and Control Register. No reception or transmission is performed by FLEXCAN before this bit is cleared. Freeze Mode can not be entered while FLEXCAN is in any of the low power modes. See <a href="#">Freeze Mode</a> for more information.</p> <p>1 Enters Freeze Mode if the FRZ bit is asserted. 0 No Freeze Mode request.</p>
27 NOT_RDY	<p>This read-only bit indicates that FLEXCAN is either in Disable Mode, Stop Mode or Freeze Mode. It is negated once FLEXCAN has exited these modes.</p> <p>1 FLEXCAN module is either in Disable Mode, Stop Mode or Freeze Mode 0 FLEXCAN module is either in Normal Mode, Listen-Only Mode or Loop-Back Mode</p>
26 WAK_MSK	<p>This bit enables the Wake Up Interrupt generation.</p> <p>1 Wake Up Interrupt is enabled 0 Wake Up Interrupt is disabled</p>
25 SOFT_RST	<p>When this bit is asserted, FlexCAN resets its internal state machines and some of the memory mapped registers. The following registers are reset: MCR (except the MDIS bit), TIMER, ECR, ESR1, ESR2, IMASK1, IMASK2, IFLAG1, IFLAG2 and CRCR. Configuration registers that control the interface to the CAN bus are not affected by soft reset. The following registers are unaffected: CTRL1, CTRL2, RXIMR0_RXIMR63, RXGMASK, RX14MASK, RX15MASK, RXFGMASK, RXFIR and all Message Buffers</p> <p>The SOFT_RST bit can be asserted directly by the Arm when it writes to the MCR Register. It may take some time to fully propagate its effect. The SOFT_RST bit remains asserted while reset is pending, and is automatically negated when reset completes. Therefore, software can poll this bit to know when the soft reset has completed.</p> <p>Soft reset cannot be applied while clocks are shut down in any of the low power modes. The module should be first removed from low power mode, and then soft reset can be applied.</p>

*Table continues on the next page...*

## FLEXCANx\_MCR field descriptions (continued)

Field	Description
	1 Reset the registers 0 No reset request
24 FRZ_ACK	This read-only bit indicates that FLEXCAN is in Freeze Mode and its prescaler is stopped. The Freeze Mode request cannot be granted until current transmission or reception processes have finished. Therefore the software can poll the FRZ_ACK bit to know when FLEXCAN has actually entered Freeze Mode. If Freeze Mode request is negated, then this bit is negated once the FLEXCAN prescaler is running again. If Freeze Mode is requested while FLEXCAN is in any of the low power modes, then the FRZ_ACK bit will only be set when the low power mode is exited. See <a href="#">Freeze Mode</a> for more information  1 FLEXCAN in Freeze Mode, prescaler stopped 0 FLEXCAN not in Freeze Mode, prescaler running
23 SUPV	This bit configures some of the FLEXCAN registers to be either in Supervisor or User Mode. Reset value of this bit is '1', so the affected registers start with Supervisor access allowance only. This bit can only be written in Freeze mode as it is blocked by hardware in other modes.  1 FlexCAN is in Supervisor Mode. Affected registers allow only Supervisor access. Unrestricted access behaves as though the access was done to an unimplemented register location 0 FlexCAN is in User Mode. Affected registers allow both Supervisor and Unrestricted accesses
22 SLF_WAK	This bit enables the Self Wake Up feature when FLEXCAN is in Stop Mode. If this bit had been asserted by the time FLEXCAN entered Stop Mode, then FLEXCAN will look for a recessive to dominant transition on the bus during these modes. If a transition from recessive to dominant is detected during Stop Mode, then FLEXCAN generates, if enabled to do so, a Wake Up interrupt to the Arm so that it can resume the clocks globally and FlexCAN can request to resume the clocks. This bit can not be written while the module is in Stop Mode.  1 FLEXCAN Self Wake Up feature is enabled 0 FLEXCAN Self Wake Up feature is disabled
21 WRN_EN	When asserted, this bit enables the generation of the TWRN_INT and RWRN_INT flags in the Error and Status Register. If WRN_EN is negated, the TWRN_INT and RWRN_INT flags will always be zero, independent of the values of the error counters, and no warning interrupt will ever be generated. This bit can only be written in Freeze mode as it is blocked by hardware in other modes.  1 TWRN_INT and RWRN_INT bits are set when the respective error counter transition from <96 to ≥ 96. 0 TWRN_INT and RWRN_INT bits are zero, independent of the values in the error counters.
20 LPM_ACK	This read-only bit indicates that FLEXCAN is either in Disable Mode or Stop Mode. Either of these low power modes can not be entered until all current transmission or reception processes have finished, so the Arm can poll the LPM_ACK bit to know when FLEXCAN has actually entered low power mode. See <a href="#">Module Disable Mode</a> , and <a href="#">Stop Mode</a> for more information  1 FLEXCAN is either in Disable Mode, or Stop mode 0 FLEXCAN not in any of the low power modes
19 WAK_SRC	This bit defines whether the integrated low-pass filter is applied to protect the FLEXCAN_RX input from spurious wake up. See <a href="#">Stop Mode</a> for more information. This bit can only be written in Freeze mode as it is blocked by hardware in other modes.  1 FLEXCAN uses the filtered FLEXCAN_RX input to detect recessive to dominant edges on the CAN bus 0 FLEXCAN uses the unfiltered FLEXCAN_RX input to detect recessive to dominant edges on the CAN bus.
18 -	This field is reserved. Reserved

Table continues on the next page...

## FLEXCANx\_MCR field descriptions (continued)

Field	Description
17 SRX_DIS	<p>This bit defines whether FlexCAN is allowed to receive frames transmitted by itself. If this bit is asserted, frames transmitted by the module will not be stored in any MB, regardless if the MB is programmed with an ID that matches the transmitted frame, and no interrupt flag or interrupt signal will be generated due to the frame reception. This bit can only be written in Freeze mode as it is blocked by hardware in other modes.</p> <p>1 Self reception disabled 0 Self reception enabled</p>
16 IRMQ	<p>This bit indicates whether Rx matching process will be based either on individual masking and queue or on masking scheme with RXMGMASK, RX14MASK and RX15MASK, RXFGMASK. This bit can only be written in Freeze mode as it is blocked by hardware in other modes.</p> <p>1 Individual Rx masking and queue feature are enabled. 0 Individual Rx masking and queue feature are disabled. For backward compatibility, the reading of C/S word locks the MB even if it is EMPTY.</p>
15–14 -	<p>This field is reserved. Reserved</p>
13 LPRIO_EN	<p>This bit is provided for backwards compatibility reasons. It controls whether the local priority feature is enabled or not. It is used to extend the ID used during the arbitration process. With this extended ID concept, the arbitration process is done based on the full 32-bit word, but the actual transmitted ID still has 11-bit for standard frames and 29-bit for extended frames. This bit can only be written in Freeze mode as it is blocked by hardware in other modes.</p> <p>1 Local Priority enabled 0 Local Priority disabled</p>
12 AEN	<p>This bit is supplied for backwards compatibility reasons. When asserted, it enables the Tx abort feature. This feature guarantees a safe procedure for aborting a pending transmission, so that no frame is sent in the CAN bus without notification. This bit can only be written in Freeze mode as it is blocked by hardware in other modes. Write Abort code into Rx Mailboxes can cause unpredictable results when the MCR[AEN] is asserted.</p> <p>1 Abort enabled 0 Abort disabled</p>
11–10 -	<p>This field is reserved. Reserved</p>
9–8 IDAM	<p>This 2-bit field identifies the format of the elements of the Rx FIFO filter table, as shown below. Note that all elements of the table are configured at the same time by this field (they are all the same format). See <a href="#">Rx FIFO Structure</a>. This bit can only be written in Freeze mode as it is blocked by hardware in other modes.</p> <p>00 Format A One full ID (standard or extended) per ID filter Table element. 01 Format B Two full standard IDs or two partial 14-bit extended IDs per ID filter Table element. 10 Format C Four partial 8-bit IDs (standard or extended) per ID filter Table element. 11 Format D All frames rejected.</p>
7 -	<p>This field is reserved. Reserved</p>
MAXMB	<p>This 7-bit field defines the number of the last Message Buffers that will take part in the matching and arbitration processes. The reset value (0x0F) is equivalent to 16 MB configuration. This field can only be written in Freeze Mode as it is blocked by hardware in other modes</p> <p>Number of the last MB = MAXMB.</p>

*Table continues on the next page...*

**FLEXCANx\_MCR field descriptions (continued)**

Field	Description
	<b>NOTE:</b> Additionally, the value of MAXMB must encompass the FIFO size defined by CTRL2[RFFN] MAXMB also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in <a href="#">Table 43-19</a> (see <a href="#">Arbitration and Matching Timing</a> ).

**43.9.2 Control 1 Register (FLEXCANx\_CTRL1)**

This register is defined for specific FLEXCAN control features related to the CAN bus, such as bit-rate, programmable sampling point within an Rx bit, Loop Back Mode, Listen Only Mode, Bus Off recovery behavior and interrupt enabling (Bus-Off, Error, Warning). It also determines the Division Factor for the clock prescaler.

Address: Base address + 4h offset

**FLEXCANx\_CTRL1 field descriptions**

Field	Description
31-24 PRESDIV	This 8-bit field defines the ratio between the PE clock frequency and the Serial Clock (Sclock) frequency. The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency. The Maximum value of this register is 0xFF, that gives a minimum Sclock frequency equal to the PE clock frequency divided by 256. For more information refer to <a href="#">Protocol Timing</a> . This field can only be written in Freeze mode as it is blocked by hardware in other modes.

Table continues on the next page...

## FLEXCANx\_CTRL1 field descriptions (continued)

Field	Description
	Slock frequency = CPI clock frequency / (PRESDIV+1)
23–22 RJW	This 2-bit field defines the maximum number of time quanta <sup>1</sup> that a bit time can be changed by one re-synchronization. The valid programmable values are 0-3. This field can only be written in Freeze mode as it is blocked by hardware in other modes  Resync Jump Width = RJW + 1.
21–19 PSEG1	This 3-bit field defines the length of Phase Buffer Segment 1 in the bit time . The valid programmable values are 0-7. This field can only be written in Freeze mode as it is blocked by hardware in other modes  Phase Buffer Segment 1 = (PSEG1 + 1) x Time-Quanta.
18–16 PSEG2	This 3-bit field defines the length of Phase Buffer Segment 2 in the bit time . The valid programmable values are 1-7. This field can only be written in Freeze mode as it is blocked by hardware in other modes  Phase Buffer Segment 2 = (PSEG2 + 1) x Time-Quanta.
15 BOFF_MSK	This bit provides a mask for the Bus Off Interrupt.  1 Bus Off interrupt enabled 0 Bus Off interrupt disabled
14 ERR_MSK	This bit provides a mask for the Error Interrupt.  1 Error interrupt enabled 0 Error interrupt disabled
13 -	This field is reserved. Reserved
12 LPB	This bit configures FlexCAN to operate in Loop-Back Mode. In this mode, FlexCAN performs an internal loop back that can be used for self test operation. The bit stream output of the transmitter is fed back internally to the receiver input. The FLEXCAN_RX input pin is ignored and the FLEXCAN_TX output goes to the recessive state (logic '1'). FlexCAN behaves as it normally does when transmitting, and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field, generating an internal acknowledge bit to ensure proper reception of its own message. Both transmit and receive interrupts are generated. This bit can only be written in Freeze mode as it is blocked by hardware in other modes.  1 Loop Back enabled 0 Loop Back disabled
11 TWRN_MSK	This bit provides a mask for the Tx Warning Interrupt associated with the TWRN_INT flag in the Error and Status Register. This bit is read as zero when MCR[WRN_EN] bit is negated. This bit can only be written if MCR[WRN_EN] bit is asserted.  1 Tx Warning Interrupt enabled 0 Tx Warning Interrupt disabled
10 RWRN_MSK	This bit provides a mask for the Rx Warning Interrupt associated with the RWRN_INT flag in the Error and Status Register. This bit is read as zero when MCR[WRN_EN] bit is negated. This bit can only be written if MCR[WRN_EN] bit is asserted.  1 Rx Warning Interrupt enabled 0 Rx Warning Interrupt disabled
9–8 -	This field is reserved. Reserved
7 SMP	This bit defines the sampling mode of CAN bits at the FLEXCAN_RX. This bit can only be written in Freeze mode as it is blocked by hardware in other modes.

Table continues on the next page...

**FLEXCANx\_CTRL1 field descriptions (continued)**

Field	Description
	<p>1 Three samples are used to determine the value of the received bit: the regular one (sample point) and 2 preceding samples, a majority rule is used</p> <p>0 Just one sample is used to determine the bit value</p>
6 BOFF_REC	<p>This bit defines how FLEXCAN recovers from Bus Off state. If this bit is negated, automatic recovering from Bus Off state occurs according to the CAN Specification 2.0B. If the bit is asserted, automatic recovering from Bus Off is disabled and the module remains in Bus Off state until the bit is negated by the user. If the negation occurs before 128 sequences of 11 recessive bits are detected on the CAN bus, then Bus Off recovery happens as if the BOFF_REC bit had never been asserted. If the negation occurs after 128 sequences of 11 recessive bits occurred, then FLEXCAN will re-synchronize to the bus by waiting for 11 recessive bits before joining the bus. After negation, the BOFF_REC bit can be re-asserted again during Bus Off, but it will only be effective the next time the module enters Bus Off. If BOFF_REC was negated when the module entered Bus Off, asserting it during Bus Off will not be effective for the current Bus Off recovery.</p> <p>1 Automatic recovering from Bus Off state disabled</p> <p>0 Automatic recovering from Bus Off state enabled, according to CAN Spec 2.0 part B</p>
5 TSYN	<p>This bit enables a mechanism that resets the free-running timer each time a message is received in Message Buffer 0. This feature provides means to synchronize multiple FLEXCAN stations with a special "SYNC" message (i.e., global network time). If the RFEN bit in MCR is set (FIFO enabled), the first available Mailbox, according to CTRL2[RFFN] setting, is used for timer synchronization instead of MB0. This bit can only be written in Freeze mode as it is blocked by hardware in other modes.</p> <p>1 Timer Sync feature enabled</p> <p>0 Timer Sync feature disabled</p>
4 LBUF	<p>This bit defines the ordering mechanism for Message Buffer transmission. When asserted, the LPRIO_EN bit does not affect the priority arbitration. This bit can only be written in Freeze mode as it is blocked by hardware in other modes.</p> <p>1 Lowest number buffer is transmitted first</p> <p>0 Buffer with highest priority is transmitted first</p>
3 LOM	<p>This bit configures FLEXCAN to operate in Listen Only Mode. In this mode, transmission is disabled, all error counters are frozen and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station will be received. If FLEXCAN detects a message that has not been acknowledged, it will flag a BIT0 error (without changing the REC), as if it was trying to acknowledge the message.</p> <p>Listen-Only Mode acknowledgement can be obtained by the state of ESR1[FLT_CONF] field which is Passive Error when Listen-Only Mode is entered. There can be some delay between the Listen-Only Mode request and acknowledge.</p> <p>This bit can only be written in Freeze mode as it is blocked by hardware in other modes.</p> <p>1 FLEXCAN module operates in Listen Only Mode</p> <p>0 Listen Only Mode is deactivated</p>
PROP_SEG	<p>This 3-bit field defines the length of the Propagation Segment in the bit time. The valid programmable values are 0-7. This field can only be written in Freeze mode as it is blocked by hardware in other modes</p> <p>Propagation Segment Time = (PROPSEG + 1) * Time-Quanta.</p> <p>Time-Quantum = one Sclock period.</p>

1. One time quantum is equal to the Sclock period.

### 43.9.3 Free Running Timer Register (FLEXCANx\_TIMER)

This register represents a 16-bit free running counter that can be read and written by the Arm. The timer starts from \$0000 after Reset, counts linearly to \$FFFF, and wraps around.

The timer is clocked by the FLEXCAN bit-clock (which defines the baud rate on the CAN bus). During a message transmission/reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate. During Freeze Mode, disable, and stop mode, the timer is not incremented.

The timer value is captured at the beginning of the identifier field of any frame on the CAN bus. This captured value is written into the Time Stamp entry in a message buffer after a successful reception or transmission of a message.

If bit CTRL1[TSYN] is asserted the Timer is reset whenever a message is received in the first available Mailbox, according to CTRL2[RFFN] setting.

Arm can write to this register anytime. However, if the write occurs at the same time that the Timer is being reset by a reception in the first Mailbox, then the write value is discarded.

Reading this register affects the Mailbox Unlocking procedure. For additional details, refer to [Message Buffer Lock Mechanism](#).

Address: Base address + 8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Field	Description
31–16 -	This field is reserved. Reserved
TIMER	TIMER

### 43.9.4 Rx Mailboxes Global Mask Register (FLEXCANx\_RXMGMASK)

RXMGMASK is provided for legacy support. Asserting the MCR[IRMQ] bit causes the RXMGMASK Register to have no effect on the module operation.

RXMGMASK is used to mask the filter fields of all Rx MBs, excluding MBs 14-15, which have individual mask registers.

This register can only be written in Freeze mode as it is blocked by hardware in other modes.

**Table 43-20. Rx Mailboxes Global Mask usage**

SMB[RTR] <sup>1</sup>	CTRL2[RRS]	CTRL2[EACEN]	Mailbox filter fields			
			MB[RTR]	MB[IDE]	MB[ID]	reserved
0	-	0	- Note <sup>2</sup>	- Note <sup>3</sup>	MG[28:0]	MG[31:29]
0	-	1	MG[31]	MG[30]	MG[28:0]	MG[29]
1	0	-	-	-	-	MG[31:0]
1	1	0	-	-	MG[28:0]	MG[31:29]
1	1	1	MG[31]	MG[30]	MG[28:0]	MG[29]

1. RTR bit of the Incoming Frame. It is saved into an auxiliary MB called Rx Serial Message Buffer (Rx SMB).
2. If CTRL2[EACEN] bit is negated the RTR bit of Mailbox is never compared with the RTR bit of the Incoming Frame (Rx SMB[RTR]).
3. If CTRL2[EACEN] bit is negated the IDE bit of Mailbox is always compared with the IDE bit of the Incoming Frame (Rx SMB[IDE]).

Address: Base address + 10h offset

**FLEXCANx\_RXMGMASK field descriptions**

Field	Description
MG31_MG0	<p>These bits mask the Mailbox filter bits as shown in the figure above. Note that the alignment with the ID word of the Mailbox is not perfect as the two most significant MG bits affect the fields RTR and IDE which are located in the Control and Status word of the Mailbox. <a href="#">Rx Mailboxes Global Mask Register (FLEXCAN_RXMGMASK)</a> shows in detail which MG bits mask each Mailbox filter field.</p> <p>1 The corresponding bit in the filter is checked against the one received                      0 the corresponding bit in the filter is "don't care"</p>

**43.9.5 Rx Buffer 14 Mask Register (FLEXCANx\_RX14MASK)**

RX14MASK is provided for legacy support, asserting the MCR[IRMQ] bit causes the RX14MASK to have no effect on the module operation.

RX14MASK is used to mask the filter fields of Message Buffer 14.

This register can only be programmed while the module is in Freeze Mode as it is blocked by hardware in other modes.

Address: Base address + 14h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### FLEXCANx\_RX14MASK field descriptions

Field	Description
RX14M31_ RX14M0	<p>These bits mask Mailbox 14 filter bits in the same fashion as RXMGMASK masks other Mailboxes filters (see <a href="#">Rx Mailboxes Global Mask Register (FLEXCAN_RXMGMASK)</a>)</p> <p>1 The corresponding bit in the filter is checked 0 the corresponding bit in the filter is "don't care"</p>

## 43.9.6 Rx Buffer 15 Mask Register (FLEXCANx\_RX15MASK)

RX15MASK is provided for legacy support, asserting the MCR[IRMQ] bit causes the RX15MASK Register to have no effect on the module operation.

RX15MASK is used to mask the filter fields of Message Buffer 15.

This register can only be programmed while the module is in Freeze Mode as it is blocked by hardware in other modes.

Address: Base address + 18h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### FLEXCANx\_RX15MASK field descriptions

Field	Description
RX15M31_ RX15M0	<p>These bits mask Mailbox 15 filter bits in the same fashion as RXMGMASK masks other Mailboxes filters (see <a href="#">Rx Mailboxes Global Mask Register (FLEXCAN_RXMGMASK)</a>).</p> <p>1 The corresponding bit in the filter is checked 0 the corresponding bit in the filter is "don't care"</p>

### 43.9.7 Error Counter Register (FLEXCANx\_ECR)

This register has 2 8-bit fields reflecting the value of two FLEXCAN error counters: Transmit Error Counter (Tx\_Err\_Counter field) and Receive Error Counter (Rx\_Err\_Counter field). The rules for increasing and decreasing these counters are described in the CAN protocol and are completely implemented in the FLEXCAN module. Both counters are read only except in Freeze Mode, where they can be written by the Arm.

FLEXCAN responds to any bus state as described in the protocol, e.g. transmit 'Error Active' or 'Error Passive' flag, delay its transmission start time ('Error Passive') and avoid any influence on the bus when in 'Bus Off' state. The following are the basic rules for FLEXCAN bus state transitions.

- If the value of Tx\_Err\_Counter or Rx\_Err\_Counter increases to be greater than or equal to 128, the FLT\_CONF field in the Error and Status Register is updated to reflect 'Error Passive' state.
- If the FLEXCAN state is 'Error Passive', and either Tx\_Err\_Counter or Rx\_Err\_Counter decrements to a value less than or equal to 127 while the other already satisfies this condition, the FLT\_CONF field in the Error and Status Register is updated to reflect 'Error Active' state.
- If the value of Tx\_Err\_Counter increases to be greater than 255, the FLT\_CONF field in the Error and Status Register is updated to reflect 'Bus Off' state, and an interrupt may be issued. The value of Tx\_Err\_Counter is then reset to zero.
- If FLEXCAN is in 'Bus Off' state, then Tx\_Err\_Counter is cascaded together with another internal counter to count the 128th occurrences of 11 consecutive recessive bits on the bus. Hence, Tx\_Err\_Counter is reset to zero and counts in a manner where the internal counter counts 11 such bits and then wraps around while incrementing the Tx\_Err\_Counter. When Tx\_Err\_Counter reaches the value of 128, the FLT\_CONF field in the Error and Status Register is updated to be 'Error Active' and both error counters are reset to zero. At any instance of dominant bit following a stream of less than 11 consecutive recessive bits, the internal counter resets itself to zero without affecting the Tx\_Err\_Counter value.
- If during system start-up, only one node is operating, then its Tx\_Err\_Counter increases in each message it is trying to transmit, as a result of acknowledge errors (indicated by the ACK\_ERR bit in the Error and Status Register). After the transition to 'Error Passive' state, the Tx\_Err\_Counter does not increment anymore by acknowledge errors. Therefore the device never goes to the 'Bus Off' state.
- If the Rx\_Err\_Counter increases to a value greater than 127, it is not incremented further, even if more errors are detected while being a receiver. At the next

successful message reception, the counter is set to a value between 119 and 127 to resume to 'Error Active' state.

## 43.9.8 Error and Status 1 Register (FLEXCANx\_ESR1)

This register reflects various error conditions, some general status of the device and it is the source of four interrupts to the Arm.

The Arm read action clears bits 15-10, therefore the reported *error conditions*(bits 15-10) are those that occurred since the last time the Arm read this register. Bits 9-3 are status bits .

Some bits in this register are read-only and some are not .

**Table 43-21. FlexCAN State**

## FLEXCAN Memory Map/Register Definition

Address: Base address + 20h offset

### FLEXCANx\_ESR1 field descriptions

Field	Description
31–19 -	This field is reserved. Reserved
18 SYNCH	This read-only flag indicates whether the FlexCAN is synchronized to the CAN bus and able to participate in the communication process. It is set and cleared by the FlexCAN. Refer to <a href="#">Table 43-21</a>  1 FlexCAN is synchronized to the CAN bus 0 FlexCAN is not synchronized to the CAN bus
17 TWRN_INT	If the WRN_EN bit in MCR is asserted, the TWRN_INT bit is set when the TX_WRN flag transition from '0' to '1', meaning that the Tx error counter reached 96. If the corresponding mask bit in the Control Register (TWRN_MSK) is set, an interrupt is generated to the Arm. This bit is cleared by writing it to '1'. When WRN_EN is negated, this flag is masked. Arm must clear this flag before disabling the bit. Otherwise it will be set when the WRN_EN is set again. Writing '0' has no effect. This flag is not generated during "Bus Off" state. This bit is not updated during Freeze mode.  1 The Tx error counter transition from < 96 to >= 96 0 No such occurrence

Table continues on the next page...

## FLEXCANx\_ESR1 field descriptions (continued)

Field	Description
16 RWRN_INT	<p>If the WRN_EN bit in MCR is asserted, the RWRN_INT bit is set when the RX_WRN flag transition from '0' to '1', meaning that the Rx error counters reached 96. If the corresponding mask bit in the Control Register (RWRN_MSK) is set, an interrupt is generated to the Arm. This bit is cleared by writing it to '1'. When WRN_EN is negated, this flag is masked. Arm must clear this flag before disabling the bit. Otherwise it will be set when the WRN_EN is set again. Writing '0' has no effect. This bit is not updated during Freeze mode.</p> <p>1 The Rx error counter transition from &lt; 96 to &gt;= 96 0 No such occurrence</p>
15 BIT1_ERR	<p>This bit indicates when an inconsistency occurs between the transmitted and the received bit in a message.</p> <p>This bit is not set by a transmitter in case of arbitration field or ACK slot, or in case of a node sending a passive error flag that detects dominant bits.</p> <p>1 At least one bit sent as recessive is received as dominant 0 No such occurrence</p>
14 BIT0_ERR	<p>This bit indicates when an inconsistency occurs between the transmitted and the received bit in a message.</p> <p>1 At least one bit sent as dominant is received as recessive 0 No such occurrence</p>
13 ACK_ERR	<p>This bit indicates that an Acknowledge Error has been detected by the transmitter node, i.e., a dominant bit has not been detected during the ACK SLOT.</p> <p>1 An ACK error occurred since last read of this register 0 No such occurrence</p>
12 CRC_ERR	<p>This bit indicates that a CRC Error has been detected by the receiver node, i.e., the calculated CRC is different from the received.</p> <p>1 A CRC error occurred since last read of this register. 0 No such occurrence</p>
11 FRM_ERR	<p>This bit indicates that a Form Error has been detected by the receiver node, i.e., a fixed-form bit field contains at least one illegal bit.</p> <p>1 A Form Error occurred since last read of this register 0 No such occurrence</p>
10 STF_ERR	<p>This bit indicates that a Stuffing Error has been detected.</p> <p>1 A Stuffing Error occurred since last read of this register. 0 No such occurrence.</p>
9 TX_WRN	<p>This bit indicates when repetitive errors are occurring during message transmission.</p> <p>1 TX_Err_Counter <math>\geq</math> 96 0 No such occurrence</p>
8 RX_WRN	<p>This bit indicates when repetitive errors are occurring during message reception.</p> <p>1 Rx_Err_Counter <math>\geq</math> 96 0 No such occurrence</p>
7 IDLE	<p>This bit indicates when CAN bus is in IDLE state. Refer to <a href="#">Table 43-21</a>.</p>

Table continues on the next page...

**FLEXCANx\_ESR1 field descriptions (continued)**

Field	Description
	<p>1 CAN bus is now IDLE 0 No such occurrence</p>
6 TX	<p>This bit indicates if FLEXCAN is transmitting a message. Refer to <a href="#">Table 43-21</a>.</p> <p>1 FLEXCAN is transmitting a message 0 FLEXCAN is receiving a message</p>
5-4 FLT_CONF	<p>If the LOM bit in the Control Register is asserted, after some delay that depends on the CAN bit timing the FLT_CONF field will indicate "Error Passive". The very same delay affects the way how FLT_CONF reflects an update to ECR register by the Arm. It may be necessary up to one CAN bit time to get them coherent again.</p> <p>Since the Control Register is not affected by soft reset, the FLT_CONF field will not be affected by soft reset if the LOM bit is asserted.</p> <p>This 2-bit field indicates the Confinement State of the FLEXCAN module, as shown in below:</p> <p>00 Error Active 01 Error Passive 1x Bus off</p>
3 RX	<p>This bit indicates if FlexCAN is receiving a message. Refer to <a href="#">Table 43-21</a>.</p> <p>1 FLEXCAN is transmitting a message 0 FLEXCAN is receiving a message</p>
2 BOFF_INT	<p>This bit is set when FLEXCAN enters 'Bus Off' state. If the corresponding mask bit in the Control Register (BOFF_MSK) is set, an interrupt is generated to the Arm. This bit is cleared by writing it to '1'. Writing '0' has no effect.</p> <p>1 FLEXCAN module entered 'Bus Off' state 0 No such occurrence</p>
1 ERR_INT	<p>This bit indicates that at least one of the Error Bits (bits 15-10) is set. If the corresponding mask bit in the Control Register (ERR_MSK) is set, an interrupt is generated to the Arm. This bit is cleared by writing it to '1'. Writing '0' has no effect.</p> <p>1 Indicates setting of any Error Bit in the Error and Status Register 0 No such occurrence</p>
0 WAK_INT	<p>When FLEXCAN is Stop Mode and a recessive to dominant transition is detected on the CAN bus and if the WAK_MSK bit in the MCR Register is set, an interrupt is generated to the Arm. This bit is cleared by writing it to '1'. When SLF_WAK is negated, this flag is masked. Arm must clear this flag before disabling the bit. Otherwise it will be set when the SLF_WAK is set again. Writing '0' has no effect</p> <p>1 Indicates a recessive to dominant transition received on the CAN bus when the FLEXCAN module is in Stop Mode 0 No such occurrence</p>

### 43.9.9 Interrupt Masks 2 Register (FLEXCANx\_IMASK2)

This register allows any number of a range of 32 Message Buffer Interrupts to be enabled or disabled. It contains one interrupt mask bit per buffer, enabling the Arm to determine which buffer generates an interrupt after a successful transmission or reception (i.e. when the corresponding IFLAG2 bit is set).

Address: Base address + 24h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

#### FLEXCANx\_IMASK1 field descriptions

Field	Description
BUF31M_BUF0M	<p>Each bit enables or disables the respective FLEXCAN Message Buffer (MB0 to MB31) Interrupt.</p> <p>Setting or clearing a bit in the IMASK1 Register can assert or negate an interrupt request, if the corresponding IFLAG1 bit is set</p>

**FLEXCANx\_IMASK1 field descriptions (continued)**

Field	Description
1	The corresponding buffer Interrupt is enabled
0	The corresponding buffer Interrupt is disabled

**43.9.11 Interrupt Flags 2 Register (FLEXCANx\_IFLAG2)**

This register defines the flags for 32 Message Buffer interrupts. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG2 bit. If the corresponding IMASK2 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing it to '1'. Writing '0' has no effect. Before updating MCR[MAXMB] field, Arm must treat the IFLAG2 bits which MB value is greater than the MCR[MAXMB] to be updated, otherwise they will keep set and be inconsistent with the amount of MBs available.

Address: Base address + 2Ch offset

**FLEXCANx\_IFLAG2 field descriptions**

Field	Description
BUF63I_BUF32I	Each bit flags the respective FLEXCAN Message Buffer (MB32 to MB63) interrupt.
1	The corresponding buffer has successfully completed transmission or reception
0	No such occurrence

**43.9.12 Interrupt Flags 1 Register (FLEXCANx\_IFLAG1)**

This register defines the flags for 32 Message Buffer interrupts and FIFO interrupts. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG1 bit. If the corresponding IMASK1 bit is set, an interrupt will be generated. The Interrupt flag must be cleared by writing it to '1'. Writing '0' has no effect.

When the RFEN bit in the MCR is set (Rx FIFO enabled), the function of the 8 least significant interrupt flags (BUF7I - BUF0I) is changed to support the FIFO operation. BUF7I, BUF6I and BUF5I indicate operating conditions of the FIFO, while BUF4I to BUF0I are not used. Before enabling the RFEN, Arm must service the IFLAG1 asserted

in the Rx FIFO region (see [Rx FIFO](#)). Otherwise, these IFLAGS will mistakenly show the related MBs now belonging to FIFO as having contents to be serviced. When the RFEN is negated, the FIFO flags must be cleared. The same care must be taken when a RFFN value is selected extending Rx FIFO filters beyond MB7 (see [Control 2 Register \(FLEXCAN\\_CTRL2\)](#)). For example, when RFFN is 0x8, the MB0-23 range is occupied by Rx FIFO filters and related IFLAGS must be cleared.

Before updating MCR[MAXMB] field, Arm must service the IFLAG1 which MB value is greater than the MCR[MAXMB] to be updated, otherwise they will keep set and be inconsistent with the amount of MBs available.

Address: Base address + 30h offset

**FLEXCANx\_IFLAG1 field descriptions**

Field	Description
31–8 BUF31I_BUF8I	Each bit flags the respective FLEXCAN Message Buffer (MB8 to MB31) interrupt.  1 The corresponding MB has successfully completed transmission or reception 0 No such occurrence
7 BUF7I	If the Rx FIFO is not enabled, this bit flags the interrupt for MB7.  If the MCR[RFEN] bit is asserted, this flag indicates that a message was lost because Rx FIFO is full. Note that the flag will not be asserted when the Rx FIFO is full and the message was captured by a Mailbox.  This flag is cleared by the FlexCAN whenever the bit MCR[RFEN] is changed by Arm writes.  1 MB7 completed transmission/reception or FIFO overflow 0 No such occurrence
6 BUF6I	If the Rx FIFO is not enabled, this bit flags the interrupt for MB6.  If the MCR[RFEN] bit is asserted, this flag indicates when the number of unread messages within the Rx FIFO is increased to 5 from 4 due to the reception of a new one, meaning that the Rx FIFO is almost full. Note that if the flag is cleared while the number of unread messages is greater than 4 it will not assert again until the number of unread messages within the Rx FIFO is decreased to equal or less than 4.  This flag is cleared by the FlexCAN whenever the bit MCR[RFEN] is changed by Arm writes.

Table continues on the next page...

**FLEXCANx\_IFLAG1 field descriptions (continued)**

Field	Description
	1 MB6 completed transmission/reception or FIFO almost full 0 No such occurrence
5 BUF5I	If the Rx FIFO is not enabled, this bit flags the interrupt for MB5. If the Rx FIFO is enabled, this flag indicates that at least one frame is available to be read from the Rx FIFO.  This flag is cleared by the FlexCAN whenever the bit MCR[RFEN] is changed by Arm writes.  1 MB5 completed transmission/reception or frames available in the FIFO 0 No such occurrence
BUF4I_BUF0I	If the Rx FIFO is not enabled, these bits flag the interrupts for MB0 to MB4 . If the Rx FIFO is enabled, these flags are not used and must be considered as reserved locations.  These flags are cleared by the FlexCAN whenever the bit MCR[RFEN] is changed by Arm writes.  1 Corresponding MB completed transmission/reception 0 No such occurrence

**43.9.13 Control 2 Register (FLEXCANx\_CTRL2)**

This register contains control bits for CAN errors, FIFO features and mode selection.

**Table 43-22. Rx FIFO Filters**

RFFN[3:0]	Number of Rx FIFO filters	Message Buffers occupied by Rx FIFO and ID Filter Table	Remaining Available Mailboxes <sup>1</sup>	Rx FIFO ID Filter Table Elements Affected by Rx Individual Masks <sup>2</sup>	Rx FIFO ID Filter Table Elements Affected by Rx FIFO Global Mask <sup>2</sup>

0xF	128	MB 0-37	MB 38-63	Elements 0-31	Elements 32-127

1. The number of the last remaining available mailboxes is defined by the MCR[MAXMB] field.  
2. If Rx Individual Mask Registers are not enabled then all Rx FIFO filters are affected by the Rx FIFO Global Mask.

Each group of eight filters occupies a memory space equivalent to two Message Buffers which means that the more filters are implemented the less Mailboxes will be available.

Considering that the Rx FIFO occupies the memory space originally reserved for MB0-5, RFFN should be programmed with a value corresponding to a number of filters not greater than the number of available memory words which can be calculated as follows:

$$(\text{SETUP\_MB} - 6) \times 4$$

where SETUP\_MB is MAXMB.

The number of remaining Mailboxes available will be:

$$\text{SETUP\_MB} - 8 - (\text{RFFN} \times 2)$$

If the Number of Rx FIFO Filters programmed through RFFN exceeds the SETUP\_MB value, the exceeding ones will not be functional. Unshaded regions in [Table 43-23](#) indicate the valid combinations of MAXMB, RFEN and RFFN, shaded regions are not functional.

**FLEXCANx\_CTRL2 field descriptions**

Field	Description
31 -	must be written as 0
30-29 -	This field is reserved. Reserved

Table continues on the next page...

## FLEXCANx\_CTRL2 field descriptions (continued)

Field	Description
28 WRMFRZ	<p>Enable unrestricted write access to FlexCAN memory in Freeze mode. This bit can only be written in Freeze mode and has no effect out of Freeze mode.</p> <p>1 Enable unrestricted write access to FlexCAN memory 0 Keep the write access restricted in some regions of FlexCAN memory</p>
27–24 RFFN	<p>This 4-bit field defines the number of Rx FIFO filters according to <a href="#">Table 43-22</a>. The maximum selectable number of filters is determined by the Arm. This field can only be written in Freeze mode as it is blocked by hardware in other modes. RFFN defines a number of Message Buffers occupied by Rx FIFO and ID Filter (see <a href="#">Table 43-22</a>) that <b>may not exceed</b> the number of available Mailboxes present in module, defined by MCR[MAXMB]. Default RFFN value is 0x0, which leads to a total of 8 Rx FIFO filters, occupies the first 8 Message Buffers (MB 0-7) and makes available the next Message Buffers (MB 8-63) for Mailboxes. As a second example, when RFFN is set to 0xD, there will be 112 Rx FIFO filters, located in MB 0-33, and MB 34-63 are available for Mailboxes. Notice that, in this case, individual masks (RXIMR) will just cover Rx FIFO filters in 0-31 range, and filters 32-111 will use RXFGMASK. In case of reducing the number of last Message Buffers, MCR[MAXMB] (see <a href="#">Module Configuration Register (FLEXCAN_MCR)</a>) can be adjusted by the application to minimum of 33, in order to give room to the Rx FIFO and its ID Filter Table defined by RFFN. On the contrary, if the application sets MCR[MAXMB] to 16, for instance, the maximum RFFN is limited to 0x4. RFFN also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in <a href="#">Table 43-19</a> (see <a href="#">Arbitration and Matching Timing</a>).</p>
23–19 TASD	<p>This 5-bit field indicates how many CAN bits the Tx arbitration process start point can be delayed from the first bit of CRC field on CAN bus. This field can only be written in Freeze mode as it is blocked by hardware in other modes.</p> <p>This field is useful to optimize the transmit performance based on factors such as: peripheral/serial clock ratio, CAN bit timing and number of MBs. The duration of an arbitration process, in terms of CAN bits, is directly proportional to the number of available MBs and CAN baud rate and inversely proportional to the peripheral clock frequency.</p> <p>The optimal arbitration timing is that in which the last MB is scanned right before the first bit of the Intermission field of a CAN frame. Therefore, if there are few MBs and the system/serial clock ratio is high and the CAN baud rate is low then the arbitration can be delayed and vice-versa.</p> <p>If TASD is 0 then the arbitration start is not delayed, thus Arm has less time to configure a Tx MB for the next arbitration, but more time is reserved for arbitration. In the other hand, if TASD is 24 then Arm can configure a Tx MB later and less time is reserved for arbitration.</p> <p>If too little time is reserved for arbitration the FlexCAN may be not able to find winner MBs in time to compete with other nodes for the CAN bus. If the arbitration ends too much time before the first bit of Intermission field then there is a chance that Arm reconfigure some Tx MBs and the winner MB is not the best to be transmitted.</p> <p>The reset value is different on various platforms, according to their peripheral clock frequency, number of MBs and target CAN baud rate.</p> <p>The optimal configuration for TASD can be calculated as:</p>

*Table continues on the next page...*

**FLEXCANx\_CTRL2 field descriptions (continued)**

Field	Description
	$TASD = 25 - \left\{ \frac{f_{CANCLK} \times [MAXMB + 3 - (RFEN \times 8) - (RFEN \times RFFN \times 2)] \times 2}{f_{SYS} \times [1 + (PSEG1 + 1) + (PSEG2 + 1) + (PROPSEG + 1)] \times (PRES DIV + 1)} \right\}$ <p>where:</p> <p><math>f_{CANCLK}</math> is the Protocol Engine (PE) Clock in Hz; PE clock is derived from CAN_CLK_ROOT in CCM. See the Clock controller module.</p> <p><math>f_{SYS}</math> is the peripheral clock in Hz;</p> <p>MAXMB is the value in CTRL1[MAXMB] field;</p> <p>RFEN is the value in CTRL1[RFEN] bit;</p> <p>RFFN is the value in CTRL2[RFFN] field;</p> <p>PSEG1 is the value in CTRL1[PSEG1] field;</p> <p>PSEG2 is the value in CTRL1[PSEG2] field;</p> <p>PROPSEG is the value in CTRL1[PROPSEG] field;</p> <p>PRES DIV is the value in CTRL1[PRES DIV] field.</p> <p>Please refer to <a href="#">Arbitration process</a> and <a href="#">Protocol Timing</a> for more details.</p>
<p>18 MRP</p>	<p>If this bit is set the matching process starts from the Mailboxes and if no match occurs the matching continues on the Rx FIFO. This bit can only be written in Freeze mode as it is blocked by hardware in other modes.</p> <p>1 Matching starts from Mailboxes and continues on Rx FIFO 0 Matching starts from Rx FIFO and continues on Mailboxes</p>
<p>17 RRS</p>	<p>If this bit is asserted Remote Request Frame is submitted to a matching process and stored in the corresponding Message Buffer in the same fashion of a Data Frame. No automatic Remote Response Frame will be generated.</p> <p>If this bit is negated the Remote Request Frame is submitted to a matching process and an automatic Remote Response Frame is generated if a Message Buffer with CODE=0b1010 is found with the same ID.</p> <p>This bit can only be written in Freeze mode as it is blocked by hardware in other modes.</p> <p>1 Remote Request Frame is stored 0 Remote Response Frame is generated</p>
<p>16 EACEN</p>	<p>This bit controls the comparison of IDE and RTR bits within Rx Mailboxes filters with their corresponding bits in the incoming frame by the matching process. This bit does not affect matching for Rx FIFO. This bit can only be written in Freeze mode as it is blocked by hardware in other modes.</p> <p>1 Enables the comparison of both Rx Mailbox filter's IDE and RTR bit with their corresponding bits within the incoming frame. Mask bits do apply. 0 Rx Mailbox filter's IDE bit is always compared and RTR is never compared despite mask bits.</p>
<p>-</p>	<p>This field is reserved.</p>

### 43.9.14 Error and Status 2 Register (FLEXCANx\_ESR2)

This register reflects various interrupt flags and some general status.

Address: Base address + 38h offset

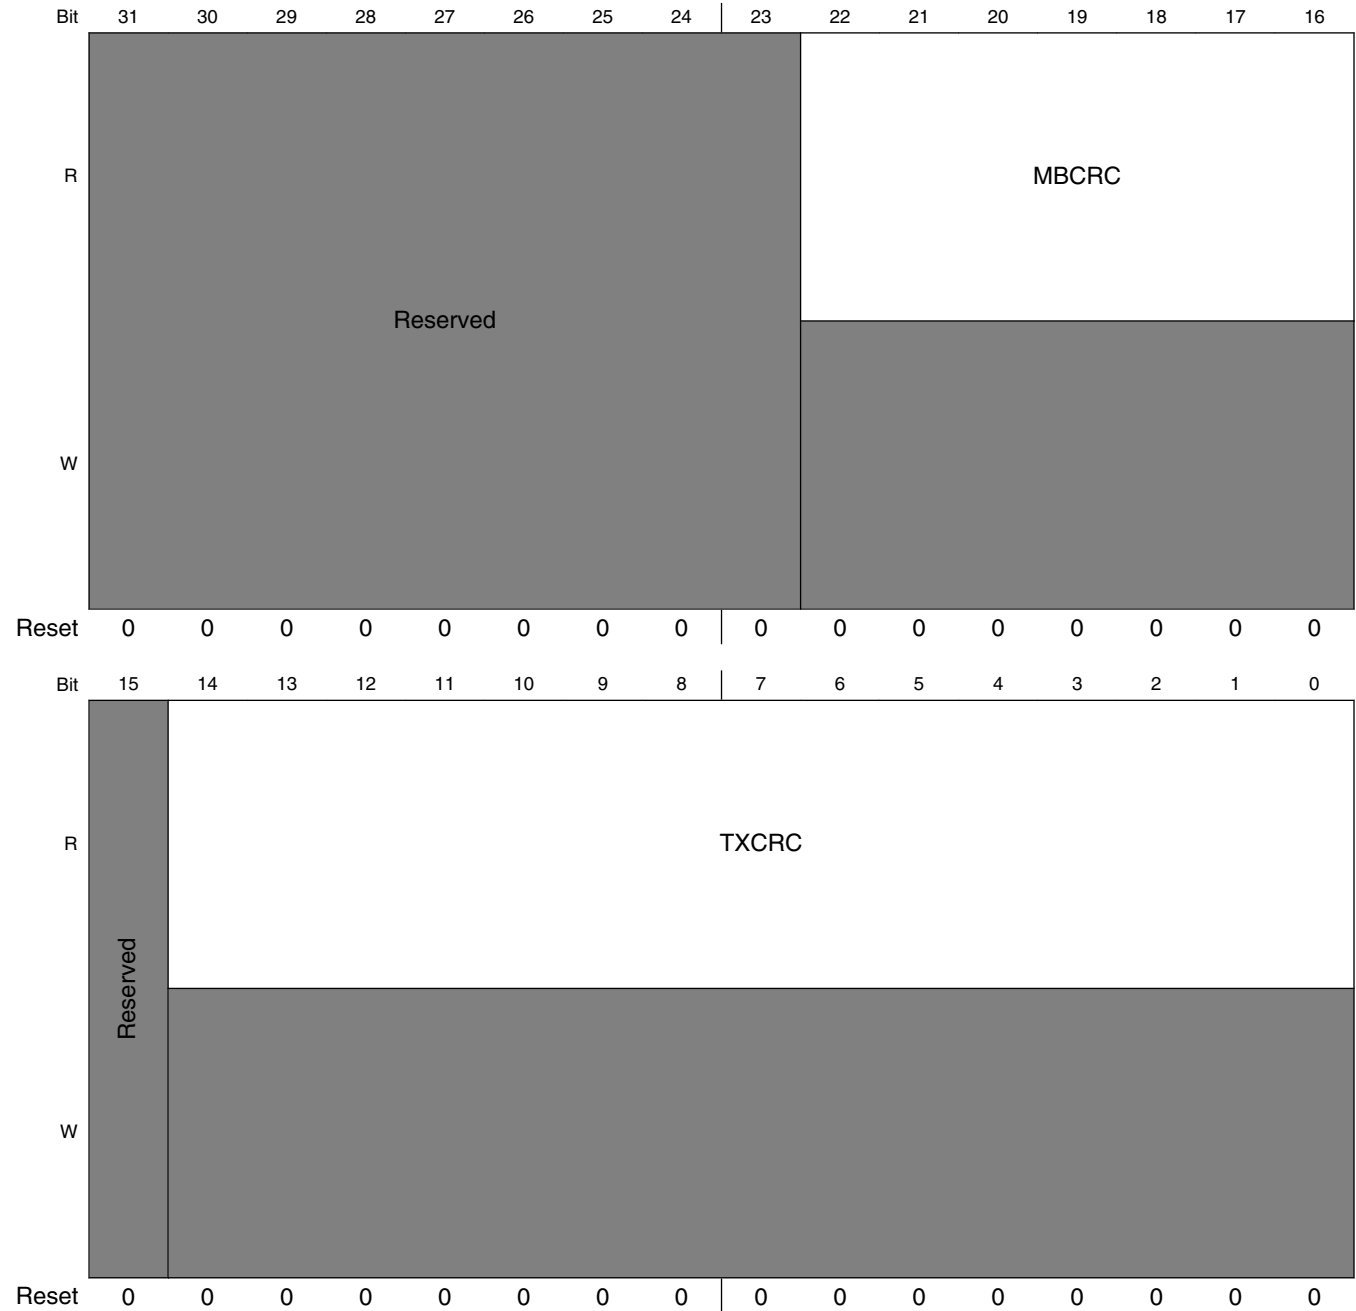

## FLEXCANx\_ESR2 field descriptions

Field	Description
31–23 -	This field is reserved. Reserved
22–16 LPTM	If ESR2[VPS] is asserted, this 7-bit field indicates the lowest number inactive Mailbox (refer to IMB bit description). If there is no inactive Mailbox then the Mailbox indicated depends on CTRL1[LBUF] bit value. If CTRL1[LBUF] bit is negated then the Mailbox indicated is the one which has the greatest arbitration value (see <a href="#">Highest Mailbox priority first</a> ). If CTRL1[LBUF] bit is asserted then the Mailbox indicated is the highest number active Tx Mailbox. If a Tx Mailbox is being transmitted it is not considered in LPTM calculation. If ESR2[IMB] is not asserted and a frame is transmitted successfully, LPTM is updated with its Mailbox number.
15 -	This field is reserved. Reserved
14 VPS	This bit indicates whether IMB and LPTM contents are currently valid or not. VPS is asserted upon every complete Tx arbitration process unless the Arm writes to Control and Status word of a Mailbox that has already been scanned (i.e. it is behind Tx Arbitration Pointer) during the Tx arbitration process. If there is no inactive Mailbox and only one Tx Mailbox which is being transmitted then VPS is not asserted. VPS is negated upon the start of every Tx arbitration process or upon a write to Control and Status word of any Mailbox. ESR2[VPS] is not affected by any Arm write into Control Status (C/S) of a MB which is blocked by abort mechanism. When MCR[AEN] is asserted, the abort code write in C/S of a MB that is been transmitted (pending abort), or any write attempt into a Tx MB with IFLAG set is blocked.  1 Contents of IMB and LPTM are valid 0 Contents of IMB and LPTM are invalid
13 IMB	If ESR2[VPS] is asserted, this bit indicates whether there is any inactive Mailbox (CODE field is either 0b1000 or 0b0000).  This bit is asserted in the following cases: (1) During arbitration, if a LPTM is found and it is inactive. (2) If IMB is not asserted and a frame is transmitted successfully. (3) This bit is cleared in all start of arbitration (see <a href="#">Arbitration process</a> ).  LPTM mechanism have the following behavior: if a MB is successfully transmitted and ESR2[IMB]=0 (no inactive Mailbox), then ESR2[VPS] and ESR2[IMB] are asserted and the index related to the MB just transmitted is loaded into ESR2[LPTM].  1 If ESR2[VPS] is asserted, there is at least one inactive Mailbox. LPTM content is the number of the first one. 0 If ESR2[VPS] is asserted, the ESR2[LPTM] is not an inactive Mailbox.
-	This field is reserved. Reserved

### 43.9.15 CRC Register (FLEXCANx\_CRCR)

This register provides information about the CRC of transmitted messages

Address: Base address + 44h offset

## FLEXCANx\_CRCR field descriptions

Field	Description
31–23 -	This field is reserved. Reserved
22–16 MBCRC	This field indicates the number of the Mailbox corresponding to the value in TXCRC field.
15 -	This field is reserved. Reserved
TXCRC	This field indicates the CRC value of the last message transmitted. This field is updated at the same time the Tx Interrupt Flag is asserted.

### 43.9.16 Rx FIFO Global Mask Register (FLEXCANx\_RXFGMASK)

If Rx FIFO is enabled RXFGMASK is used to mask the Rx FIFO ID Filter Table elements that do not have a corresponding RXIMR according to CTRL2[RFFN] field setting.

This register can only be written in Freeze Mode as it is blocked by hardware in other modes.

**Table 43-24. Rx FIFO Global Mask usage**

Rx FIFO ID Filter Table Elements Format (MCR[IDAM])	Identifier Acceptance Filter fields					
	RTR	IDE	RXIDA	RXIDB	RXIDC	reserved
A	FGM[31]	FGM[30]	FGM[29:1]	-	-	FGM[0]
B	FGM[31] FGM[15]	FGM[30] FGM[14]	-	FGM[29:16] FGM[13:0] 1	-	-
C	-	-	-	-	FGM[31:24] FGM[23:16] FGM[15:8] FGM[7:0] 2	-

1. If MCR[IDAM] field is equivalent to the format B only the fourteen most significant bits of the Identifier of the incoming frame are compared with the Rx FIFO filter.
2. If MCR[IDAM] field is equivalent to the format C only the eight most significant bits of the Identifier of the incoming frame are compared with the Rx FIFO filter.

Field	Description
FGM31_FGM0	<p>These bits mask the ID Filter Table elements bits in a perfect alignment. <a href="#">Rx FIFO Global Mask Register (FLEXCAN_RXFGMASK)</a> shows in detail which FGM bits mask each IDAF field. Clear this register has the effect of disabling the ID Filter.</p> <p>1 The corresponding bit in the filter is checked 0 The corresponding bit in the filter is "don't care"</p>

## 43.9.17 Rx FIFO Information Register (FLEXCANx\_RXFIR)

RXFIR provides information on Rx FIFO.

This register is the port through which Arm accesses the output of the RXFIR FIFO located in RAM. The RXFIR FIFO is written by the FlexCAN whenever a new message is moved into the Rx FIFO as well as its output is updated whenever the output of the Rx FIFO is updated with the next message. Refer to [Rx FIFO](#) to find instructions on reading this register.

Address: Base address + 4Ch offset

#### FLEXCANx\_DBG2 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15 APP	Arbitration Process in Progress  Indicates whether the arbitration process is in progress or not. It is set when the first message buffer is accessed and kept asserted as long as the arbitration is ongoing. APP is negated when the highest priority MB is found or when the last MB is accessed or if the arbitration process is interrupted.  0 No matching process ongoing. 1 Matching process is in progress.
14–8 TAP	Tx Arbitration Pointer  This 7-bit field indicates the number of the MB that is currently being accessed by the arbitration process.
7 MPP	Matching Process in Progress  Indicates whether the matching process is in progress or not. It is set when the first matching element is accessed and kept asserted when the matching is ongoing. MPP is negated when a match occurs or when the last matching element is accessed or if the matching process is interrupted.  0 No matching process ongoing. 1 Matching process is in progress.
RMP	Rx Matching Pointer  This 7-bit field indicates the number of the MB that is currently being accessed by the matching process.

### 43.9.20 Rx Individual Mask Registers (FLEXCANx\_RXIMRn)

RXIMR are used as acceptance masks for ID filtering in Rx MBs and the Rx FIFO . If the Rx FIFO is not enabled, one mask register is provided for each available Mailbox, providing ID masking capability on a per Mailbox basis.

When the Rx FIFO is enabled (MCR[RFEN] bit is asserted), up to 32 Rx Individual Mask Registers can apply to the Rx FIFO ID Filter Table elements on a one-to-one correspondence depending on CTRL2[RFFN] setting. Refer to [Control 2 Register \(FLEXCAN\\_CTRL2\)](#) for details .

RXIMR can only be written by the Arm while the module is in Freeze Mode, otherwise they are blocked by hardware .

The Individual Rx Mask Registers are not affected by reset and must be explicitly initialized prior to any reception.

Address: Base address + 880h offset + (4d × i), where i=0d to 63d

#### FLEXCANx\_RXIMRn field descriptions

Field	Description
MI31_MIO	<p>These bits mask both Mailbox filter and Rx FIFO ID Filter Table element in distinct ways.</p> <p>For Mailbox filter refer to <a href="#">Rx Mailboxes Global Mask Register (FLEXCAN_RXMGMASK)</a>.</p> <p>For Rx FIFO ID Filter Table element refer to <a href="#">Rx FIFO Global Mask Register (FLEXCAN_RXFGMASK)</a>.</p> <p>1 The corresponding bit in the filter is checked                      0 the corresponding bit in the filter is "don't care"</p>

### 43.9.21 Glitch Filter Width Registers (FLEXCANx\_GFWR)

The Glitch Filter just takes effects when FLEXCAN enters the STOP mode.

Address: Base address + 9E0h offset

**FLEXCANx\_GFWR field descriptions**

Field	Description
31–8 Reserved	This read-only field is reserved and always has the value 0.
GFWR	<p>It determines the Glitch Filter Width. The width will be divided from Oscillator clock by GFWR values. By default, it is 5.33 <math>\mu</math>s when the oscillator is 24 MHz.</p> <p>Filter Pulse Width = [(GFWR FIELD + 1) x (1 / Osc. Frequency)]</p>

### 44.2 Introduction

The FlexCAN module is a communication controller implementing the CAN protocol according to the ISO 11898-1 standard and CAN 2.0 B protocol specifications. A general block diagram is shown in the following figure, which describes the main subblocks implemented in the FlexCAN module, including one associated memory for storing message buffers, Receive Global Mask registers, Receive Individual Mask registers, Receive FIFO filters, and Receive FIFO ID filters. The functions of the submodules are described in subsequent sections.

#### NOTE

Legacy Rx FIFO cannot be used in FD mode.

**Figure 44-1. FlexCAN block diagram**

## 44.2.1 Overview

The CAN protocol was primarily designed to be used as a vehicle serial data bus, meeting the specific requirements of this field:

- Real-time processing
- Reliable operation in the EMI environment of a vehicle
- Cost-effectiveness
- Required bandwidth

The FlexCAN module is a full implementation of the CAN protocol specification, the CAN with Flexible Data rate (CAN FD) protocol and the CAN 2.0 version B protocol, which supports both standard and extended message frames and long payloads up to 64 bytes transferred at faster rates up to 8 Mbps. The message buffers are stored in an embedded RAM dedicated to the FlexCAN module. See the chip configuration details for the actual number of message buffers configured in the chip.

The Protocol Engine (PE) submodule manages the serial communication on the CAN bus:

- Requesting RAM access for receiving and transmitting message frames
- Validating received messages
- Performing error handling
- Detecting CAN FD messages

The Controller Host Interface (CHI) sub-module handles message buffer selection for reception and transmission, taking care of arbitration and ID matching algorithms for both CAN FD and non-CAN FD message formats.

The Bus Interface Unit (BIU) sub-module controls the access to and from the internal interface bus, in order to establish connection to the CPU and to other blocks. Clocks, address and data buses, interrupt outputs, DMA and test signals are accessed through the BIU.

## 44.2.2 FlexCAN module features

The FlexCAN module includes these distinctive features:

- Full implementation of the CAN with Flexible Data Rate (CAN FD) protocol specification and CAN protocol specification, Version 2.0 B
  - Standard data frames
  - Extended data frames
  - Zero to sixty four bytes data length
  - Programmable bit rate (see the chip-specific FlexCAN information for the specific maximum rate configuration)
  - Content-related addressing
- Compliant with the ISO 11898-1 standard
- Flexible mailboxes configurable to store 0 to 8, 16, 32 or 64 bytes data length
- Each mailbox configurable as receive or transmit, all supporting standard and extended messages
- Individual Rx Mask registers per mailbox
- Full-featured legacy Rx FIFO with storage capacity for up to six frames and automatic internal pointer handling with DMA support

- Full-featured enhanced Rx FIFO with storage capacity for up to 32 CAN FD frames and automatic internal pointer handling with DMA support
- Transmission abort capability
- Flexible message buffers (MBs), totaling 64 message buffers of 8 bytes data length each, configurable as Rx or Tx
- Programmable clock source to the CAN Protocol Interface, either peripheral clock or oscillator clock
- RAM not used by reception or transmission structures can be used as general purpose RAM space
- Listen-Only mode capability
- Programmable Loop-Back mode supporting self-test operation
- Programmable transmission priority scheme: lowest ID, lowest buffer number, or highest priority
- Time stamp based on 32-bit free-running timer, with an optional external time tick
- Global network time, synchronized by a specific message
- Maskable interrupts
- Independence from the transmission medium (an external transceiver is assumed)
- Short latency time due to an arbitration scheme for high-priority messages
- Low power modes, with programmable wake up on bus activity
- Transceiver Delay Compensation feature when transmitting CAN FD messages at faster data rates
- Remote request frames may be handled automatically or by software
- CAN bit time settings and configuration bits can only be written in Freeze mode
- Tx mailbox status (Lowest priority buffer or empty buffer)
- Identifier Acceptance Filter Hit Indicator (IDHIT) register for received frames
- SYNCH bit available in Error in Status 1 register to inform that the module is synchronous with CAN bus
- CRC status for transmitted message
- Legacy Rx FIFO Global Mask register

- Selectable priority between mailboxes and Rx FIFO during matching process
- Powerful legacy Rx FIFO ID filtering, capable of matching incoming IDs against either 128 extended, 256 standard, or 512 partial (8 bit) IDs, with up to 32 individual masking capability
- Powerful Enhanced Rx FIFO ID filtering, capable of matching incoming IDs against either 64 extended or 128 standard ID filter elements with three filtering schemes: mask + filter, range, and two filters without mask.
- 100% backward compatibility with previous FlexCAN version

### 44.2.3 Modes of operation

The FlexCAN module has these functional modes:

- Normal mode (User or Supervisor):

In Normal mode, the module operates receiving and/or transmitting message frames, errors are handled normally, and all CAN Protocol functions are enabled. User and Supervisor Modes differ in the access to some restricted control registers.

- Freeze mode:

Freeze mode is enabled when the FRZ bit in MCR is asserted. If enabled, Freeze mode is entered when MCR[HALT] is set or when Debug mode is requested at chip level and MCR[FRZ\_ACK] is asserted by the FlexCAN. In this mode, no transmission or reception of frames is done and synchronicity to the CAN bus is lost. See [Freeze mode](#) for more information.

- Loop-Back mode:

The module enters this mode when the LPB field in the Control 1 Register is asserted. In this mode, FlexCAN performs an internal loop back that can be used for self-test operation. The bit stream output of the transmitter is internally fed back to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic '1'). FlexCAN behaves as it normally does when transmitting and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field to ensure proper reception of its own message. Both transmit and receive interrupts are generated.

- Listen-Only mode:

The module enters this mode when the LOM field in the Control 1 Register is asserted. In this mode, transmission is disabled, all error counters are frozen, and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station will be received. If FlexCAN detects a message that has not been acknowledged, it will flag a BIT0 error (without changing the REC), as if it was trying to acknowledge the message.

- CAN FD Active mode:

In this mode, FlexCAN is capable of transmitting and receiving all messages formatted according to the CAN FD Protocol and CAN 2.0 Protocol 2.0 in a interleaved fashion. The CPU can set the FlexCAN into CAN FD Active mode by configuring the MCR[FDEN] bit field in Freeze Mode.

It is important to know which features are available in CAN FD active mode. This table lists the differences between FD and classical modes.

**Table 44-2. Differences between CAN classical and CAN FD**

Feature	CAN classical	CAN FD
Legacy Rx FIFO DMA	Yes	No
Legacy Rx FIFO	Yes	No
Enhanced Rx FIFO DMA	Yes	Yes
Enhanced Rx FIFO	Yes	Yes

For low-power operation, the FlexCAN module has:

- Module Disable mode:

This low-power mode is entered when the MDIS bit in the MCR Register is asserted by the CPU and the LPM\_ACK is asserted by the FlexCAN. When disabled, the module requests to disable the clocks to the CAN Protocol Engine and Controller Host Interface submodules. Exit from this mode is done by negating the MDIS bit in the MCR register. See [Module Disable mode](#) for more information.

- Doze mode:

This low power mode is entered when the DOZE bit in MCR is asserted and Doze mode is requested at chip level and the LPM\_ACK bit in the MCR Register is asserted by the FlexCAN. When in Doze mode, the module requests to disable the clocks to the CAN Protocol Engine and the CAN Controller-Host Interface sub-

modules. Exit from this mode happens when the DOZE bit in MCR is negated, when the chip is removed from Doze mode, or when activity is detected on the CAN bus and the Self Wake Up mechanism is enabled. See [Doze mode](#) for more information.

- Stop mode:

This low power mode is entered when Stop mode is requested at chip level and the LPM\_ACK bit in the MCR Register is asserted by the FlexCAN. When in Stop Mode, the module puts itself in an inactive state and then informs the CPU that the clocks can be shut down globally. Exit from this mode happens when the Stop mode request is removed, or when activity is detected on the CAN bus and the Self Wake Up mechanism is enabled. See [Stop mode](#) for more information.

## 44.3 FlexCAN signal descriptions

The FlexCAN module has two I/O signals connected to the external chip pins. These signals are summarized in the following table and described in more detail in the next subsections.

**Table 44-3. FlexCAN signal descriptions**

Signal	Description	I/O
CAN Rx	CAN Receive Pin	Input
CAN Tx	CAN Transmit Pin	Output

### 44.3.1 CAN Rx

This pin is the receive pin from the CAN bus transceiver. Dominant state is represented by logic level 0. Recessive state is represented by logic level 1.

### 44.3.2 CAN Tx

This pin is the transmit pin to the CAN bus transceiver. Dominant state is represented by logic level 0. Recessive state is represented by logic level 1.

## 44.4 Functional description

The FlexCAN module is a CAN protocol engine with a very flexible mailbox system for transmitting and receiving CAN frames. The mailbox system is composed by a set of Message Buffers (MB) that store configuration and control data, time stamp, message ID and data (see [Message buffer structure](#)). The memory corresponding to the first 38 MBs can be configured to support a Legacy FIFO reception scheme with a powerful ID filtering mechanism, capable of checking incoming frames against a table of IDs (up to 128 extended IDs or 256 standard IDs or 512 8-bit ID slices), with individual mask register for up to 32 ID Filter Table elements.

For Classical CAN frames, simultaneous reception through Legacy FIFO and mailbox is supported. For CAN FD frames, reception is supported through mailboxes and Enhanced Rx FIFO. For mailbox reception, a matching algorithm makes it possible to store received frames only into MBs that have the same ID programmed on its ID field. A masking scheme makes it possible to match the ID programmed on the MB with a range of IDs on received CAN frames. For transmission, an arbitration algorithm decides the prioritization of MBs to be transmitted based on the message ID (optionally augmented by 3 local priority bits) or the MB ordering.

Before proceeding with the functional description, an important concept must be explained. A Message Buffer is said to be "active" at a given time if it can participate in both the Matching and Arbitration processes. An Rx MB with a 0b0000 code is inactive (refer to [Table 44-34](#)). Similarly, a Tx MB with a 0b1000 or 0b1001 code is also inactive (refer to [Table 44-35](#)).

The FlexCAN module is also able to receive and transmit messages in CAN FD format. The Message Buffers are sized to adequately store the quantity of data bytes selected by the MBDSRn bit fields in CAN\_FDCTRL register. The quantity of FD MBs available for a given quantity of data bytes is described CAN\_FDCTRL register. See also [FlexCAN Memory Partition for CAN FD](#).

### 44.4.1 Transmit process

To transmit a CAN frame, the CPU must prepare a Message Buffer for transmission by executing the following procedure:

1. Check whether the respective interrupt bit is set and clear it.
2. If the MB is active (transmission pending), write the ABORT code (0b1001) to the CODE field of the Control and Status word to request an abort of the transmission.

3. Wait for the corresponding IFLAG bit to be asserted by polling the CAN\_IFLAG register, or by the interrupt request if enabled by the respective IMASK bit.
4. Read back the CODE field to check if the transmission was aborted or transmitted (see [Transmission abort mechanism](#)).
5. Clear the corresponding interrupt flag.
6. Write the ID register (containing the local priority if enabled via MCR[LPRIO\_EN]).
7. Write payload data bytes.
8. Configure the Control and Status word with the desired configuration.
  - Set ID type via MB\_CS[IDE].
  - Set Remote Transmission Request (if needed) via MB\_CS[RTR].
  - If CAN\_MCR[FDEN] is enabled, also configure the MB\_CS[EDL] and MB\_CS[BRS] fields. For details about the relationship between the written value and transmitted value of the MB\_CS[ESI] field, see [Table 44-14](#).<sup>1</sup>
  - Activate the message buffer to transmit the CAN frame by setting MB\_CS[CODE] to 0xC.
  - Set Data Length Code in bytes via MB\_CS[DLC]. See [Table 44-37](#) for detailed information.

When the MB is activated, it participates in the arbitration process and is eventually transmitted according to its priority. When the DLC value stored in the MB selected for transmission is larger than the respective MB payload size, FlexCAN adds the necessary number of bytes with constant 0xCC pattern to complete the expected DLC.

At the end of the successful transmission:

- The value of the Free Running Timer is written into the Time Stamp field.
- The CODE field in the Control and Status word is updated.
- Both CAN\_CRC and CAN\_FDCRC registers are updated.
- A status flag is set in the Interrupt Flag register.
- An interrupt is generated if allowed by the corresponding Interrupt Mask Register bit.

The new CODE field after transmission depends on the code that was used to activate the MB (see [Table 44-34](#) and [Table 44-35](#) in [Message buffer structure](#)).

When the Abort feature is enabled (CAN\_MCR[AEN] is asserted), after the Interrupt Flag is asserted for a Mailbox configured as transmit buffer, the Mailbox is blocked. Therefore the CPU is not able to update it until the Interrupt Flag is negated by the CPU. This means that the CPU must clear the corresponding IFLAG bit before starting to prepare this MB for a new transmission or reception.

---

1. The ESI field does not need to be written, and will automatically be transmitted dominant by error active nodes and recessive by error passive nodes. Note that there is an exception if the FlexCAN is operating as a network gateway: In that case, the CPU writes the MB\_CS[ESI] bit according to the error status of the node which sent the message.

**NOTE**

If backwards compatibility is desired (CAN\_MCR[AEN] bit is negated), write the INACTIVE code (0b1000) to the CODE field to inactivate the MB. However, in this case the pending frame may be transmitted without notification (see [Mailbox inactivation](#)).

## 44.4.2 Arbitration process

The arbitration process scans the Mailboxes searching the Tx one that holds the message to be sent in the next opportunity. This Mailbox is called the *arbitration winner*.

The scan starts from the lowest number Mailbox and runs toward the higher ones.

The arbitration process is triggered in the following events:

- From the CRC field of the CAN frame. The start point depends on the CAN\_CTRL2[TASD] field value.
- During the Error Delimiter field of a CAN frame.
- During the Overload Delimiter field of a CAN frame.
- When the winner is inactivated and the CAN bus has still not reached the first bit of the Intermission field.
- When there is CPU write to the C/S word of a winner MB and the CAN bus has still not reached the first bit of the Intermission field.
- When CHI is in Idle state and the CPU writes to the C/S word of any MB.
- When FlexCAN exits Bus Off state.
- Upon leaving Freeze mode or Low Power mode.

If the arbitration process does not manage to evaluate all Mailboxes before the CAN bus has reached the first bit of the Intermission field the temporary arbitration winner is invalidated and the FlexCAN will not compete for the CAN bus in the next opportunity.

The arbitration process selects the winner among the active Tx Mailboxes at the end of the scan according to both CAN\_CTRL1[LBUF] and CAN\_MCR[LPRIOEN] bits settings.

### 44.4.2.1 Lowest-number Mailbox first

If CAN\_CTRL1[LBUF] bit is asserted the first (lowest number) active Tx Mailbox found is the arbitration winner. CAN\_MCR[LPRIOEN] bit has no effect when CAN\_CTRL1[LBUF] is asserted.

### 44.4.2.2 Highest-priority Mailbox first

If CAN\_CTRL1[LBUF] bit is negated, then the arbitration process searches the active Tx Mailbox with the highest priority, which means that this Mailbox's frame would have a higher probability to win the arbitration on CAN bus when multiple external nodes compete for the bus at the same time.

The sequence of bits considered for this arbitration is called the *arbitration value* of the Mailbox. The highest-priority Tx Mailbox is the one that has the lowest arbitration value among all Tx Mailboxes.

If two or more Mailboxes have equivalent arbitration values, the Mailbox with the lowest number is the arbitration winner.

The composition of the arbitration value depends on CAN\_MCR[LPRIOEN] bit setting.

#### 44.4.2.2.1 Local Priority disabled

If CAN\_MCR[LPRIOEN] bit is negated the arbitration value is built in the exact sequence of bits as they would be transmitted in a CAN frame (see the following table) in such a way that the Local Priority is disabled.

**Table 44-4. Composition of the arbitration value when Local Priority is disabled**

Format	Mailbox Arbitration Value (32 bits)				
Standard (IDE = 0)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	- (18 bits)	- (1 bit)
Extended (IDE = 1)	Extended ID[28:18] (11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0] (18 bits)	RTR (1 bit)

#### 44.4.2.2.2 Local Priority enabled

If Local Priority is desired CAN\_MCR[LPRIOEN] must be asserted. In this case the Mailbox PRIO field is included at the very left of the arbitration value (see the following table).

**Table 44-5. Composition of the arbitration value when Local Priority is enabled**

Format	Mailbox Arbitration Value (35 bits)					
Standard (IDE = 0)	PRI0 (3 bits)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	- (18 bits)	- (1 bit)
Extended (IDE = 1)	PRI0 (3 bits)	Extended ID[28:18] (11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0] (18 bits)	RTR (1 bit)

As the PRI0 field is the most significant part of the arbitration value Mailboxes with low PRI0 values have higher priority than Mailboxes with high PRI0 values regardless the rest of their arbitration values.

Note that the PRI0 field is not part of the frame on the CAN bus. Its purpose is only to affect the internal arbitration process.

### 44.4.2.3 Arbitration process (continued)

After the arbitration winner is found, its content is copied to a hidden auxiliary MB called Tx Serial Message Buffer (Tx SMB), which has the same structure as a normal MB but is not user accessible. This operation is called move-out and after it is done, write access to the C/S word of the corresponding MB is blocked (if the AEN bit in CAN\_MCR register is asserted). Write access is restored in the following events:

- After the MB is transmitted and the corresponding IFLAG bit is cleared by the CPU
- FlexCAN enters in Freeze mode or Bus Off
- FlexCAN loses the bus arbitration or there is an error during the transmission

At the first opportunity window on the CAN bus, the message on the Tx SMB is transmitted according to the CAN protocol rules.

Arbitration process can be triggered in the following situations:

- During Rx and Tx frames from CAN CRC field to end of frame. CAN\_CTRL2[TASD] bit value may be changed to optimize the arbitration start point.
- During CAN BusOff state from TX\_ERR\_CNT=124 to 128. CAN\_CTRL2[TASD] bit value may be changed to optimize the arbitration start point.
- During C/S write by CPU in BusIdle. First C/S write starts arbitration process and a second C/S write during this same arbitration restarts the process. If other C/S writes are performed, Tx arbitration process is pending. If there is no arbitration winner after the arbitration process has finished, then the TX arbitration machine begins a new arbitration process. If there is a pending arbitration and BusIdle state starts then an arbitration process is triggered. In this case the first and second C/S write in

BusIdle will not restart the arbitration process. It is possible that there is not enough time to finish arbitration in WaitForBusIdle state and the next state is Idle. In this case the scan is not interrupted, and it is completed during BusIdle state. During this arbitration C/S write does not cause arbitration restart.

- Arbitration winner deactivation during a valid arbitration window.
- Upon exiting Freeze mode (first bit of the WaitForBusIdle state). If there is a re-synchronization during WaitForBusIdle, the arbitration process is restarted.

Arbitration process stops in the following situations:

- All Mailboxes were scanned
- A Tx active Mailbox is found in case of Lowest Buffer feature enabled
- Arbitration winner inactivation or abort during any arbitration process
- There was not enough time to finish Tx arbitration process (for instance, when a deactivation was performed near the end of frame). In this case arbitration process is pending.
- Error or Overload flag in the bus
- Low Power or Freeze mode request in Idle state

Arbitration is considered pending as described below:

- It was not possible to finish arbitration process in time
- C/S write during arbitration if write is performed in a MB whose number is lower than the Tx arbitration pointer
- Any C/S write if there is no Tx Arbitration process in progress
- Rx Match has just updated a Rx Code to Tx Code
- Entering Busoff state

C/S write during arbitration has the following effect:

- If C/S write is performed in the arbitration winner, a new process is restarted immediately.
- If C/S write is performed in a MB whose number is higher than the Tx arbitration pointer, the ongoing arbitration process will scan this MB as normal.

### 44.4.3 Receive process

To be able to receive CAN frames into a Mailbox, the CPU must prepare it for reception by executing the following steps:

1. If the Mailbox is active (either Tx or Rx) inactivate the Mailbox (see [Mailbox inactivation](#)), preferably with a safe inactivation (see [Transmission abort mechanism](#)).

## Functional description

2. Write the ID word
3. Write the EMPTY code (0b0100) to the CODE field of the Control and Status word to activate the Mailbox. No setup is required for EDL, BRS and ESI bits, they are overwritten by the respective bit fields in the received message.

After the MB is activated, it will be able to receive frames that match the programmed filter. At the end of a successful reception, the Mailbox is updated by the *move-in* process (see [Move-in](#)) as follows:

1. The received Data field (8 bytes at most for Classical CAN message format and up to 64 bytes for CAN FD message format) is stored.
2. The received Identifier field is stored.
3. The value of the Free Running Timer at the time of the second bit of frame's Identifier field is written into the Mailbox's Time Stamp field.
4. The received SRR, IDE, RTR, EDL, BRS, ESI and DLC fields are stored.
5. The CODE field in the Control and Status word is updated (see [Table 44-34](#) and [Table 44-35](#) in Section [Message buffer structure](#)).
6. A status flag is set in the Interrupt Flag Register and an interrupt is generated if allowed by the corresponding Interrupt Mask Register bit.

The recommended way for CPU servicing (read) the frame received in an Mailbox is using the following procedure:

1. Read the Control and Status word of that Mailbox.
2. Check if the BUSY bit is deasserted, indicating that the Mailbox is locked. Repeat step 1) while it is asserted. See [Mailbox lock mechanism](#).
3. Read the contents of the Mailbox. Once Mailbox is locked now, its contents won't be modified by FlexCAN Move-in processes. See [Move-in](#).
4. Acknowledge the proper flag at IFLAG registers.
5. Read the Free Running Timer. It is optional but recommended to unlock Mailbox as soon as possible and make it available for reception.

The CPU should poll for frame reception by the status flag bit for the specific Mailbox in one of the IFLAG Registers and not by the CODE field of that Mailbox. Polling the CODE field does not work because once a frame was received and the CPU services the Mailbox (by reading the C/S word followed by unlocking the Mailbox), the CODE field will not return to EMPTY. It will remain FULL, as explained in [Table 44-34](#). If the CPU

tries to workaroud this behavior by writing to the C/S word to force an EMPTY code after reading the Mailbox without a prior *safe inactivation*, a newly received frame matching the filter of that Mailbox may be lost.

### CAUTION

*In summary: never do polling by reading directly the C/S word of the Mailboxes. Instead, read the IFLAG registers.*

Note that the received frame's Identifier field is always stored in the matching Mailbox, thus the contents of the ID field in an Mailbox may change if the match was due to masking. When CAN\_MCR[SRXDIS] bit is asserted, FlexCAN will not store frames transmitted by itself in any MB, even if it contains a matching Rx Mailbox, and no interrupt flag or interrupt signal will be generated. Otherwise, when CAN\_MCR[SRXDIS] bit is deasserted, FlexCAN can receive frames transmitted by itself if there exists a matching Rx Mailbox.

To be able to receive CAN frames through the Legacy Rx FIFO, the CPU must enable and configure the Legacy Rx FIFO during Freeze mode (see [Legacy Rx FIFO](#)). Upon receiving the Frames Available in Legacy Rx FIFO interrupt (see the description of the BUF5I bit "Frames available in Legacy Rx FIFO" bit in the CAN\_IFLAG1 register), the CPU should service the received frame using the following procedure:

1. Read the Control and Status word (optional: needed only if a mask was used for IDE and RTR bits)
2. Read the ID field (optional: needed only if a mask was used)
3. Read the Data field
4. Read the CAN\_RXFIR register (optional)
5. Clear the Frames Available in Legacy Rx FIFO interrupt by writing 1 to CAN\_IFLAG1[BUF5I] bit (mandatory: releases the MB and allows the CPU to read the next Rx FIFO entry)

When CAN\_MCR[DMA] is asserted, upon receiving a frame in Legacy FIFO, CAN\_IFLAG1[BUF5I] generates a DMA request and does not generate a CPU interrupt (see [Legacy Rx FIFO under DMA Operation](#)). The CAN\_IMASK1 bits in Legacy Rx FIFO region are not used.

The DMA controller must service the received frame using the following procedure:

1. Read the Control and Status word (read 0x80 address, optional)
2. Read the ID field (read 0x84 address, optional)

3. Read all Data Bytes (start read at 0x88 address, optional)
4. Read the last Data Bytes (read 0x8C address is mandatory)

#### 44.4.4 Matching process

The matching process scans the MB memory looking for Rx MBs programmed with the same ID as the one received from the CAN bus. If the Legacy Rx or Enhanced Rx FIFO is enabled, the priority of scanning can be selected between Mailboxes and FIFO filters. The matching starts from the lowest number Message Buffer toward the higher ones. If no match is found within the first structure then the other is scanned subsequently. In the event that the FIFO is full, the matching algorithm always looks for a matching MB outside the FIFO region.

As the frame is being received, it is stored in a hidden auxiliary MB called Rx Serial Message Buffer (Rx SMB).

The matching process start point depends on the following conditions:

- If the received frame is a remote frame, the start point is the CRC field of the frame
- If the received frame is a data frame with DLC field equal to zero, the start point is the CRC field of the frame
- If the received frame is a data frame with DLC field different than zero, the start point is the DATA field of the frame

If a matching ID is found in the FIFO table or in one of the Mailboxes, the contents of the Rx SMB are transferred to the FIFO or to the matched Mailbox by the move-in process. If any CAN protocol error is detected then no match results are transferred to the FIFO or to the matched Mailbox at the end of reception.

The matching process scans all matching elements of both Rx FIFO (if enabled) and the active Rx Mailboxes (CODE is EMPTY, FULL, OVERRUN or RANSWER) in search of a successful comparison with the matching elements of the Rx SMB that is receiving the frame on the CAN bus. The Rx SMB has the same structure of a Mailbox. The reception structures (Rx FIFO or Mailboxes) associated with the matching elements that had a successful comparison are the *matched structures*. The *matching winner* is selected at the end of the scan among those matched structures and depends on conditions described ahead. See the following table.

Table 44-6. Matching architecture

Structure	SMB[RTR]	CTRL2[RRS]	CTRL2[EAC EN]	MB[IDE]	MB[RTR]	MB[ID <sup>1</sup> ]	MB[CODE]
Mailbox	0	-	0	cmp <sup>2</sup>	no_cmp <sup>3</sup>	cmp_msk <sup>4</sup>	EMPTY or FULL or OVERRUN
Mailbox	0	-	1	cmp_msk	cmp_msk	cmp_msk	EMPTY or FULL or OVERRUN
Mailbox	1	0	-	cmp	no_cmp	cmp	RANSWER
Mailbox	1	1	0	cmp	no_cmp	cmp_msk	EMPTY or FULL or OVERRUN
Mailbox	1	1	1	cmp_msk	cmp_msk	cmp_msk	EMPTY or FULL or OVERRUN
Legacy Rx FIFO <sup>5</sup>	-	-	-	cmp_msk	cmp_msk	cmp_msk	-

1. For Mailbox structure, If SMB[IDE] is asserted, the ID is 29 bits (ID Standard + ID Extended). If SMB[IDE] is negated, the ID is only 11 bits (ID Standard). For Legacy Rx FIFO structure, the ID depends on IDAM.
2. cmp: Compares the Rx SMB contents with the MB contents regardless the masks.
3. no\_cmp: The Rx SMB contents are not compared with the MB contents.
4. cmp\_msk: Compares the Rx SMB contents with MB contents taking into account the masks.
5. SMB[IDE] and SMB[RTR] are not taken into account when IDAM is type C.

### NOTE

For Enhanced Rx FIFO, see [Enhanced Rx FIFO matching process](#).

A reception structure is *free-to-receive* when any of the following conditions is satisfied:

- The CODE field of the Mailbox is EMPTY
- The CODE field of the Mailbox is either FULL or OVERRUN and it has already been serviced (the C/S word was read by the CPU and unlocked as described in [Mailbox lock mechanism](#))
- The CODE field of the Mailbox is either FULL or OVERRUN and an inactivation (see [Mailbox inactivation](#)) is performed
- The Legacy Rx FIFO or Enhanced Rx FIFO is not full

The scan order for Mailboxes and Legacy Rx FIFO is from the matching element with lowest number to the higher ones.

The matching winner search for Mailboxes is affected by the CAN\_MCR[IRMQ] bit. If it is negated, the matching winner is the first matched Mailbox regardless if it is free-to-receive or not. If it is asserted, the matching winner is selected according to the priority below:

1. the first free-to-receive matched Mailbox;

## Functional description

2. the last non free-to-receive matched Mailbox.

It is possible to select the priority of scan between Mailboxes and Legacy Rx FIFO or Enhanced Rx FIFO by the CAN\_CTRL2[MRP] bit.

If the selected priority is Rx FIFO first:

- If the Rx FIFO is a matched structure and is free-to-receive, then the Rx FIFO is the matching winner regardless of the scan for Mailboxes
- Otherwise (the Rx FIFO is not a matched structure or is not free-to-receive), then the matching winner is searched among Mailboxes as described above

If the selected priority is Mailboxes first:

- If a free-to-receive matched Mailbox is found, it is the matching winner regardless of the scan for Rx FIFO
- If no matched Mailbox is found, then the matching winner is searched in the scan for the Rx FIFO
- If both conditions above are not satisfied and a non free-to-receive matched Mailbox is found, then the matching winner determination is conditioned by the CAN\_MCR[IRMQ] bit:
  - If CAN\_MCR[IRMQ] bit is negated, the matching winner is the first matched Mailbox
  - If CAN\_MCR[IRMQ] bit is asserted, the matching winner is the Rx FIFO if it is a free-to-receive matched structure; otherwise, the matching winner is the last non free-to-receive matched Mailbox

See the following table for a summary of matching possibilities.

**Table 44-7. Matching possibilities and resulting reception structures**

RFEN or ERFEN	IRMQ	MRP	Matched in MB	Matched in FIFO	Reception structure	Description
<b>No FIFO, only MB, match is always MB first</b>						
0	0	X <sup>1</sup>	None <sup>2</sup>	- <sup>3</sup>	None	Frame lost by no match
0	0	X	Free <sup>4</sup>	-	FirstMB	
0	1	X	None	-	None	Frame lost by no match
0	1	X	Free	-	FirstMb	
0	1	X	NotFree	-	LastMB	Overrun
<b>FIFO enabled, no match in FIFO is as if FIFO does not exist</b>						
1	0	X	None	None <sup>5</sup>	None	Frame lost by no match
1	0	X	Free	None	FirstMB	

*Table continues on the next page...*

**Table 44-7. Matching possibilities and resulting reception structures (continued)**

RFEN or ERFEN	IRMQ	MRP	Matched in MB	Matched in FIFO	Reception structure	Description
1	1	X	None	None	None	Frame lost by no match
1	1	X	Free	None	FirstMb	
1	1	X	NotFree	None	LastMB	Overrun
<b>FIFO enabled, Queue disabled</b>						
1	0	0	X	NotFull <sup>6</sup>	FIFO	
1	0	0	None	Full <sup>7</sup>	None	Frame lost by FIFO full (FIFO Overflow)
1	0	0	Free	Full	FirstMB	
1	0	0	NotFree	Full	FirstMB	
1	0	1	None	NotFull	FIFO	
1	0	1	None	Full	None	Frame lost by FIFO full (FIFO Overflow)
1	0	1	Free	X	FirstMB	
1	0	1	NotFree	X	FirtsMb	Overrun
<b>FIFO enabled, Queue enabled</b>						
1	1	0	X	NotFull	FIFO	
1	1	0	None	Full	None	Frame lost by FIFO full (FIFO Overflow)
1	1	0	Free	Full	FirstMB	
1	1	0	NotFree	Full	LastMb	Overrun
1	1	1	None	NotFull	FIFO	
1	1	1	Free	X	FirstMB	
1	1	1	NotFree	NotFull	FIFO	
1	1	1	NotFree	Full	LastMb	Overrun

1. This is a don't care condition.
2. Matched in MB "None" means that the frame has not matched any MB (free-to-receive or non-free-to-receive).
3. This is a forbidden condition.
4. Matched in MB "Free" means that the frame matched at least one MB free-to-receive regardless of whether it has matched MBs non-free-to-receive.
5. Matched in FIFO "None" means that the frame has not matched any filter in FIFO. It is as if the FIFO didn't exist (CAN\_CTRL2[RFEN]=0 and CAN\_ERFCR[ERFEN]=0).
6. Matched in FIFO "NotFull" means that the frame has matched a FIFO filter and has empty slots to receive it.
7. Matched in FIFO "Full" means that the frame has matched a FIFO filter but couldn't store it because it has no empty slots to receive it.

If a non-safe Mailbox inactivation (see [Mailbox inactivation](#)) occurs during matching process and the Mailbox inactivated is the temporary matching winner, then the temporary matching winner is invalidated. The matching elements scan is not stopped nor

restarted, it continues normally. The consequence is that the current matching process works as if the matching elements compared before the inactivation did not exist, therefore a message may be lost.

Suppose, for example, that the FIFO is disabled, IRMQ is enabled and there are two MBs with the same ID, and FlexCAN starts receiving messages with that ID. Let us say that these MBs are the second and the fifth in the array. When the first message arrives, the matching algorithm finds the first match in MB number 2. The code of this MB is EMPTY, so the message is stored there. When the second message arrives, the matching algorithm finds MB number 2 again, but it is not "free-to-receive", so it keeps looking, finds MB number 5 and stores the message there. If yet another message with the same ID arrives, the matching algorithm finds out that there are no matching MBs that are "free-to-receive", so it decides to overwrite the last matched MB, which is number 5. In doing so, it sets the CODE field of the MB to indicate OVERRUN.

The ability to match the same ID in more than one MB can be exploited to implement a reception queue (in addition to the full featured FIFO) to allow more time for the CPU to service the MBs. By programming more than one MB with the same ID, received messages are queued into the MBs. The CPU can examine the Time Stamp field of the MBs to determine the order in which the messages arrived.

Matching to a range of IDs is possible by using ID Acceptance Masks. FlexCAN supports individual masking per MB. See the description of the Rx Individual Mask Registers (CAN\_RXIMRx). During the matching algorithm, if a mask bit is asserted, then the corresponding ID bit is compared. If the mask bit is negated, the corresponding ID bit is a "don't care". Note that the Individual Mask Registers are implemented in RAM, so they are not initialized out of reset. Also, they can only be programmed while the module is in Freeze mode; otherwise, they are blocked by hardware.

FlexCAN also supports an alternate masking scheme with only four mask registers (CAN\_RXFGMASK, CAN\_RXMGMASK, CAN\_RX14MASK and CAN\_RX15MASK) for backwards compatibility with legacy applications. This alternate masking scheme is enabled when the IRMQ bit in the CAN\_MCR Register is negated.

#### **44.4.5 Move process**

There are two types of move process: move-in and move-out.

### 44.4.5.1 Move-in

The move-in process is the copy of a message received by an Rx SMB to a Rx Mailbox or FIFO that has matched it. If the move destination is the Legacy Rx FIFO, attributes of the message are also copied to the CAN\_RXFIR FIFO. Each Rx SMB has its own move-in process, but only one is performed at a given time as described ahead. The move-in starts only when the message held by the Rx SMB has a corresponding matching winner (see [Matching process](#)) and all of the following conditions are true:

- The CAN bus has reached or let past either:
  - The second bit of Intermission field next to the frame that carried the message that is in the Rx SMB
  - The first bit of an overload frame next to the frame that carried the message that is in the Rx SMB
- There is no ongoing matching process
- The destination Mailbox is not locked by the CPU
- There is no ongoing move-in process from another Rx SMB. If more than one move-in processes are to be started at the same time both are performed and the newest substitutes the oldest.

The term *pending move-in* is used throughout the documentation and stands for a move-to-be that still does not satisfy all of the aforementioned conditions.

The move-in is cancelled and the Rx SMB is able to receive another message if any of the following conditions is satisfied:

- The destination Mailbox is inactivated after the CAN bus has reached the first bit of Intermission field next to the frame that carried the message and its matching process has finished
- There is a previous pending move-in to the same destination Mailbox
- The Rx SMB is receiving a frame transmitted by the FlexCAN itself and the self-reception is disabled (CAN\_MCR[SRXDIS] bit is asserted)
- Any CAN protocol error is detected

Note that the pending move-in is not cancelled if the module enters Freeze or Low-Power mode. It only stays on hold waiting for exiting Freeze and Low-Power mode and to be unlocked. If an MB is unlocked during Freeze mode, the move-in happens immediately.

The move-in process is the execution by the FlexCAN of the following steps:

1. Push IDHIT into the RXFIR FIFO if the message is destined to the Legacy Rx FIFO.
2. Read all data words from the Rx SMB in accordance to the selected payload size for the Rx storage element.
3. Write all data words to the Rx Mailbox in accordance to the selected payload size for the Rx storage element. If the data size of the storage element is smaller than the

original payload size described in the message's DLC field, the payload is truncated and the high order bytes that do not fit the destination size are lost.

4. Read the Control/Status and ID words from the Rx SMB.
5. Write Control/Status and ID words to the Rx Mailbox, and update the CODE field.

The move-in process is not atomic, in such a way that it is immediately cancelled by the inactivation of the destination Mailbox (see [Mailbox inactivation](#)) and in this case the Mailbox may be left partially updated, thus incoherent. The exception is if the move-in destination is a Legacy or Enhanced Rx FIFO Message Buffer, then the process cannot be cancelled.

The BUSY Bit (least significant bit of the CODE field) of the destination Message Buffer is asserted while the move-in is being performed to alert the CPU that the Message Buffer content is temporarily incoherent.

#### **44.4.5.2 Move-out**

The move-out process is the copy of the content from a Tx Mailbox to the Tx SMB when a message for transmission is available (see Section "Arbitration process"). The move-out occurs in the following conditions:

- The first bit of Intermission field
- During Bus Off state when TX Error Counter is in the 124 to 128 range
- During Bus Idle state
- During Wait For Bus Idle state

The move-out process is not atomic. Only the CPU has priority to access the memory concurrently out of Bus Idle state. In Bus Idle, the move-out has the lowest priority to the concurrent memory accesses.

#### **44.4.6 Data coherence**

In order to maintain data coherency and FlexCAN proper operation, the CPU must obey the rules described in [Transmit process](#) and [Receive process](#).

##### **44.4.6.1 Transmission abort mechanism**

The abort mechanism provides a safe way to request the abortion of a pending transmission. A feedback mechanism is provided to inform the CPU if the transmission was aborted or if the frame could not be aborted and was transmitted instead.

Two primary conditions must be fulfilled in order to abort a transmission:

- CAN\_MCR[AEN] bit must be asserted
- The first CPU action must be the writing of abort code (0b1001) into the CODE field of the Control and Status word.

Active MBs configured for transmission must be aborted first before they can be updated. If the abort code is written to a Mailbox that is currently being transmitted or to a Mailbox that was already loaded into the Tx SMB for transmission, the write operation is blocked and the transmission is not disturbed. However, the abort request is captured and kept pending until one of the following conditions is satisfied:

- The module loses the bus arbitration
- There is an error during the transmission
- The module is put into Freeze mode
- The module enters the BusOff state
- There is an overload frame

If none of the conditions above are reached, the MB is transmitted correctly, the interrupt flag is set in the IFLAG register, and an interrupt to the CPU is generated (if enabled). The abort request is automatically cleared when the interrupt flag is set. On the other hand, if one of the above conditions is reached, the frame is not transmitted; therefore, the abort code is written into the CODE field, the interrupt flag is set in the IFLAG, and an interrupt is (optionally) generated to the CPU.

If the CPU writes the abort code before the transmission begins internally, then the write operation is not blocked; therefore, the MB is updated and the interrupt flag is set. In this way the CPU just needs to read the abort code to make sure the active MB was *safely inactivated*. Although the AEN bit is asserted and the CPU wrote the abort code, in this case the MB is inactivated and not aborted, because the transmission did not start yet. One Mailbox is only aborted when the abort request is captured and kept pending until one of the previous conditions are satisfied.

#### 44.4.6.2 Mailbox inactivation

Inactivation is a mechanism provided to protect the Mailbox against updates by the FlexCAN internal processes, thus allowing the CPU to rely on Mailbox data coherence after having updated it, even in Normal mode.

Inactivation of transmission Mailboxes must be performed just when MCR[AEN] bit is deasserted.

If a Mailbox is inactivated, it participates in neither the arbitration process nor the matching process until it is reactivated. See [Transmit process](#) and [Receive process](#) for more detailed instructions on how to inactivate and reactivate a Mailbox.

To inactivate a Mailbox, the CPU must update its CODE field to INACTIVE (either 0b0000 or 0b1000).

Because the user is not able to synchronize the CODE field update with the FlexCAN internal processes, an inactivation can have the following consequences:

- A frame in the bus that matches the filtering of the inactivated Rx Mailbox may be lost without notice, even if there are other Mailboxes with the same filter
- A frame containing the message within the inactivated Tx Mailbox may be transmitted without setting the respective IFLAG

In order to perform a *safe inactivation* and avoid the above consequences for Tx Mailboxes, the CPU must use the Transmission Abort mechanism (see [Transmission abort mechanism](#)).

The inactivation automatically unlocks the Mailbox (see [Mailbox lock mechanism](#)).

### NOTE

Message Buffers that are part of the Legacy Rx FIFO or Enhanced Rx FIFO cannot be inactivated. There is no write protection on the Legacy FIFO region by FlexCAN. CPU must maintain data coherency in the Legacy FIFO region when RFEN is asserted.

### 44.4.6.3 Mailbox lock mechanism

Other than Mailbox inactivation, FlexCAN has another data coherence mechanism for the receive process. When the CPU reads the Control and Status word of an Rx MB with codes FULL or OVERRUN, FlexCAN assumes that the CPU wants to read the whole MB in an atomic operation, and therefore it sets an internal lock flag for that MB. The lock is released when the CPU reads the Free Running Timer (global unlock operation), or when it reads the Control and Status word of another MB regardless of its code. A CPU write into the C/S word also unlocks the MB, but this procedure is not recommended for normal unlock use because it cancels a pending-move and potentially may lose a received message. The MB locking prevents a new frame from being written into the MB while the CPU is reading it.

### NOTE

The locking mechanism applies only to Rx MBs that are not part of the Legacy Rx FIFO and have a code different than

INACTIVE (0b0000) or EMPTY<sup>1</sup> (0b0100). Also, Tx MBs can not be locked.

Suppose, for example, that the Legacy Rx FIFO is disabled and the second and the fifth MBs of the array are programmed with the same ID, and FlexCAN has already received and stored messages into these two MBs. Suppose now that the CPU decides to read MB number 5 and at the same time another message with the same ID is arriving. When the CPU reads the Control and Status word of MB number 5, this MB is locked. The new message arrives and the matching algorithm finds out that there are no "free-to-receive" MBs, so it decides to override MB number 5. However, this MB is locked, so the new message can not be written there. It will remain in the Rx SMB waiting for the MB to be unlocked, and only then will be written to the MB.

If the MB is not unlocked in time and yet another new message with the same ID arrives, then the new message overwrites the one on the Rx SMB and there will be no indication of lost messages either in the CODE field of the MB or in the Error and Status Register.

While the message is being moved-in from the Rx SMB to the MB, the BUSY bit on the CODE field is asserted. If the CPU reads the Control and Status word and finds out that the BUSY bit is set, it should defer accessing the MB until the BUSY bit is negated.

### Note

If the BUSY bit is asserted or if the MB is empty, then reading the Control and Status word does not lock the MB.

Inactivation takes precedence over locking. If the CPU inactivates a locked Rx MB, then its lock status is negated and the MB is marked as invalid for the current matching round. Any pending message on the Rx SMB will not be transferred anymore to the MB. An MB is unlocked when the CPU reads the Free Running Timer Register (see Section "Free Running Timer Register (CAN\_TIMER)"), or the C/S word of another MB.

Lock and unlock mechanisms have the same functionality in both Normal and Freeze modes.

An unlock during Normal or Freeze mode results in the move-in of the pending message. However, the move-in is postponed if an unlock occurs during a low power mode (see [Modes of operation](#)), and it takes place only when the module resumes to Normal or Freeze modes.

---

1. In previous FlexCAN versions, reading the C/S word locked the MB even if it was EMPTY. This behavior is maintained when the IRMQ bit is negated.

## 44.4.7 Enhanced Rx FIFO

FlexCAN supports an enhanced Rx FIFO engine which can store up to 32 CAN FD messages. The region 0x2000 – 0x204F contains the output of the FIFO which should be read by the CPU. The enhanced Rx FIFO is enabled by setting EFRCCR[ERFEN]. Although FlexCAN has two FIFO options, Legacy Rx FIFO and Enhanced Rx FIFO, they cannot be enabled at the same time. Refer to [Legacy Rx FIFO](#) to find detailed information about Legacy Rx FIFO.

The enhanced Rx FIFO has a watermark which is configured by setting EFRCCR[ERFWM]. If EFRCCR[ERFWM] is set, the CPU is notified only if a minimum number of messages is stored in the FIFO. When the number of stored messages is greater than the value in EFRCCR[ERFWM], ERFSR[ERFWMI] is set by the hardware. Optionally, an interrupt or a DMA transfer can be triggered if MCR[DMA] or ERFIER[ERFWMIIE] are set, respectively.

For the Enhanced Rx FIFO to receive, the CPU must execute the configuration procedure below. The same procedure must be done if the CPU needs to change any of the configuration of the Enhanced RX FIFO.

1. Enter Freeze mode.
2. Enable Enhanced Rx FIFO by setting EFRCCR[ERFEN], if it is not already enabled.<sup>3</sup>
3. Write one to ERFSR[ERFCLR] to reset Enhanced Rx FIFO engine.
4. Clear ERFSR[ERFUFW], ERFSR[ERFOVF], ERFSR[ERFWMI], and ERFSR[ERFDA], if they are set.
5. Write EFRCCR[NFE] to configure the total number of enhanced Rx FIFO filter elements to be used in Enhanced Rx FIFO reception.
6. Write EFRCCR[NEXIF] to configure the number of extended ID and standard ID filter elements to be used in Enhanced Rx FIFO reception.<sup>4</sup>
7. Configure the Enhanced Rx FIFO watermark by writing EFRCCR[ERFWM].
8. If interrupts will be used, set the interrupt enables in the ERIER register.
9. If DMA will be used, set MCR[DMA] to enable DMA operation and write EFRCCR[DMALW] to configure the number of words to be transfer for each Enhanced Rx FIFO data element.
10. Configure the filter elements by writing in the ERFFEL $n$  registers.<sup>5</sup>
11. Leave Freeze mode.

3. MCR[RFEN] must be cleared so that Enhanced Rx FIFO is enabled.

4.  $NEXIF \leq NFE + 1$ .

5. ERFFEL $n$  registers are implemented in RAM; thus they must be explicitly initialized prior to any reception.

There are two types of Enhanced Rx FIFO filter elements that can be stored in  $ERFFEL_n$  registers: extended-ID filter element and standard-ID filter element. Each extended-ID filter element is stored in two  $ERFFEL_n$  registers while each standard-ID filter element is stored in one  $ERFFEL_n$  register. The total number of Enhanced RX FIFO filter elements is defined by  $ERFCR[NFE]$ .

In addition, the filter memory space can be split into two regions: one for extended-ID filter elements and another for standard-ID filter elements, according to  $ERFCR[NEXIF]$ . The figure below shows how the Enhanced Rx filter elements are defined. Detailed information about the Enhanced Rx FIFO matching process and filter element formats can be found in [Enhanced Rx FIFO matching process](#).

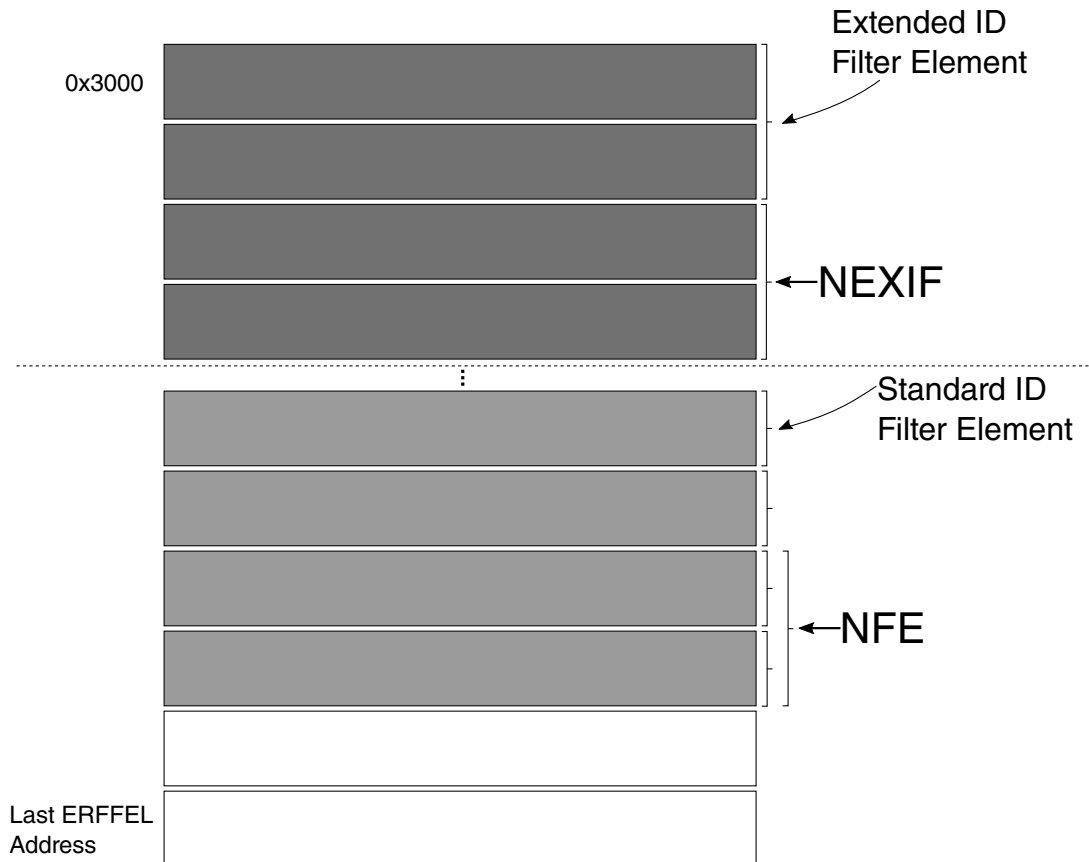

Figure 44-2. Number of enhanced Rx FIFO filter elements

#### 44.4.7.1 Enhanced Rx FIFO matching process

When  $CAN\_ERFCR[ERFEN]$  is enabled, FlexCAN scans the  $ERFFEL_n$  memory region. If at least one filter element satisfies the matching criteria, then the CAN message content is transferred to the enhanced RX FIFO memory.

## Functional description

Each  $ERFFEL_n$  register can store one standard filter element. The matching criteria are defined by  $ERFFEL_n[FSCH]$  in this way:

- If  $FSCH = b00$ , the filter scheme is based on mask and filter. A CAN message matches a standard ID filter element only if these criteria are reached:
  - a. CAN message is base frame format ( $IDE = 0$ )
  - b. ( $ID[n] = STD\ ID\ filter\ [n]$ ) or ( $STD\ ID\ Mask[n] = 0$ ) for each bit  $n$  from 0 to 10
  - c. ( $RTR = RTR\ Filter$ ) or ( $RTR\ MASK = 0$ )

In this explanation, RTR and ID are the Remote Transmit Request field and the ID from a CAN message, respectively.

If  $FSCH = b00$ , the filters and masks are defined as shown in this table.

**Table 44-8. Standard ID filter element with filter + mask scheme (FSCH = b00)**

31	30	29	28	27	26											16	15			12	11	10										0
FSCH=b00		Reserved		RTR filter	STD ID filter												Reserved		RTR mask	STD ID mask												

- If  $FSCH = b01$ , the filter scheme is based on range. A CAN message matches a standard ID filter element only if these criteria are reached:
  - a. CAN message is base frame format ( $IDE = 0$ )
  - b.  $ID \geq STD\ ID\ Filter1$
  - c.  $ID \leq STD\ ID\ Filter2$
  - d. ( $RTR = RTR\ filter$ ) or ( $RTR\ MASK = 0$ )

RTR and ID are the Remote Transmit Request bit and ID from a CAN message, respectively. If  $FSCH = b01$ , the filters and mask are defined as shown in this table.

**Table 44-9. Standard ID filter element with range scheme (FSCH = b01)**

31	30	29	28	27	26											16	15			12	11	10										0
FSCH=b01		Reserved		RTR filter	STD ID Filter2												Reserved		RTR mask	STD ID Filter1												

- If  $FSCH = b10$ , the filter scheme is based on two filters without masks. A CAN message matches a standard ID filter element only if these criteria are reached:
  - a. CAN message is base frame format ( $IDE = 0$ )
  - b. ( $ID[n] = STD\ ID\ Filter1[n]$ ) or ( $ID[n] = STD\ ID\ Filter2[n]$ ) for each bit  $n$  from 0 to 10
  - c. ( $RTR = RTR\ Filter1$ ) or ( $RTR = RTR\ Filter2$ )

RTR and ID are the Remote Transmit Request bit and ID from a CAN message, respectively. If  $FSCH = b10$ , the filters are defined as shown in this table.

**Table 44-10. Standard ID filter element with 2-filter scheme (FSCH = b10)**

31	30	29	28	27	26											16	15			12	11	10										0
FSCH=b10		Reserved		RTR Filter2	STD ID Filter2												Reserved		RTR Filter1	STD ID Filter1												

Each pair of  $ERFFEL_n$  registers can store one extended filter element. The matching criteria are defined by  $ERFFEL_n[FSCH]$  in this way:

- If  $FSCH = b00$ , the filter scheme is based on mask and filter. A CAN message matches an extended ID filter element only if these criteria are reached:
  - a. CAN message is extended frame format ( $IDE = 1$ )
  - b.  $(ID[n] = EXT\ ID\ filter[n])$  or  $(EXT\ ID\ Mask[n] = 0)$  for each bit  $n$  from 0 to 28
  - c.  $(RTR = RTR\ Filter)$  or  $(RTR\ MASK = 0)$

If  $FSCH = b00$ , the filters and masks are defined as shown in this table.

**Table 44-11. Extended ID filter element with filter + mask scheme (FSCH = b00)**

31	30	29	28																															0
FSCH		RTR filter		EXT ID filter																														
Reserved		RTR mask		EXT ID mask																														

- If  $FSCH = b01$ , the filter scheme is based on range. A CAN message matches an extended ID filter element only if the following criteria are reached:
  - a. CAN message is extended frame format ( $IDE = 1$ )
  - b.  $ID \geq EXT\ ID\ Filter1$
  - c.  $ID \leq EXT\ ID\ Filter2$
  - d.  $(RTR = RTR\ Filter)$  or  $(RTR\ MASK = 0)$

If  $FSCH = b01$ , the filters and masks are defined as shown in this table.

**Table 44-12. Extended ID filter element with range scheme (FSCH = b01)**

31	30	29	28																															0
FSCH		RTR filter		EXT ID Filter2																														
Reserved		RTR mask		EXT ID filter 1																														

- If  $FSCH = b10$ , the filter scheme is based on two filters without masks. A CAN message matches an extended ID filter element only if these criteria are reached:
  - a. CAN message is extended frame format ( $IDE = 1$ )
  - b.  $(ID[n] = EXT\ ID\ Filter1[n])$  or  $(ID[n] = EXT\ ID\ Filter2[n])$  for each bit  $n$  from 0 to 28

c. (RTR = RTR Filter1) or (RTR = RTR Filter2)

If FSCH = b10, the filters and masks are defined as shown in this table.

**Table 44-13. Extended ID filter element with 2-filter scheme (FSCH = b10)**

31	30	29	28																0
FSCH		RTR Filter2	EXT ID Filter2																
Reserved		RTR Filter1	EXT ID filter 1																

#### 44.4.7.2 Enhanced Rx FIFO under DMA operation

The DMA feature is enabled by asserting both CAN\_ERF[ERFEN] and CAN\_MCR[DMA]. The DMA controller can read the received message by reading a Message Buffer structure at the Enhanced FIFO output port at the address range defined in [Enhanced Rx FIFO structure](#).

The CPU should not access the Enhanced FIFO output port address range during DMA operation, so that the FIFO engine operates properly. Before enabling CAN\_MCR[DMA], the CPU must service Enhanced Rx FIFO status bits. Otherwise, these bits may show that the FIFO has data to be serviced, and mistakenly generate a DMA request. Before disabling CAN\_MCR[DMA], the CPU must first clear the ERFUFW, ERFOVF, ERMWMI and ERFDA fields in the CAN\_ERFSR register, and then clear the Enhanced RX FIFO engine by writing one to CAN\_ERFSR[ERFCLR].

CAN\_ERFSR[ERFDA] is set by the hardware when there is at least one frame available to be read from the Enhanced Rx FIFO, and CAN\_ERFSR[ERFWMI] is set by the hardware when the number of frames stored in the FIFO is greater than the watermark defined by CAN\_ERFCR[ERFWM]. A DMA request is generated when CAN\_ERFSR[ERFWMI] is set. Upon receiving the request, the DMA controller can read the message in the Enhanced Rx FIFO output. The DMA controller must perform the number of read loops in the FIFO output defined by CAN\_ERFCR[ERFWM]. Also, each message reading process must end by the address defined in CAN\_ERFCR[DMALW].

Each time one message is read from FIFO by the DMA controller, CAN\_ERFSR[ERFDA] is cleared by FlexCAN and set again if there is at least one message stored in the FIFO. Moreover, CAN\_ERFSR[ERFWMI] is cleared by the hardware when the messages are read in the FIFO output, and set again if the number of messages in the FIFO is greater than the value defined by ERFCR[ERFWM].

### 44.4.7.3 Enhanced Rx FIFO clear operation

When ERFEN bit in CAN\_ERFCR register is set, the CPU can clear the Enhanced Rx FIFO by writing one into the ERFCLR bit in CAN\_ERFSR register. The clear operation resets the internal FIFO pointers although the FIFO content stored in RAM is not changed. This operation can only be performed in Freeze Mode and is blocked by hardware in other modes. This operation does not clear the ERFUFW, ERFOVF, ERFDA and ERFWMI bits in CAN\_ERFSR register, consequently the CPU must service all these bits before execute the clear FIFO task.

### 44.4.8 Legacy Rx FIFO

The Legacy Rx FIFO is receive-only and is enabled by asserting the CAN\_MCR[RFEN] bit. The reset value of this bit is zero to maintain software backward compatibility with previous versions of the module that did not have the Legacy FIFO feature.

#### CAUTION

Legacy Rx FIFO must not be enabled when CAN FD feature is enabled.

The Legacy FIFO is 6-message deep. The memory region occupied by the Legacy FIFO structure (both Message Buffers and Legacy FIFO engine) is described in [Legacy Rx FIFO structure](#). The CPU can read the received messages sequentially, in the order they were received, by repeatedly reading a Message Buffer structure at the output of the Legacy FIFO.

The CAN\_IFLAG1[BUF5I] (Frames available in Legacy Rx FIFO) is asserted when there is at least one frame available to be read from the Legacy FIFO. An interrupt is generated if it is enabled by the corresponding mask bit. Upon receiving the interrupt, the CPU can read the message (accessing the output of the Legacy FIFO as a Message Buffer) and the CAN\_RXFIR register and then clear the interrupt. If there are more messages in the Legacy FIFO the act of clearing the interrupt updates the output of the Legacy FIFO with the next message and update the CAN\_RXFIR with the attributes of that message, reissuing the interrupt to the CPU. Otherwise, the flag remains negated. The output of the Legacy FIFO is only valid whilst the CAN\_IFLAG1[BUF5I] is asserted.

The CAN\_IFLAG1[BUF6I] (Legacy Rx FIFO Warning) is asserted when the number of unread messages within the Legacy Rx FIFO is increased to 5 from 4 due to the reception of a new one, meaning that the Legacy Rx FIFO is almost full. The flag remains asserted until the CPU clears it.

## Functional description

The CAN\_IFLAG1[BUF7I] (Legacy Rx FIFO Overflow) is asserted when an incoming message was lost because the Legacy Rx FIFO is full. Note that the flag will not be asserted when the Legacy Rx FIFO is full and the message was captured by a Mailbox. The flag remains asserted until the CPU clears it.

Clearing one of those three flags does not affect the state of the other two.

An interrupt is generated if an IFLAG bit is asserted and the corresponding mask bit is asserted too.

A powerful filtering scheme is provided to accept only frames intended for the target application, reducing the interrupt servicing work load. The filtering criteria is specified by programming a table of up to 128 32-bit registers, according to CAN\_CTRL2[RFFN] setting, that can be configured to one of the following formats (see also [Legacy Rx FIFO structure](#)):

- Format A: 128 IDAFs (extended or standard IDs including IDE and RTR)
- Format B: 256 IDAFs (standard IDs or extended 14-bit ID slices including IDE and RTR)
- Format C: 512 IDAFs (standard or extended 8-bit ID slices)

### Note

A chosen format is applied to all entries of the filter table. It is not possible to mix formats within the table.

Every frame available in the Legacy Rx FIFO has a corresponding IDHIT (Identifier Acceptance Filter Hit Indicator) that can read in the IDHIT field from C/S word, as shown in the Legacy Rx FIFO Structure description. Another way the CPU can obtain this information is by accessing the CAN\_RXFIR register. The CAN\_RXFIR[IDHIT] field refers to the message at the output of the Legacy FIFO and is valid while the CAN\_IFLAG1[BUF5I] flag is asserted. The CAN\_RXFIR register must be read only before clearing the flag, which guarantees that the information refers to the correct frame within the Legacy FIFO.

Up to 32 elements of the filter table are individually affected by the Individual Mask Registers (CAN\_RXIMRx), according to the setting of CAN\_CTRL2[RFFN], allowing very powerful filtering criteria to be defined. If the CAN\_MCR[IRMQ] bit is negated, then the Legacy Rx FIFO filter table is affected by CAN\_RXFGMASK.

### NOTE

For more information about the difference between FD and non-FD regarding this feature, see [Table 44-2](#).

### 44.4.8.1 Legacy Rx FIFO under DMA Operation

The receive-only Legacy FIFO can support DMA, this feature is enabled by asserting both the CAN\_MCR[RFEN] and CAN\_MCR[DMA] bits. The reset value of CAN\_MCR[DMA] bit is zero to maintain backward compatibility with previous versions of the module that did not have the DMA feature.

The DMA controller can read the received message by reading a Message Buffer structure at the Legacy FIFO output port at the 0x80-0x8C address range.

When CAN\_MCR[DMA] is asserted the CPU must not access the Legacy FIFO output port address range. Before enabling the CAN\_MCR[DMA], the CPU must service the IFLAGs asserted in the Legacy Rx FIFO region. Otherwise, these IFLAGs may show that the FIFO has data to be serviced, and mistakenly generate a DMA request. Before disabling the CAN\_MCR[DMA], the CPU must perform a clear Legacy FIFO operation.

The CAN\_IFLAG1[BUF5I] (Frames available in Legacy Rx FIFO) is asserted when there is at least one frame available to be read from the FIFO, consequently a DMA request is generated simultaneously. Upon receiving the request, the DMA controller can read the message (accessing the output of the Legacy FIFO as a Message Buffer). The DMA reading process must end by reading address 0x8C, which clears the CAN\_IFLAG1[BUF5I] and updates both the FIFO output with the next message (if FIFO is not empty) and the CAN\_RXFIR register with the attributes of the new message. If there are more messages stored in the FIFO, the CAN\_IFLAG1[BUF5I] will be re-asserted and another DMA request is issued. Otherwise, the flag remains negated.

#### NOTE

CAN\_RXFIR register contents cannot be read after DMA completes the Legacy FIFO read. The IDHIT information is also available in the C/S word at address 0x080 (see [Legacy Rx FIFO structure](#)).

The CAN\_IFLAG1[BUF6I] and CAN\_IFLAG1[BUF7I] are not used when the DMA feature is enabled.

When FlexCAN is working with DMA, the CPU does not receive any Legacy Rx FIFO interruption and must not clear the related IFLAGs. In addition, the related IMASKs are not used to mask the generation of DMA requests.

#### NOTE

For more information about the difference between FD and non-FD regarding this feature, see [Table 44-2](#).

### 44.4.8.2 Clear Legacy FIFO Operation

When CAN\_MCR[RFEN] is asserted, the clear Legacy FIFO operation is a feature used to empty Legacy FIFO contents. With CAN\_MCR[RFEN] asserted the Clear FIFO occurs when the CPU writes 1 in CAN\_IFLAG1[BUF0I]. This operation can only be performed in Freeze Mode and is blocked by hardware in other modes. This operation does not clear the FIFO IFLAGs, consequently the CPU must service all FIFO IFLAGs before execute the clear FIFO task.

When Legacy Rx FIFO is working with DMA, the clear FIFO operation clears the CAN\_IFLAG1[BUF5I] and the DMA request is canceled.

#### CAUTION

*Clear Legacy FIFO operation does not clear IFLAGs, except when CAN\_MCR[DMA] is asserted, in this case only the CAN\_IFLAG1[BUF5I] is cleared.*

### 44.4.9 CAN protocol related features

This section describes the CAN protocol related features.

#### 44.4.9.1 CAN FD ISO compliance

The CAN FD protocol has been improved to increase the failure detection capability that was in the original CAN FD protocol, which is also called non-ISO CAN FD by CAN in Automation (CiA). A three-bit stuff counter and a parity bit have been introduced in the improved CAN FD protocol, now called ISO CAN FD. The CRC calculation has also been modified. All these improvements make the ISO CAN FD protocol incompatible with the non-FD CAN FD protocol. The non-ISO CAN FD is still supported by FlexCAN so that it can be used mainly during an intermediate phase, for evaluation and development purposes.

Therefore, it is strongly recommended to configure FlexCAN to the ISO CAN FD protocol by setting the ISOCANFDEN field in the CAN\_CTRL2 register.

### 44.4.9.2 CAN FD frames

The ISO 11898-1 standard specifies the Classical Frame format compliant to ISO 11898-1 (2003) and introduces the CAN Flexible Data Rate Frame format. The Classical Frame format allows bit rates up to 1 Mbit/s and payloads up to 8 bytes per frame. The Flexible Data Rate Frame format allows bit rates higher than 1 Mbit/s and payloads longer than 8 bytes per frame. FlexCAN can receive and transmit CAN FD messages interleaved with Classical CAN messages.

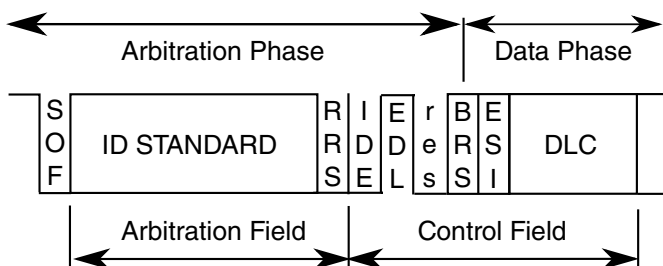

There are three additional control bits in the CAN FD frame. The Extended Data Length (EDL) bit enables a longer data payload with different data length coding. The Bit Rate Switch (BRS) bit decides whether the bit rate is switched inside a CAN FD format frame. The Error State Indicator (ESI) flag is transmitted dominant by error active nodes, and recessive by error passive nodes. There is no Remote Frames (see [Remote frames](#)) in the CAN FD format. A message configured to transmit a Remote Frame is always sent out in the Classical CAN format. When a FD frame is received and matches a mailbox, the RTR bit in the receiving message buffer is negated. The RTR bit must be considered in classical frames only.

CAN FD messages may be formatted as long frames where the data field exceeds 8 bytes, and may range from 12 up to 64 bytes. They can also be configured to support bit rate switching, where the control field, the data field, and the CRC field of a CAN frame are transmitted with a higher bit rate than the beginning and the end of the frame. Messages in Classical CAN format are limited to transport a maximum payload of 8 bytes at nominal rate. The following figure illustrates the message formats for Classical and FD frames with either standard or extended ID.

CAN Standard Format

CAN FD Standard Format

CAN Extended Format

CAN FD Extended Format

**Figure 44-3. CAN message formats**

The ability to receive and transmit CAN FD messages is enabled by the CAN\_MCR[FDEN] bit. Either a recessive R0 bit in CAN frames with 11-bit identifiers or a recessive R1 bit in CAN frames with 29-bit identifiers are decoded as an EDL bit (not a reserved one). A CAN FD frame is recognized by a recessive EDL bit, while a

Classical CAN frame is recognized by a dominant EDL bit. The BRS bit specifies whether this frame switches the bit rate in its data phase. A long frame is decoded in accordance to the DLC field value (see DLC definition in [Message buffer structure](#)).

CAN FD messages can be transmitted with two different bit rates. The first part of a CAN FD frame, from the Start Of Frame (SOF) bit until the Bit Rate Switch (BRS) bit, also called the arbitration phase, is transmitted with the nominal bit rate based on a set of nominal CAN bit timing configuration values. The second part, from the BRS bit until the CRC Delimiter bit, also named the data phase, is transmitted with the data bit rate defined by a second set of CAN data bit timing configuration values. Finally, from the CRC Delimiter until the Intermission bits, the transmission resumes to nominal bit rate. In CAN FD frames with bit rate switching, the bit timing is changed inside the frame at the sample point of the BRS bit if this bit is recessive. Before the BRS bit, in the CAN FD arbitration phase, the nominal CAN bit timing is used as defined by the CAN\_CBT register (also by CAN\_CTRL1 register for backward compatibility). Upon detecting a recessive BRS bit, the CAN data bit timing is used as defined by the CAN\_FDCBT register.

### NOTE

If the length of the time quantum in the nominal bit timing and the length of the time quantum in the data bit timing are not identical, a quantization error of up to one time quantum of the arbitration phase may be present as a phase error. This situation can occur after the switch from arbitration to data phase and will last until the next synchronization event. Thus, the length of the time quantum should be the same in nominal and data bit timing in order to minimize the chance of error frames on the CAN bus, and to optimize the clock tolerance in networks that use FD frames.

CAN\_FDCTRL[FDRATE] enables the transmission of all frames with bit rate switching if the BRS bit in the selected Tx MB is set. If FDRATE is negated, the transmission is performed at nominal rate regardless of the BRS bit value. The CAN\_FDCTRL[FDRATE] bit can be written any time but takes effect only for the next message transmitted or received.

The nominal bit timing is resumed at either the sample point of the CRC Delimiter bit or when an error is detected, whichever occurs first. The following figure describes the mechanism for entering and leaving the data phase when BRS bit is recessive.

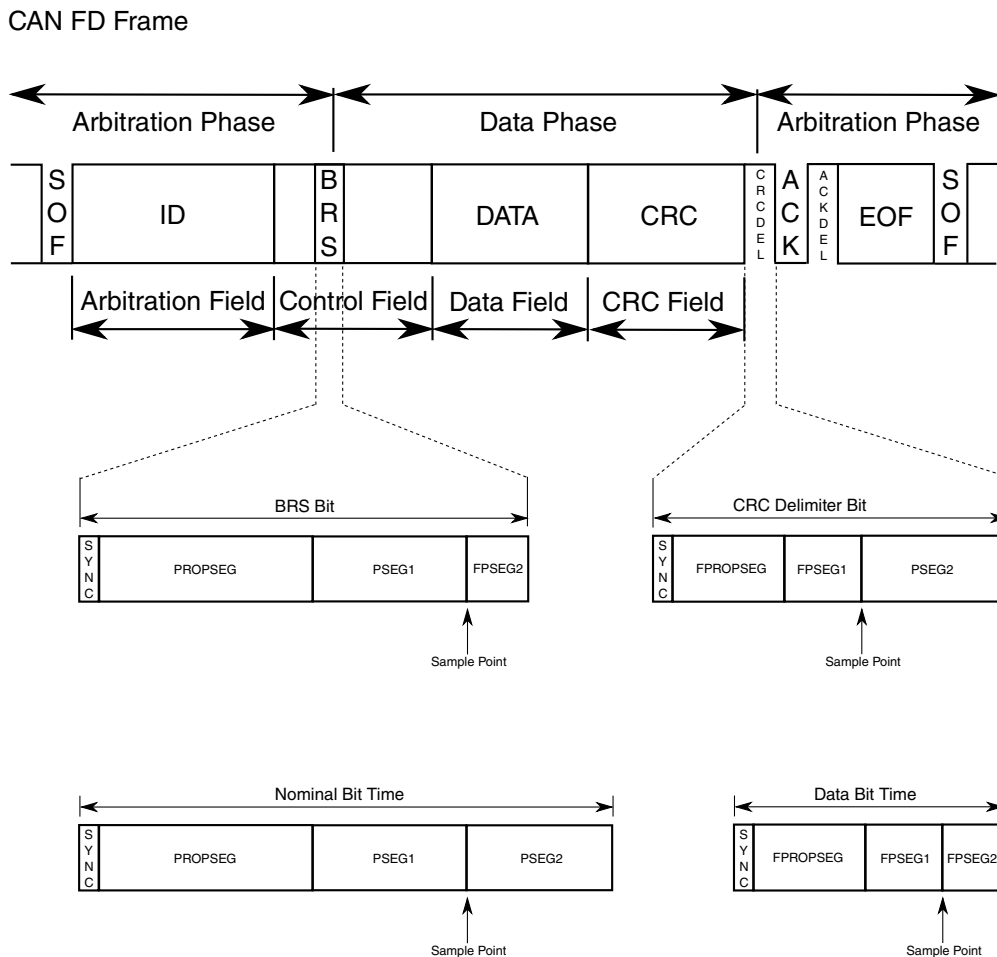

Figure 44-4. Bit rate switching mechanism for CAN FD messages

**NOTE**

In Classical CAN frames, the CRC delimiter is one single recessive bit. In CAN FD frames, the CRC delimiter may consist of one or two recessive bits. FlexCAN sends only one recessive bit as the CRC delimiter, but it accepts two recessive bits before the edge from recessive to dominant that starts the acknowledge slot. As a receiver, FlexCAN sends its acknowledge bit after the first CRC delimiter bit. In CAN FD frames, FlexCAN accepts a two-bit dominant ACK slot as a valid ACK to compensate for phase shifts between the receivers.

The maximum configurable bit rate in the CAN FD data phase depends on the clock frequency of CAN\_PE sub-block. For example, with a CAN\_PE clock frequency of 40MHz and the shortest configurable bit time of 5 time quanta, the bit rate in the data phase is 8 Mbit/s.<sup>6</sup>

The value of the ESI bit is determined either by the transmitter's error state at the start of the transmission, if the frame is originated in the FlexCAN node, or by the original transmitting node in case FlexCAN is acting as a gateway for the message. If the transmitter is error passive, ESI is transmitted recessive; otherwise, it is transmitted dominant. The permutations of the relationship between the written value and the transmitted value of the ESI are shown in this table.

**Table 44-14. Written versus transmitted values of ESI field**

FlexCAN fault confinement status at start of frame	ESI bit Of Tx MB	Transmitted ESI
Error active	0	0 (Error Active)
Error passive	0	1 (Error Passive)
Error active	1	1 (Error Passive)
Error passive	1	1 (Error Passive)

There are different CRC polynomials for different CAN frame formats. The first polynomial, CRC\_15, is used for all frames in Classical CAN format. The second, CRC\_17, is used for frames in CAN FD format with a data field up to sixteen bytes long. The third, CRC\_21, is used for frames in CAN FD format with a data field longer than sixteen bytes. Each polynomial results in a Hamming Distance of 6. At the start of the frame, all three CRC polynomials are calculated concurrently. The CRC sequence to be transmitted is selected by the values of the EDL bit and the DLC bit field. When receiving a message, FlexCAN decodes EDL and DLC to select the adequate CRC polynomial to check for a CRC error.

In CAN FD format frames, stuff bits are included in the bit stream for CRC calculation. In Classical CAN format frames, stuff bits are not included. After the transmission of the last bit relevant to the CRC calculation, the CAN\_FDCRC register stores the calculated CRC for the transmitted message, with the adequate length in accordance to the type of message, for both CAN FD and non-FD messages. The CAN\_CRCCR register reports a valid CRC for Classical CAN messages only.

In CAN FD format frames, the CAN bit stuffing method is changed for the CRC sequence so that the stuff bits are inserted at fixed positions. When FlexCAN is transmitting a CAN FD frame, a fixed stuff bit is inserted just before the first bit of the CRC sequence, even if the last bits of the preceding field do not fulfill the CAN stuff condition. Additional stuff bits are inserted after each fourth bit of the CRC sequence. The value of any fixed stuff bit is the inverse value of its preceding bit. When FlexCAN

6. The frequency used in this example may not be supported on this chip; it is shown only to demonstrate how the maximum configurable bit rate is calculated.

is receiving a CAN FD frame, it discards the fixed stuff bits from the bit stream for the CRC check. A Stuff Error is detected if the fixed stuff bit has the same value as its preceding bit.

FlexCAN detects errors in CAN FD frames the same way as in Classical CAN frames. The error counters RXERRCNT and TXERRCNT in the CAN\_ECR register accumulate the counts of Rx and Tx errors, respectively, for both FD and non-FD frames indistinctly. There are two extra error counters (RXERRCNT\_FAST and TXERRCNT\_FAST) that accumulate Rx and Tx errors occurring in the data phase of CAN FD frames with the BRS bit set only. The rules for updating the error counters are the same for both CAN FD and non-FD frames (see CAN\_ECR register).

Error Flags BITERR1, BITERR0, ACKERR, CRCERR, FRMERR and STFERR in the ESR1 register report errors in both CAN FD and non-FD frames. They also generate the ERRINT interrupt if CAN\_CTRL1[ERRMSK] is asserted. The CAN\_ESR1 register has additional error flags (BITERR1\_FAST, BITERR0\_FAST, CRCERR\_FAST, FRMERR\_FAST and STFERR\_FAST) to individually indicate the occurrence of errors in the data phase of CAN FD frames with the BRS bit set. There is no ACKERR detected in the data phase of a CAN FD frame. Fault confinement status reported in CAN\_ESR1[FLTCONF] is the same for both CAN FD and Classical CAN frames, and is based on RXERRCNT and TXERRCNT error counters only. Information contained in RXERRCNT\_FAST and TXERRCNT\_FAST counters may be considered as status to help detect the error nature related to the bit rate value.

When FlexCAN is in the data phase, either transmitting or receiving a CAN FD message, and detects an error, it immediately switches back to the arbitration phase and to the nominal rate to start an Error Flag.

Resynchronization and Hard Synchronization occur in CAN FD frames in the same way as in Classical CAN ones. Additionally, a Hard Synchronization is also performed at the recessive to dominant edge from EDL to R0 in CAN FD format frames. FlexCAN does not resynchronize while transmitting in the CAN FD data phase.

### **44.4.9.3 Transceiver Delay Compensation**

The CAN FD protocol allows the transmission and reception of data at a higher bit rate than the nominal rate used in the arbitration phase when the message's BRS bit is set. This feature enables the use of rates up to 8 Mbps.

During the data phase of a CAN FD frame, the Transmitter detects a bit error if it cannot receive its own latest transmitted bit at the sample point of that bit. When bit rate switching is enabled (BRS bit is asserted), the length of the CAN bit time in the data

phase can become shorter than the transceiver's loop delay, thus impeding the correct comparison between the transmitted bit and the received bit within the current CAN bit time interval.

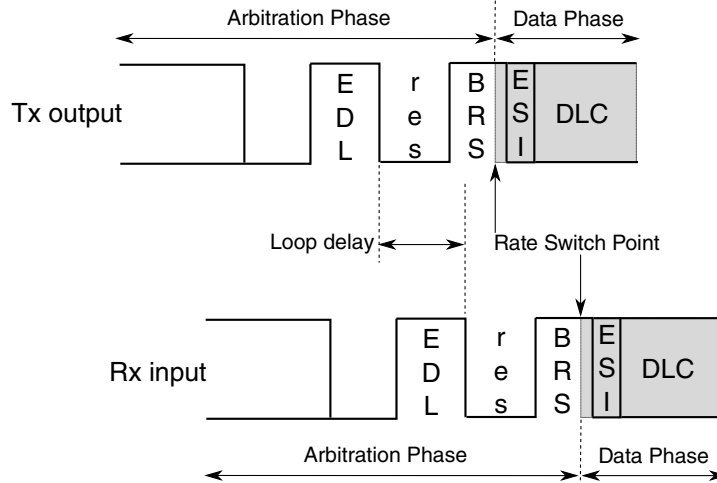

Note that the TDC process defines a secondary sample point where the transmitted bit is correctly compared with the received bit in order to check for bit errors.

The TDC mechanism can be enabled by the CAN\_FDCTRL[TDCEN] bit and is effective only during the data phase of FD frames having the BRS bit set. It has no effect either on non-FD frames, or on FD frames transmitted at normal bit rate. The TDC is active from the sample point of the BRS bit until the sample point of the CRC Delimiter bit, provided the respective message under transmission has the BRS bit set. When it is active, a comparison is done between the real received bit and the delayed transmitted bit, where the delay is calculated based on the measured transceiver loop delay.

### NOTE

The actual value of the CRC Delimiter bit is disregarded by transmitters using the Transceiver Delay Compensation mechanism. A global error at the end of the CRC Field will cause the receivers to send error frames that the transmitter will detect during Acknowledge or End of Frame.

For every transmitted FD frame having the BRS bit set, the delay measurement is triggered by the transition from the recessive EDL bit to the dominant R0 bit (as shown in the next figure). The loop delay is measured in Protocol Engine (PE) clock periods (CANCLK, see [Protocol timing](#)), from the transmitted EDL-R0 edge to the received EDL-R0 edge. The position of the secondary sample point is defined by the measured loop delay time added to an offset value specified in CAN\_FDCTRL[TDCOFF]. CAN\_FDCTRL[TDCVAL] bit field stores the result of this calculation. The TDCVAL value saturates at its maximum value of 63 CANCLK when the delay measurement is too long.

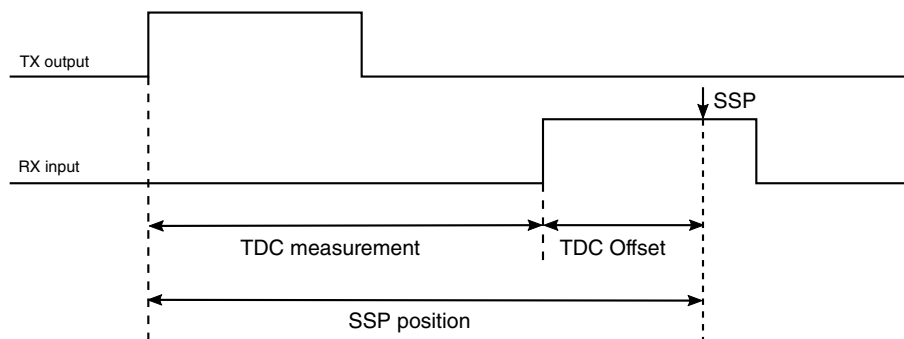

**Figure 44-5. Transceiver loop delay measurement**

The measured loop delay is not enough to be used to define the secondary sample point because it relates to the CAN bit edges. The transceiver delay compensation offset TDCOFF is used to shift the secondary sample point from the edge to an intermediate point inside the bit time, far away from its edges. Therefore, the TDCOFF value cannot be larger than the CAN bit duration in the data phase.

If the secondary sample point is set very near the CAN bit edge (SYNC field), then problems may occur during the bit sampling in the data phase. For the TDC to work reliably, the offset has to use optimal settings. To be sure the bit sampling is performed in the best region, the TDC offset should be configured as shown in this equation:

$$\text{Offset} = \text{PSEG1} + \text{PROPSEG} + 2$$

The following figure shows the SSP position when these settings are used.

**Figure 44-6. SSP position with optimal values**

During the data phase of CAN FD frames with bit rate switching enabled, at the onset of every Tx CAN bit, the transmitted Tx bit value is temporarily stored in a buffer and a time countdown based on TDCVAL is started which ends with the comparison of the

received Rx bit (delayed by the external loop delay plus the specified offset) with the stored Tx bit. If a bit error is detected at the secondary sample point, the FlexCAN issues an error flag to the CAN bus at the next sample point.

During the arbitration phase the delay compensation is always disabled. The maximum delay which can be compensated by the FlexCAN's transceiver delay compensation during the data phase is 3 CAN bit times - 2 T<sub>q</sub>. Beyond this limit, the CAN\_FDCTRL[TDCFAIL] flag is set to indicate when the Transceiver Delay Compensation mechanism is out of range, unable to compensate the transceiver loop delay.

#### 44.4.9.4 Remote frames

Remote frame is a special kind of frame. The user can program a mailbox to be a Remote Request Frame by configuring the mailbox as Transmit with the RTR bit set to '1'. After the remote request frame is transmitted successfully, the mailbox becomes a Receive Message Buffer, with the same ID as before.

When a remote request frame is received by FlexCAN, it can be treated in four ways, depending on Remote Request Storing (CTRL2[RRS]) and Rx FIFO Enable (MCR[RFEN]) bits:

- If RRS is negated the frame's ID is compared to the IDs of the Transmit Message Buffers with the CODE field 0b1010. If there is a matching ID, then this mailbox frame will be transmitted. Note that if the matching mailbox has the RTR bit set, then FlexCAN will transmit a remote frame as a response. The received remote request frame is not stored in a receive buffer. It is only used to trigger a transmission of a frame in response. The mask registers are not used in remote frame matching, and all ID bits (except RTR) of the incoming received frame should match. In the case that a remote request frame is received and matches a mailbox, this message buffer immediately enters the internal arbitration process, but is considered as a normal Tx mailbox, with no higher priority. The data length of this frame is independent of the DLC field in the remote frame that initiated its transmission.
- If RRS is asserted the frame's ID is compared to the IDs of the receive mailboxes with the CODE field 0b0100, 0b0010 or 0b0110. If there is a matching ID, then this mailbox will store the remote frame in the same fashion of a data frame. No automatic remote response frame will be generated. The mask registers are used in the matching process.
- If RFEN is asserted FlexCAN will not generate an automatic response for remote request frames that match the Legacy FIFO filtering criteria. If the remote frame matches one of the target IDs, it will be stored in the Legacy FIFO and presented to

the CPU. Note that for filtering formats A and B, it is possible to select whether remote frames are accepted or not. For format C, remote frames are always accepted (if they match the ID). Remote Request Frames are considered as normal frames, and generate a Legacy FIFO overflow when a successful reception occurs and the Legacy FIFO is already full.

- If ERFEN is set, FlexCAN will not generate an automatic response for remote request frames that match the Enhanced Rx FIFO filtering criteria. Remote Request Frames are considered normal frames, and generates a Enhanced Rx FIFO overflow when a successful reception occurs and Enhanced Rx FIFO is already full.

### **NOTE**

There is no remote frame in the CAN FD format. The RTR bit is replaced by a fixed dominant RRS bit. FlexCAN receives and transmits remote frames in the Classical CAN format.

#### **44.4.9.5 Overload frames**

FlexCAN does transmit overload frames due to detection of following conditions on CAN bus:

- Detection of a dominant bit in the first/second bit of Intermission
- Detection of a dominant bit at the 7th bit (last) of End of Frame field (Rx frames)
- Detection of a dominant bit at the 8th bit (last) of Error Frame Delimiter or Overload Frame Delimiter

#### **44.4.9.6 Message buffer time stamp**

The value of the Free Running Timer is sampled at the beginning of the Identifier field on the CAN bus, and is stored at the end of "move-in" in the TIME STAMP field of message buffer, providing network behavior with respect to time.

When the TIMER\_SRC bit in CAN\_CTRL2 register is asserted, the Free Running Timer is continuously clocked by an external time tick.

When the TIMER\_SRC bit in CAN\_CTRL2 register is negated, the Free Running Timer is clocked by the FlexCAN bit-clock, which defines the baud rate on the CAN bus. During a message transmission/reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate.

The Free Running Timer is not incremented during Disable, Doze, Stop, and Freeze modes. It can be reset upon a specific frame reception, enabling network time synchronization. See the TSYN description in Control 1 Register (CAN\_CTRL1).

Alternatively, by configuring the MTSBASE field of the Control 2 Register (CAN\_CTRL2), the time stamp of the message buffer can capture the lower or higher 16 bits of the high-resolution dedicated counter.

#### 44.4.9.7 High resolution time stamp

The high-resolution time stamp, CAN\_HR\_TIME\_STAMP, uses a dedicated timer with a 32-bit counter operating in free running mode. The high-resolution time stamp is enabled by the TSTAMPCAP field of the Control 2 Register (CAN\_CTRL2). When this field is not zero, the dedicated 32-bit counter value is captured during a valid CAN frame and stored in the CAN\_HR\_TIME\_STAMP register.

Each CAN\_HR\_TIME\_STAMP $n$  corresponds to a specific message buffer. For example, the CAN\_HR\_TIME\_STAMP0 stores the 32-bit time stamp associated with Message Buffer 0, CAN\_HR\_TIME\_STAMP1 stores the 32-bit time stamp associated with Message Buffer 1, and so on.

The counter value is captured according to the TSTAMPCAP field of the Control 2 Register (CAN\_CTRL2). For classical CAN frames, the capture points can be the start of frame bit or the point in time a CAN frame is considered valid, which is the seventh bit of end of frame for transmission and the sixth bit of end of frame for reception. For CAN FD frames, the capture points can be the start of frame, the point in time a CAN FD frame is considered valid, or the res bit of a CAN FD frame.

The 16-bit time stamp of the message buffer can be configured to capture the lower or higher 16 bits of the high-resolution timer. This configuration is made by CTRL2[MBTSBASE].

#### 44.4.9.8 Protocol timing

The following figure shows the structure of the clock generation circuitry that feeds the CAN Protocol Engine (PE) submodule. The clock source bit CLKSRC in the CAN\_CTRL1 Register defines whether the internal clock is connected to the output of a crystal oscillator (Oscillator Clock) or to the Peripheral Clock. In order to guarantee reliable operation, the clock source should be selected while the module is in Disable Mode (MDIS bit set in the Module Configuration Register).

**NOTE**

Please refer to the clock distribution chapter (module clocks table) to identify the proper clock source.

**Figure 44-7. CAN engine clocking scheme**

The oscillator clock should be selected whenever a tight tolerance (up to 0.1%) is required in the CAN bus timing. The crystal oscillator clock has better jitter performance than the peripheral clock.

The FlexCAN module supports a variety of means to setup bit timing parameters that are required by the CAN protocol. The Control 1 Register (CAN\_CTRL1) has various fields used to control bit timing parameters: PRESDIV, PROPSEG, PSEG1, PSEG2 and RJW.

The CAN Bit Timing register (CAN\_CBT) extends the range of the CAN bit timing variables in CAN\_CTRL1. The CAN FD Bit Timing register (CAN\_FDCBT) provides a second set of CAN bit timing variables to be applied at the data phase of CAN FD frames with the Bit Rate Switch (BRS) set.

**NOTE**

When the CAN FD feature is enabled, always set CAN\_CBT[BTF] and configure the CAN bit timing variables in CAN\_CBT. See [CAN Bit Timing Register \(CBT\)](#).

The PRESDIV field (as well as its extended range EPRESDIV and FDPRESDIV for the data phase bits of CAN FD messages) defines the Prescaler Value (see the equation below) that generates the Serial Clock (Sclock), whose period defines the 'time quantum' used to compose the CAN waveform. A time quantum (Tq) is the atomic unit of time handled by the CAN engine.

$$Tq = \frac{(PRESDIV + 1)}{f_{CANCLK}}$$

The bit rate, which defines the rate the CAN message is either received or transmitted, is given by the formula:

CAN Bit Time = (Number of Time Quanta in 1 bit time) \* T<sub>q</sub>

$$\text{Bit Rate} = \frac{1}{\text{CAN Bit Time}}$$

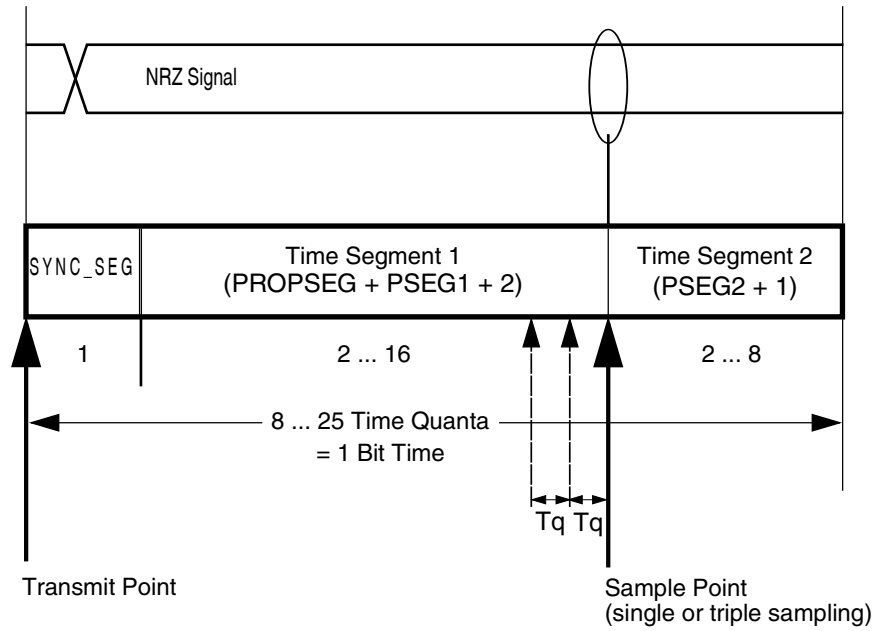

A bit time is subdivided into three segments<sup>1</sup> (see [Figure 44-8](#), [Figure 44-9](#) and [Table 44-15](#)):

- **SYNC\_SEG:** This segment has a fixed length of one time quantum. Signal edges are expected to happen within this section
